Suppose two men of equal height to be standing—one, which we will call A, opposite to the eye of a spectator—the other, B, at a distance greatly to the right, but the latter quite close to the plane of the picture, the former at a distance from it. Now, in this case, the man at B will be drawn life-size upon the picture, while the man at A will be drawn less than life-size; that is to say, the man who is farthest from the spectator will be represented as larger than the man who is nearest to him. This shows the absurdity of plane perspective when the field of view embraces a wide angle. The absurdity would not, however, be apparent if, when viewing the picture, the eye were confined strictly to the proper point of sight, and the side objects viewed very obliquely; but that is not the way in which pictures are looked at. In order to get distinct vision of the whole picture, the spectator takes a position about twice the breadth of the picture from it, and, in order to inspect more closely the separate points, he walks up to them, and brings the eye directly opposite to the part which he is examining. No one would ever dream of walking close up to the middle of a very wide picture, and looking at the ends of it obliquely from that station. It follows, therefore, that plane perspective will not do for views which contain a very wide angle. Even in correct drawings in plane perspective which include the moderate angle of 45°, there is something strange, unintelligible, and inartistic about the shape and size of the marginal objects.

It is evident, therefore, that if we wish to take a picture including a wide field of view, we must give up the idea of taking it upon a flat surface. If it were possible to construct a lens which should include a field of 120° upon a flat surface, the picture would be a hideous caricature.

The proper kind of perspective for a wide angle of view is panoramic perspective, and the proper surface for taking a panoramic picture upon is a vertical cylinder, with the eye at the centre.

But, in viewing a cylindrical panoramic picture from the centre, we can see only one part at a time. The eye is not a panoramic lens with a diaphragm in the centre, so that everything can be seen distinctly at once, but a lens with the diaphragm or pupil in front, and it only gives distinct vision of one object at a time. Watch any one reading a large folio volume of old and faded type: how his head moves from one end of a line to the other, and back again, so as to bring the eye opposite to each word in succession, in order that he may see it most distinctly! But it matters not whether, keeping the eye at the centre of the cylinder, we turn its axis round to the different parts of the picture in succession, or whether we flatten out the cylindrical picture, and view its separate parts, by giving the eye a motion of translation along it, so as to bring its axis opposite and perpendicular to the different objects in succession. It matters not whether we perform a pirouette upon our heel in the centre of one of Mr. Burford's panoramic views—or whether we spread the picture out flat, and view it while walking upon a stage parallel to it—or whether, while we stand still, a small portion of it at a time is brought into view by being unwound from one vertical cylinder and wound upon another. All these plans are right in principle, and involve no absurdity; because, in all panoramic pictures, the farther a thing is off the smaller it is represented, and the common sense of the spectator is not outraged or his wits puzzled by unintelligible freaks of perspective at the sides of the picture.

If a panoramic picture is spread out flat, and the eye placed at such a distance from it that the whole can be included at one glance, the spectator might be puzzled, did he not, by comparing the small height of the picture with its length, and the multiplicity of objects included in that length, become aware at once that it was not in ordinary plane perspective, and, consequently, not intended to be viewed in that way. Nevertheless, from the graceful axis of the vanishing lines, the long flowing lines of the composition, and the absence of all misshapen, distorted, and unintelligible representations of things, panoramic pictures flattened out are not only vastly more interesting than common views, but infinitely more artistic.

If a crescent of equal and similar houses were taken by a panoramic lens placed at the centre of the crescent, the picture when flattened out would be the same as if the houses had been placed in a straight row, and taken upon a flat picture parallel to them. One could not, therefore, tell how such a picture had been taken unless a description were appended to it. But this would not constitute a special objection to the panoramic picture, because it would cut both ways. Tell us what lens the picture was taken by and then we know all about it.

Towards the close of the Crimean war Mr. Robertson, of Constantinople, took from the same station three views of Sebastopol, so as to form, when mounted side by side, a sort of panoramic picture, including an angle of about 100°. Although it possessed extraordinary interest, one could not help regretting the defects occasioned by the joinings of the prints, which being better in definition and more strongly lighted in the centre than at the edges, the three patches of light and two dark joinings did not look well. But when the panoramic lens is employed, and the whole picture taken at once, the definition is equally good along the whole horizontal line, and the light equally distributed.

It is evident, from what has been said, that plane perspective is wrong in theory for pictures which include a wide angle, and panoramic or cylindrical perspective quite correct.

When the axes of all the pencils pass straight through the centre of a panoramic lens without suffering deviation, the image upon the cylinder is geometrically correct, and absolutely free from distortion.

ON PHOTOGRAPHIC PRINTING UPON PAPER.

By W. T. Mabley.

[Read at the Meeting of the Manchester Photographic Society, April 4, 1860.]

In the early days of photography—indeed until very recently—printing from a negative was considered to require but very little care or experience; it was looked upon as one of those things that anybody could do, and men of science thought it beneath their investigation. The fading of prints, however, aroused them from this dream, and in endeavouring to overcome that evil, results have been arrived at which give us, so far as we can at present judge, the thing we sought, and, in addition to that, an artistic effect which was not contemplated. If now, therefore, it should happen that we have the means of producing permanent prints, their having faded has been a most fortunate occurrence, and we must look upon it as having been a blessing in disguise; for who is now satisfied with that dirty yellow which so often disfigures a print fixed and toned after the old method? But although printing has now received considerable attention, it has appeared to me that several matters which might or might not be of importance have never been practically and sytematically examined. The condition of the nitrate bath, for instance, which, as we all know, can in negative photography affect the results immensely, might, it appeared, be also of great importance in printing upon paper, not only in reference to sensitiveness, but in imparting facilities for pleasing and economical effects in tone. On taking up this subject I determined, therefore, to examine separately the several divisions, and to determine, if possible, what might and what might not be done, and to establish, if possible, the conditions necessary for producing the best results.

Before I give you the results of my experiments, I think it necessary to explain the method I adopted in conducting them. I wish particularly to do this, because there is, as we all know, a great disposition among photographers to jump at hasty conclusions, and to enunciate as facts things that rest upon very slight investigation. This conduct cannot, I think, be too highly censured; it brings discredit upon the art, and wastes the time and money of those who have not yet learned, from bitter experience, how little dependence is to be placed upon the so-called facts which are lavishly given to the world. I say this, feeling that I myself may be found wanting in some things; but I shall, at any rate, place before you results which you can see, together with a minute account of the means that were adopted for producing them; and you will therefore be in a position to judge of the value which may be placed upon my statements.

Many of the examples of which I shall have to speak are founded upon comparative experiments, and these could not have been properly carried out by negatives I had by me; because it would have been impossible to select, even out of a large number, three or four which would produce the same character of print, or require the same exposure. I therefore determined to make negatives for the purpose, with regular gradations of light and shade over the entire surface; and the method, after several trials, which I found to answer best, was to cause the light to pass through strips of paper of different degrees of transparency. Having obtained a negative in this way, I could, by placing separate pieces of paper, prepared in different ways, upon it, obtain as many pictures by simultaneous exposure, each one being acted upon by exactly the same amount of light, and representing the same gradations of light and shade. The results of the experiments so conducted I will now lay before you; but they must be considered only as a commencement made, and as hints which point out the direction in which future examinations must be carried on.

So much more time has been required than I expected or than I could spare from my own profession, and I have been so perplexed by uncertain weather, that I must omit much I had intended to have included in the present paper.

The first thing to which I directed my attention was the sensitiveness of prepared papers as affected by various conditions of the nitrate bath. There has been a general idea that this bath must be strong, but of what particular strength it should be it has been uncertain; it has also, so far as I know, been doubtful whether it should be acid or alkaline, or whether impurities arising from a mixture of organic matters, or other such substances, affected it. In reference to the strength of the bath, it is well known that it must depend upon the quantity of salt employed in the first preparation. Chloride of silver will darken with a small excess of free nitrate, but it requires a considerable excess to afford a brilliant picture. The chemical action which gives rise to the substance constituting the picture is a matter of dispute with the learned; but it appears to me that the most reasonable explanation which has been given is, that the layer of chloride of silver becomes decomposed, giving off chlorine, which unites with a quantity of the free nitrate, so as to form another film of chloride, and so on. But whatever the chemistry may be, it is certain that a considerable excess of free nitrate is required: and here our first difficulty comes upon us, for we buy our albumenised paper, and are in total ignorance as to the quantity of salt used in the albumen. It should be remarked, too, that the equivalents of the salts used vary: between that of ammonium and sodium the difference is not very great, ten of the former being equal to eleven of the latter, but it requires twice as much chloride of barium. It is therefore greatly to be desired that makers of albumenised papers would stamp each sheet with the name of the salt used, and with the number of grains to each ounce of albumen.

The paper I employed for the purpose of my experiments was salted with ten grains of chloride of ammonium to the ounce of albumen, unless otherwise mentioned, and I adopted a sixty-grain nitrate bath as the standard by which to compare others. All the baths I shall mention were made for the purpose from crystallised nitrate of silver. The standard bath of sixty grains gave, as is usual, a faint acid reaction to test paper, so that there was a small quantity of free nitric acid present.

The various pieces of paper were floated on the baths for exactly the same time, viz., six minutes, and were dried in a warm room without being held near to the fire, and, for the present purpose, that is the comparison of sensitiveness. The prints were fixed, without toning, in fresh hyposulphite of soda, in which they remained exactly the same time, and were then quickly washed. I adopted this plan because the action of toning might in some cases have masked the degree of sensitiveness. The first trial was a comparison of paper prepared with a sixty-grain and ninety-grain nitrate bath. Here is the result, two samples being given, and I think you will hardly be able to detect any difference: there is, perhaps, a slightly increased bronzing of the darkest shade due to the ninety-grain bath—it is, however, but slight. The next trial was a comparison with a bath which, with additions at times of nitrate of silver, has been in use for about two years, there having been at times old negative baths added to it, so that it must contain a considerable quantity of substances which were not intended to be there, not only from that source, but from the chlorides with which the papers were salted, and from gelatine and other matters used in sizing by the maker, and in preparing papers for plain printing; but on examining the prints you will scarcely perceive any difference as regards the sensitiveness of the paper. The next bath employed was neutralised, and a further quantity of alkali added so as to give it a faint alkaline reaction to test paper: here is the result, and you will perceive again that there is not any difference of consequence in the sensitiveness. Here are examples of a comparison between the standard bath and another in which were two drops of nitric acid to the ounce, and still the sensitiveness remains nearly the same; the standard bath has, however, the advantage slightly. The next experiment was with paper floated for different lengths of time—one being allowed to remain in the bath for half an hour, and the other for the standard time of six minutes. Here is the result, and the sensitiveness is still unaffected: here are two prints, the one being on paper prepared with ten grains of chloride of ammonium to the ounce of albumen, and the other on paper prepared with fifteen grains to the ounce, both floated on a nitrate bath of ninety grains to the ounce: here is a most marked difference—it is not preceived so much in the lighter shades, but in the darker the paper prepared with fifteen grains of chloride is much more bronzed, and the whole tone of the print is more intense.

Now looking at sensitiveness alone it does not appear from the foregoing experiments that the condition of the nitrate bath is of that importance which might have been imagined; but it does appear that the quantity of chloride of silver formed upon the paper influences the sensitiveness considerably; and the general aspect of the print would give promise of an exalted toning quality. But the consideration of that is left for the next division; at present I merely refer to sensitising.

It must be left for future trials to determine the most suitable strength of nitrate bath for paper salted in this manner; but taking it at ninety grains it certainly gives results superior to ten grains salted paper floated upon the same bath.

There is another matter connected with sensitiveness which I am enabled to illustrate in a striking manner. Mr. Pyne has favoured me with a piece of paper, which has been kept sensitised for six months in one of Messrs. Marion's cases. On removing it yesterday

I found it but very slightly discoloured, not so much so as paper frequently becomes by being kept in a room for twenty-four hours. I expected, however, to find that its sensitiveness was materially weakened; but, to my astonishment, on printing upon it, together with another piece freshly prepared and from the same negative, I found it to be more sensitive. This, however, must not be taken as an experiment which shows that paper improves by keeping; for it must be borne in mind that I was unacquainted with the mode in which it was prepared, and that some makes of paper are more sensitive than others. I think, however, that taking it as an average sample, we may fairly assume that positive paper does not suffer in sensitiveness by long keeping. I received another piece of this paper for my inspection, and a third I printed upon for toning, the result of which I shall presently show you.

There is one more matter connected with sensitiveness which I have experimented upon: it is the quantity of light obstructed by the thick glass used in printing frames. Here is a print from a negative covered with the usual thick glass, and here is another printed without that covering. The two negatives are cut out of the middle of a large plate, after a negative of that size was taken to secure the same printing qualities, and the two pieces of paper were cut from the same sheet after it was sensitised.

You will perceive that the difference in the prints is very great, printed even as they were in bright sunshine: on a dull day we should, I expect, find a far greater contrast.

It is difficult to estimate the extra printing which the thick glass renders necessary, because the light may not continue the same while the last is being finished; but I believe, from observations I have made, that in dull weather the difference would amount to twenty or thirty per cent. It will be obvious that, when many copies from a negative are wanted, this is an important matter, and when that is not the case it is still of advantage to the amateur, who has but few hours to devote to photography.

(To be concluded in our next.)

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 2.

The art of commenting upon the sayings and doings of others is not a secret in the possession of one person only, but is understood more or less by us all. Of this the author of these letters has lately experienced a proof; for, whilst he was examining, in a critical manner, the statements and analyses of our friends on the other side of the channel, the same process was, without his consent, being applied to himself much nearer home. The proceedings which took place at the last meeting of the Blackheath Photographic Society have been fully reported in the journals, and the reading portion of the photographic public are doubtless familiar with them. Mr Heisch is the exponent of the views of that society, and it is certain that he has stated everything which was necessary to make a strong case.

The writer of this letter declined, in the first instance, becoming a member of the Collodion Committee; but, inasmuch as his interests were not likely to be affected by the Report in the way which Mr. Heisch supposes, there appeared no impropriety in his attending the meetings of the committee from time to time, and even in his being present when the Report was agreed upon: thus he understands the opinions and experiments of the committee, and is in a position to reply to the arguments of Mr. Heisch.

An impartial observer, taking a cursory glance at the proceedings of the Blackheath Society, would perhaps be struck with the observations of the speakers, and wonder equally with them how a number of gentlemen could commence their Report by stating the defects of a collodion, and end it by recommending the society to adopt that formula. The difficulty, however, ceases when it has been explained that the committee found other collodions which they had used previously, and were using simultaneously, to be in the same predicament. Like optical lenses, collodion seems to lose in one direction what it gains in another; and, therefore, all that can be done is to reduce the errors to a minimum, and to select that formula which appears to offer the most advantages. Consider, also, the difficulty of comparing collodions with each other in so complete a manner as to satisfy all. It has been said, "Try them under similar circumstances, and the result will be conclusive!" but this inference is an unfounded one, as may be proved by the experiments of the Collodion Committee themselves; for, whereas one member states that he tried another collodion, and found it to give the picture in one-half of the time, a second member says that he also tried that same collodion, and proved it to be inferior in sensitiveness to the collodion supplied to the committee. It is probable that there were differences of manipulation not taken into account, or that one collodion was more prone to drying and consequent loss of sensitiveness than the other. Neither does it appear impossible that the constitution of the developer may have influenced the result, for there exists a state of film in which, after passing through the bath, nitric acid is present, due to traces of iodine in the collodion; and when such is the case, it is presumed that the same quantity of acid cannot be tolerated in the developer. In another sample of collodion intended for comparison with the first, the reaction of the iodide of silver, on leaving the bath, may be alkaline, perhaps from a minute quantity of ammonia left after washing the pyroxyline, and, if so, a stronger acid in the reducing agent would restore the balance. These ideas are not merely theoretical, but strictly practical as well; for who has not noticed, when using a colourless collodion free from iodine, that, in a strong light, the image develops with great rapidity and detail, but that there is over-action in the sky. On looking at the plate, the photographer exclaims at once—"The collodion is alkaline; I shall get a better picture by adding citric acid to the developer, or by dropping tincture of iodine into the collodion itself until it becomes yellow!" This question, indeed, appeared so interesting, that the author of these letters, on seeing Mr. Morgan's report, in which he complained of a want of sensitiveness, was induced to write to him at once, and inquire whether there could have been any mistake. He received, however, a reply, saying that the facts were certainly such as had been stated, and that there was no mistake. In another part of his letter Mr. Morgan went on to describe what he considered as the characteristics of the committee collodion, and spoke of it as a good and useful preparation, not sensitive, but producing clean and well-defined pictures, the image sometimes rather intense than otherwise, but with no tendency at all to solarisation, even after a long exposure. The other member of the committee, whose evidence on this particular point was opposed to that of Mr. Morgan, spoke of the sensitiveness as something quite remarkable, but the image a trifle too weak, and with a little tendency to fogging, unless the collodion had been kept for a time in the iodised state. Now, all those who know Mr. Morgan, and also Mr. Hughes (for it is better to mention his name), will have confidence that the facts were such as they have described. How, then, did it happen that four pints of collodion, taken from the same bottle, gave such different results? The cause may perhaps have been due to a more acid condition of the film during development in the one case, and a less acid state in the other. Mr. Morgan praises the collodion for not solarising; but in my own practice I have been sometimes annoyed with solarisation, and, when the light has been very strong, have worked more to my satisfaction, either with collodion made from a softer quality of pyroxyline, or with the same collodion, after the addition of a bromide. An addition of citric acid to the developer, however, remedies the defect of over-action of light, although it renders necessary a longer exposure in the camera.

ON A NEW DRY COLLODION PROCESS,

Being the substance of a Paper read at the Chorlton Photographic Society, April 11, 1860.

By William Griffiths.

I shall make no apology for introducing to your notice this evening a subject in which I presume all of us are more or less interested, namely, that of a good yet simple dry collodion process.

I should probably have displayed more prudence if I had delayed calling your attention to it until I could have spoken of it with the confidence of an operator who had worked it successfully for a whole season. But although I have not as yet tried more than a dozen plates, I am certain from their behaviour, as well as for the chemical reasons which first led me to try it, that it is destined to become no mean rival of the Fothergill or even the collodio-albumen process. Those of you who are invariably successful with the two last-named processes will not be easily persuaded to give them up whilst that success continues; but those who are not so fortunate (and I am persuaded there are many) will do well to give a fair trial at least to the method I will now lay before you.

The great elements of success in any dry collodion process are, in my opinion, the employment of perfectly clean plates, non-contractile, or what is generally termed powdery, collodion, and thoroughly washing after the sensitising bath.

There is no necessity for my troubling you with any lengthened

description of the manipulation required, as it is neither more nor less, up to a certain point, than that of the ordinary wet process.

Take care the plates are as nearly as possible chemically clean, and perfectly dry previous to coating them with collodion. This latter should be of the kind before mentioned; but if any difficulty be experienced in obtaining it, any other will do, though perhaps not quite so well, if the precaution is taken of running a camel-hair brush, dipped in spirit varnish, all round the edge of the plate previous to developing it, otherwise the film will most likely split up when it comes to be dried.

With contractile collodion this is sure to occur when this latter precaution is not taken. Let the film set well before immersing the plate in the nitrate bath, and when the sensitising process is complete put it into a dish of clean filtered water, which should be changed several times. I prefer a wooden trough, inclined at an angle, and so arranged that a gentle stream of water flows in at the upper part over the plate or plates, and out at the lower. While this washing is going on, you of course proceed with the preparation of other plates; and when you have, say half a dozen, in the wash dish or trough, you take out the first one put in, drain for about a minute on blotting paper, then pour over it, as you would do albumen in the Fothergill process, ordinary fresh milk—if after the cream has been taken from it all the better, so that it is perfectly free from acidity. Let it remain on for about a minute, then wash it well off under a gentle stream of water or in the washing bath; drain on blotting paper, and let it dry spontaneously; or, what is still better and more convenient, put the plates when well drained into an air and light-tight box, in which is a saucer, or other convenient vessel, containing an ounce or two of chloride of calcium. By this means the plates are more effectually dried, and are at the same time preserved from the noxious vapours generally floating in the atmosphere of the dark room.

The exposure required, as far as I can judge from the limited experience I have had of them, is about the same as the two processes before named.

The development is the same as in the Fothergill process, but is if anything more rapid. An extremely small quantity of silver is required, say three or four drops of a thirty-grain solution for a stereoscopic plate.

There does not appear to be the slightest tendency to stains or fogging during development, if perfect cleanliness is observed; and in this respect it has a great advantage over the other two processes.

I prefer fixing with a weak solution of cyanide of potassium.

The keeping properties of the plates can only be determined by experience; but I do not see any reason why that should not be equal, and even superior, looking at it from a chemical point of view, to that of the others.

All processes in which albumen forms a constituent of the sensitive surface are of necessity slowly acted on by actinic influence, besides being extremely liable to a species of spontaneous decomposition when kept for any length of time, especially at that season of the year when their services are more particularly required.

The action of the milk on the sensitive surface I conceive to be this:—The phosphates and chlorides which it contains, on coming in contact with the minute portion of free nitrate of silver which is retained mechanically by the particles of iodide in the film, however much it is washed, becomes converted into phosphate and chloride of silver; at the same time a small portion of casein, rendered insoluble, is precipitated in the pores of the film.

I am not sure also whether the sugar of milk is not retained to a small extent, and is useful in accelerating the development.

On some future occasion, after a more lengthened investigation and experience, I may perhaps be allowed to enter more fully into what I believe to be the chemistry of the subject, as well as that of the dry processes generally.

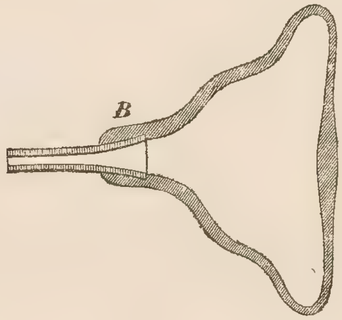
ON VARIOUS KINDS OF GLASS, WITH REFERENCE TO THEIR APPLICATION TO PHOTOGRAPHIC PURPOSES.

By J. A. Forrest.

(Continued from page 64.)

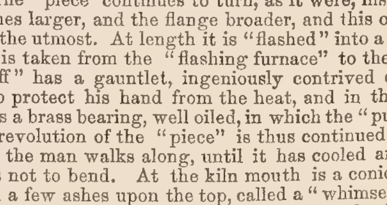
Having secured the pear shape and proportionate thickness, the "blower" re-heats it in the "Patteson hole," and on withdrawing it, it is blown out so as to still further enlarge the widest part. The pipe is supported on an iron "stake" with a broad notch at the top, and the point is pressed into a recess at the end of an iron rod, called the "bullion socket," and held by a lad in a low iron fork. The bullion socket cools and prevents the expansion of the little button at the end, and it also supports the end or "bottom" of the "piece" against the breadth, allowing the workman to complete the top or "shoulder" without making the "bottom" too thin. From the "bullion socket" the blower proceeds to the "bottoming hole"—a furnace similar to the Patteson hole, but of much larger dimensions. The piece is twice reheated in this furnace, and blown out each time, eventually taking the shape of a globe thinner at one pole than the other. A third heat is now taken, and the pipe being turned out rapidly, a well known result ensues—the globe is enlarged at the equator and flattened at the thin soft pole, and being immediately taken from the furnace, it has the shape of *Fig* 1. It is laid across a box containing soft ashes, and an iron rod or "punty" having been heated at the end, and the point dipped into some "glass," it is brought by an attendant and stuck

FIG. 1.



to the bullion at A, the hot metal and "piece" firmly uniting. A short iron rod dipped in water is applied to the neck at B, and causes various small cracks: a blow on the pipe with the wooden mallet breaks the "neck" at that spot, and separates the "piece" from the pipe, leaving an opening about two-and-a-half inches in diameter. The blower marks his number with chalk near the bullion—each man being paid for the number of good tables he makes—and his work upon the "piece" is ended. The "punty sticker" lifts it up by the "punty" and carries it to the "nose hole," a very small but intensely heated reverberatory furnace, with a small circular aperture. Here the "neck" broken from the pipe, and comparatively cold, is reheated, and then rolled upon a board to round off its sharp edges, and the "piece" is delivered to the "piece opener" at the "flashing furnace"—another reverberatory furnace of very large dimensions, very hot, and full of flaming fuel, with a large circular aperture at the side, through which the whole piece is reheated. It is now turned round more rapidly, the first effect of the centrifugal force thus acquired being to flatten the other pole of the former globe. The rotation being continued and increased, and the glass more softened by the heat, the hole expands, and at length turns outwards as in *Fig* 2. The turning

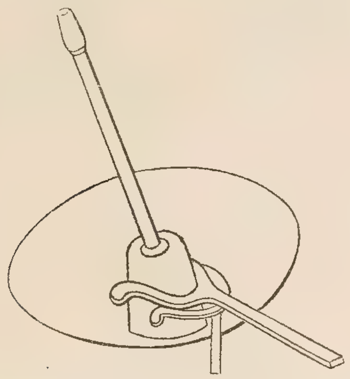
FIG. 2.



is now carefully managed and maintained, for the glass is nearly melting. The "piece" continues to turn, as it were, inside out; the hole becomes larger, and the flange broader, and this opening continuing to the utmost. At length it is "flashed" into a flat circular plate, and is taken from the "flashing furnace" to the kiln. The "carrier off" has a gauntlet, ingeniously contrived of sheet tin and felt, to protect his hand from the heat, and in the hollow or bend of it is a brass bearing, well oiled, in which the "punty" freely runs: the revolution of the "piece" is thus continued by its own impetus as the man walks along, until it has cooled and stiffened so much as not to bend. At the kiln mouth is a conical block of wood, with a few ashes upon the top, called a "whimsey." As the "carrier off" comes with the finished piece towards the kiln, the assistant, or "sister," as he is sometimes called, lays a large two-pronged fork or "horns" across the "whimsey." The "carrier off"

then rests the "bullion" upon it, the table being nearly horizontal, as in *Fig* 3; and the kilnman detaches the "punty" with a pair of

FIG. 3.



shears. The assistant immediately lifts up the "horns" with the "table" resting flat upon them, and passes them through a long narrow opening into the kiln, where it is reared and "piled" up upon its edge by the kilnman. There are two "piles" in the kiln, and the tables are "piled" alternately to each. The first rest against the back wall of the kiln; but after about twenty or thirty are together, a "drosser" is put up. This implement consists of an iron frame, with a projection at right angles from one end. It is reared up near the glass, but not touching it, and the projection passes over the top of the tables and rests against the wall. After another score or so of tables have been "piled," a fresh "drosser" is reared up, the projection also passing over the top of the "table" and resting against the first "drosser," and so on until the "pile" is completed and divided into five or six sections. Any accident happening between two "drossers" is confined to that division of the "pile," and further mischief is prevented. The kiln holds about 350 to 400 tables each.

The glass is allowed forty-eight to sixty hours for annealing: it is then taken from the kiln and cut in two, by a straight line, a few inches from the "bullion." The "half-tables" are either packed in crates for sale, or cut into squares to order; in either case the article itself, and the use of diamonds, are too well known to need comment.

In the process of annealing, crown glass acquires a slight bend, which unfits it for covering prints and photographs; this difficulty is overcome by taking the "small half" (without the "bullion") and placing it upon a perfectly flat stone in the kiln, and whenever it is seen to fall flat, the fire is removed, and it is allowed to re-anneal.

In the course of manufacture, should the coals be impregnated with sulphur, it will give to the glass a milky appearance, and if the photograph is taken upon that side it is sure to result in a foggy picture. The process of polishing lessens this liability, but not always. There is another difficulty in crown glass, arising from dust affixing itself to the outer surface while the piece is at the "nose hole:" this gives roughness to the surface, which the photographer can easily detect by passing the back of his hand over the plate before collodionising. Crown glass of the usual thickness is unsuited for photographic purposes, beyond the whole plate (8½ by 6½).

(To be continued.)

OUR PHOTOGRAPHIC PIC-NIC, AND HOW WE FARED.

It was arranged to take place in the holiday season just departed to the tomb of its predecessors. The ladies—bless 'em—said it was too early in the season, and their pretty lips pouted at the idea of *photography* in connection with a *pic-nic;* but the gentlemen, like bears, only prepared their dry plates or their dark tents, and discoursed learnedly upon the subject of processes and apparatus the while; and so the fair creatures gave their graceful shoulders the usual shrug of Christian-like resignation; and while pitying the bad taste that could prefer the glare of a photographic lens to the blink of their bonny eyes, determined to show the conceited creatures who fancied themselves so indispensable to make the day pass pleasantly to their fair companions, that the latter could do uncommonly well without them, and, with a merry peal of laughter, the affair was at once definitely settled.

Of course the usual knotty points—the relative advantages of pies, tarts, poultry, joints, &c.—were duly discussed, and finally disposed of.

There came a wet day, and one fair young creature, filled with the spirit of prophecy, said "it [the day in question] was *sure* to be wet." Then came a fine day, and "hope told a flattering tale," while fear was still whispering to the anxious ear, not all unheeded, for April weather was "*so* changeable."

The morn of Friday came — bedrooms were ominously dark. Those eager pleasure-seekers who peeped out saw a sky of whitish drab, gloomily monotonous in its appearance, like some photographs we have seen—a small mist-like rain falling cheerlessly upon the few passengers and vehicles, and not a glimpse of sunlight anywhere.

All met at the appointed place of starting. "How unlucky!" said one. "*I* think it will be fine now!" cried a more hopeful son of the camera. "So do I," echoed another. But the fair prophet looked at the rain, and in a tone of regret, mingled perhaps with some *slight* feeling of pride in the versification of her words, said solemnly, "I told you so;—see what comes of neglect of us!"

We started. A patch of white light stole above the horizon, but our Jehu still expressed foreboding fears. The patch of white light strengthened, widened, lengthened. Into the centre of that pallid patch in the drab-coloured sky came gradually a circular patch more decidedly white: it was—it *was*—THE SUN!

As we travelled on the day brightened gloriously. Shoreditch—with its placarded minor theatres, its costermongers, children of "the peoplesh," penny-show-like photographic *emporiums*, and its varied odours—we left behind. The quietude of Hackney stole upon us, and in its turn gave place to scenes more rural; and soon "the forest" was reached.

We halted, then started off in search of the picturesque, and had not far to go. There were trees with curved and twisted branches, spreading out fantastically. Before was a large pond, with weeds and rushes upon its rippling surface. The long and prickly brambles twisted and twined and drooped about the seemingly dry and withered bushes. Foliage was certainly scarce enough, but the utmost variety of form and texture luxuriously abounded; and *pictures* were seen at every turn of the head, which were as worthy photographing as any the brighter summer or more gorgeous autumn could boast—perhaps more so.

We brought the ladies to the spot, unpacked our apparatus, pitched our tents (dark ones of course), and soon our three-legged, large, cyclopean round-eyed artists reared their bodiless shapes upon the charmingly uneven ground, and to work we went. In a short time numerous plates, both wet and dry, were exposed; of the dry ones nothing can yet be said, but the wet ones all turned out very excellent negatives, as the members of the South London Society will acknowledge, when prints from the same are produced at its next meeting.

We had with us amateur and professional photographers and artists; and when selecting our views or exposing the plates, we did not scruple to throw our individual opinions or experience into a heap, for any member of our little community to pick therefrom as much as he chose or needed. Jokes and fun abounded, although work progressed none the less steadily, until hunger brought both to a pause, and then the hampers were unpacked; and somebody (when taking out the crockery) rashly said something about exposing his plates, and, such is the force of a bad example, somebody else made a joke (?) about their being "dry plates;" while another (desperate offender!) ventured to suggest "coating our plates," and the dry process being a precursor to the wet process; while another culprit asked if champagne were a good *exciting* fluid? and then such a terrible shower of photographic puns fell upon the original offender, that I do think he must be in the agonies of repentance at this very hour.

Occasionally we discovered ourselves to be objects of interest to rustic natives, and some impertinent frogs, and to one timid little dog, the property of a "tired wayfarer;" but no intruders were at all offensive in their remarks or actions, and the meal came to a conclusion amid expressions of general satisfaction. Then we photographed the groups around our dinner cloth, and a charming little picture it has made; then we had more fun, and then we took more pictures. Nothing happened to mar our enjoyment, although we had one negative spoiled by a too—too curious rustic, who went up to a deserted camera in which a plate was undergoing exposure, and, peering in through the lenses, was not discovered until he exclaimed to his companions, in a tone of unqualified delight, "I sees

my hi;" and although one portable camera-stand would obstinately insist upon collapsing at the wrong time, and would not, without much coaxing, condescend to stand firmly; and although one lady of the party did, in her confusion, cross before the just opened lens of the horrified operator, in the fond idea that she was taking precisely the direction he was pointing out instead of that exactly opposite. We duly adjourned for tea, and counted our gains, gloated over our spoils, and reached home after one of the pleasantest day's excursions we have ever known,—the parting wish expressed by all being, "many happy returns of the day!"

Now, this remark (quite applicable, for it is hoped that this will be the birthday of a series of such excursions in connexion with the South London Society) has induced me to pen this brief description of our very pleasant photographic pic-nic, in the hope that I may earn the thanks of many of your readers by pointing out the possibility of so charmingly blending pleasure with purpose.

A. H. W.

[We have a strong suspicion that this is not the first time that cameras have been turned to account to cover a quiet flirtation or two.—Ed.]

ON FIXING POSITIVE PROOFS.

By MM. Davanne and Girard.

(Continued from page 83.)

These observations lead to important results in their application to practical photography, as they point out the cause of the sulphurisation of the proofs. When we take a fresh solution of hypo and wash a print in it, it dissolves a certain quantity of the double hyposulphite of soda and silver; a fresh proof immersed, a fresh quantity of this salt is dissolved; and so on, until the point of saturation (with the double salt) is soon reached, which point is very rapidly attained when we use a solution of ten per cent. From this moment the bath will continue to fix, but being supersaturated with double salt it begins to decompose. If another proof charged with chloride or nitrate is immersed in the hypo, these will act as soluble salts, and will now exercise a slow but sure action on the dissolved double salt. The double salt will be deposited both in the bath and in the paper, then hyposulphite of silver, and finally sulphide of silver and sulphur. The hypo bath will still *fix*, and will do so even until all the sulphur of the hyposulphite has been converted into sulphide of silver; but from the moment it is saturated with the double salt it will produce, both in the bath and on the print, a deposit of sulphurised substances, which will inevitably lead to fading in the proof.

Therefore, without in any way prejudging the practical conditions of the fixing, which will form the subject of a special article, we may say now that the proof, on removal from the pressure-frame, ought, in the first place, to be washed in water, which, removing the free nitrate of silver that would otherwise go into the hypo bath, will thus economise it; also, that the washing of the print in salted water, to convert the nitrate into chloride, is superfluous, because it does not at all diminish the quantity of silver brought in contact with the hypo, and consequently does not delay its saturation; lastly, that the hypo bath ought not to be employed for more than a very limited number of proofs, the number of which will be determined by the strength of the bath, and consequent on the energy of its solvent action on the double salt. We shall recur to this subject when we lay down the practical conditions of a good fixing bath, merely remarking now that, according to our experiments, the double hyposulphite of soda and silver acquires great stability in presence of certain salts, such as nitrate of potash, common salt, &c., which justifies the practice recently proposed of saturating the hypo bath with chloride of sodium.

The second cause of the alteration of the fixing bath, and, as a consequence, of the proofs immersed in it, is due to the addition of certain acids to the bath—acetic acid, for instance. This practice, which was introduced some years ago, is very generally abandoned at present, and therefore calls for no special remark. A fixing bath so prepared according to the reaction—

$$\times\ (d)\quad C_4H_4O_4 + S_2O_2\,NaO = C_4H_3O_3\,NaO + SO_2 + HO + S,$$

necessarily causes a deposit of sulphur on the proofs. This deposit, which forms somewhat slowly, is more or less considerable, according to the quantity of acid added, and the simultaneous presence of sulphur and silver on the print necessarily leads to its fading sooner or later,—therefore this method ought on no account to be followed.

After examining whether the various fixing agents employed in photography left any substance in the proofs capable of influencing their permanence, we next proceeded to examine what action these same fixing agents exercise upon the coloured portions.

In a study of this nature a mere comparison between proofs of various hues is not sufficient; the appreciation is, in fact, too difficult, and rests upon differences too delicate to seize upon. Yet, in simply employing this mode of investigation, we observe certain facts which may furnish some clue.

For instance, we know that by leaving a proof in a strong solution of cyanide of potassium it disappears entirely, in consequence of the whole of the coloured portion being dissolved by the fixing agent. On the other hand, when a proof is immersed in solution of ammonia, we perceive, after it is fixed, that it increases rather than diminishes in intensity; and even if left a long time in contact with this fixing agent, we perceive the *whites* become very palpably tinted. Lastly, if the fixing agent employed be hyposulphite of soda, no apparent change is visible under ordinary circumstances. But these are only uncertain indications, and to throw light on this important question it must be studied from another point of view.

(To be continued.)

NOTICES OF RECENTLY PUBLISHED STEREOGRAPHS.

American Subjects.

E. Anthony, Broadway, New York.

We have been favoured with three specimens of much interest, but of unequal merit. Firstly, there is the Horse Shoe Fall of Niagara: this, though a subject of unparalleled grandeur, is not executed with anything like the skill evinced by Mr. Wilson, of Aberdeen, in the correct illustration of falling water, which in the specimen under consideration looks far too solid. Secondly and thirdly, we have Broadway from Stewart's, Looking South, and Broadway from the American Museum, Looking North. These are two instantaneous views, and here our Scotch friend is certainly distanced. They are bright, clear, and sharp as a needle: even the figures in the immediate foreground, though evidently in active motion, are not blurred in the slightest degree. Both of these specimens are admirable, but the last-named is truly a wonderful production, and no less pleasing than surprising. Hundreds of passengers in every variety of attitude are seen traversing the extensive thoroughfare, with numerous omnibuses, cabs, and other vehicles, in the full blaze of a cloudless sun: the very gait of the pedestrians is distinguishable, and were the individuals depicted personally known to the observer, we have little doubt that they would be perfectly recognisable in the photograph. The whole of the street on the sunny side is lined with sun blinds over the shops, and on the right hand a grove of leafless trees adds to the effect, both by contrast and by the pleasing chequered light caused by the shadows of the branches. This is not a "bit of a picture," but a nearly perfect living reality. Few persons with this slide before them could resist the temptation to purchase, and we feel pretty safe in predicting an extensive demand for it.

NOTES OF A PHOTOGRAPHIC TOUR IN THE HOLY LAND.

No. XV.

We left Nazareth on Thursday morning. Our invalid had revived so much during the early part of the week that it became practicable to effect the removal she so much desired, and we arranged it as well as the rude means at our command would permit. We had to convey an invalid lady about twenty miles across a country in which roads are unknown, and a wheeled vehicle has not been seen since the days of the chariots of Herod.

The conveyance we contrived was a camel litter; but, as we had no camel, we placed it between a couple of donkeys. They are small and hardy, but have an easy gait; and their little feet scarcely rising two inches from the ground, made no jar of the vehicle, but it went even more smoothly than a railway carriage.

We formed a mournful procession too — all on horseback except our invalid. I say *our*. Alas! she is ours now; she belongs to all of us, as all the sainted dead belong to us — dust of our dust, and sharers of our immortality. We rode slowly across the valley, followed by the dark and tender eyes of the Nazareth women, who had learned to love the beautiful Christian girl from far lands, as they had often gazed in on her white face as she lay with the tent curtain thrown back.

Over the wild rocky hills east of Nazareth, covered with a growth of genuine oak, apparently a fine variety of timber, though not large—through wastes on which lilies grow in splendid profusion, down by the western base of Tabor, which is in fact a spur of the last decline of Lebanon, rising into a segment of a circle on

the plain of Esdraelon—then slowly crossing the magnificent upland plain of Galilee, where once the fields of corn grew luxuriant, in which the disciples of the Lord made their Sabbath morning meal, we advanced slowly till sunset, resting frequently. Once a large party of Bedouins met us, but passed on respectfully and in silence when they learned our sad burden. So the evening came upon us, and with it that view which blesses human eyes as no other view of all the scenes this side heaven can bless. The sea of Galilee lay before us, in calm and glorious beauty, far down in its basin of emerald hills.

That night we slept in peace, for the voice of Him who spoke peace to those waters was still sounding over them. Believe me, there is no spot on earth where that voice lingers with such sublime calm as here. All things remember it. The skies re-echo it; the murmur of the waves repeats it; the crumbling walls of old Tiberias seem to hear it. And when the stars are on the sea, and the voice of the winds is hushed, and the low murmur of the ripple forever whispering "Peace! peace!" is the only earthly sound on land or in the air. At such a moment, I say, believe me, there is no other spot of earth so near heaven; no place so fit to die in—so fit to go from into the green fields of the upper country—to pass over to the banks of the still waters.

On Saturday night our invalid began to fail rapidly. None of us slept. It was a warm night—not hot; but a delicious air stole over the sea. The tent door was thrown open, and the side curtains turned back, so that the entire eastern side of her tent was open to the sea. The water of the lake rippled within twenty feet of the canvas, and the old moon, some days past the full, rose at midnight over the hills of Bethulia, shedding a new lustre on the surface of the sea.

To stand on the shores of Genesareth and see one like her depart from the land of His weary footprints into the land of His glory; to witness the accomplishment of the blessing on the pure in heart, uttered by His lips on one of those hill sides, as we saw one of the pure go forth to see God; to see an angel winning at last her wings of light—a seraph gaining at last the perfect tones of the songs of seraphim; to hear again, in tones of melody hitherto but imagined, the voice that sounded of old on the sea of Galilee, "Come unto me and I will give you rest;" to see the sea of life, troubled and sorrowfully clouded, grow calm, as the "Peace, be still!" of His command was audible again above it: all this was ours, but it cannot be yours who read these lines.

When she heard that voice at length bidding her come, there was a radiance on her countenance that made it tenfold more holy than it had always been. She looked out on the sea, and spoke in a few words of her delight at reaching this place to die; and then whispering in her mother's ear words that were meant for no other—words that hum immortal music and comfort to a mother's heart—she turned to all of us and said, "Good bye," as quietly as if she were but going across the water for a day. Then she folded her hands and prayed; and then her lips uttered, in low notes, the words of a hymn we had sung a few days ago: and then she was silent a brief space—and then—and then——

What was it then, oh doubtful, faithless man! who neither in thought nor in the flesh hast followed the footsteps of the Lord—what then? Think you it was a dream, a fancy, a phantasy, that, as we stood there silent and breathless around her couch—father, mother, friends, and servants—we heard a voice from heaven saying, "Blessed are the dead that die in the Lord," and yet another voice, "Blessed are they that mourn, for they shall be comforted."

She lies in the tent yonder, a statue of exceeding beauty. To-morrow we will bury her. The people of the town of Tiberias—Jews, Christians, and Turks—have been very kind, and have offered all the attention their poverty enables them to do. The Jewish Rabbi-in-chief proffered a burial-place among the dead of his kindred; and the Greek priest came after him to say that his people would not object that this our beautiful clay should lie among dust that rested in their faith. But we have chosen a spot on the hill side above the sea, where she can lie and moulder in the dust, for she expressly forbade her parents to move her from holy soil; and here, in the resurrection, among the dead of ancient days, who heard not the voice of the Master when He spoke in earthly tone, reproaching with her holy face the men of Bethsaida and Capernaum, our child will stand up an angel.

I close this my last letter from the East in the saddest yet the holiest evening I ever experienced. I have no heart to pursue my pilgrimage any farther. Bowed down with the weight of grief, I feel the solemn truth of the words of the Preacher, "Vanity of vanities: all is vanity." To-morrow for England and home!

D. T.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

An ordinary general meeting of this society was held on Tuesday, the 3rd inst.,—Roger Fenton, Esq., M.A., in the chair.

The minutes of the last meeting were read and confirmed.

Mr. Malone remarked upon the unexpected conclusion at the last meeting of the discussion upon the collodion report and Mr. Hardwich's paper.

The Chairman suggested that Mr. Malone could give notice of motion to re-open the discussion; and later in the evening the following resolution was moved by Mr. Mayall, seconded by Mr. Malone, and duly put and carried:—"That this meeting recommend the council to re-open the discussion on the Report of the Collodion Committee, and on Mr. Hardwich's paper on collodion, at the next meeting in May, 1860."

Messrs. A. Marion & Co. exhibited two cases for keeping paper a long time after it had been sensitised.

Mr. Shadbolt exhibited an effective arrangement, adapted to one of Melhuish's metal cameras, for exposing and closing two or four lenses simultaneously in the shortest possible time, for instantaneous pictures. He went through a description of the apparatus, which, though simple and easily described with the apparatus in hand, would require diagrams to make our report effective.

The Secretary then proceeded to read Mr. Sutton's

Description of the Panoramic Lens.

I regret that I cannot be present at the discussion on the panoramic lens, but Mr. Cox will show you some apparatus, and explain how to use it.

The No. 2 lens and camera for pictures 7 × 3 can be carried in the coat pocket. The little pictures taken with this instrument and printed upon albumenised paper are very pretty, and the details very fine and elaborate. It is suitable for taking most interesting little views of skies and waves instantaneously with the large stop. Artists who travel for the illustrated journals would find it convenient to use this camera, and take their pictures upon dry collodionised sheets of mica, a hundred of which would occupy but little space in their pocket. I cannot promise that the negatives would be so perfect as those upon glass, but they would be of great use to wood engravers.

The No. 4 apparatus for pictures 15 × 6 is very suitable for amateurs who work with the wet collodion process in a narrow tent. As the curved glasses are expensive, I should advise not to take more than six for an ordinary trip. All negatives which are not absolutely first-rate may be removed from the glass by the following simple process:—Dry and varnish the negative with spirit varnish, then apply to the film a damped sheet of gummed paper. Let this get dry spontaneously, then put it into water and peel it off the glass. In this way you have a paper negative of the subject you wish to preserve, and a clean glass for another attempt. I fancy no one would dream of transposing a first-rate negative.

The best lens for paper pictures is that which I call No. 6. This is 4 inches diameter, and 13 inches focal length. The focus being so long in proportion to its diameter, it will not work so quick as the other lenses. This lens will cover half a sheet of Canson-paper, or even 25 × 10 inches, if the paper is large enough. With a ½-inch central stop it admits a ⅜th-inch pencil upon the front lens. With a high-view lens, 12 inches focus and ⅜ths stop, a paper negative can be taken in full sunshine in three minutes, or less. The time of exposure being the same with the No. 6 panoramic lens, it follows that paper negatives 25 × 10 can be taken in three minutes; that is, in the same time as ordinary paper negatives 8 × 6.

I strongly recommend the No. 6 lens and the paper processes to the notice of amateurs. Hitherto the collodionists have had the laugh against the paper men, but now the paper men can turn the tables upon the collodionists, which the latter are afraid of venturing; even upon a No. 4 panoramic, and contenting themselves with 9 × 7 flat pictures, and an angle of 35°, the paper operators can produce grand panoramic pictures, accounts of which would fill the newspapers next year, while the 9 × 7 bits of collodion would be treated as mere repetitions of what has been done before equally well. The panoramic lens is a grand opportunity for paper work, and it introduces no new difficulties whatever; in fact, the time of exposure is reduced.

In definition and perfect achromatism the panoramic lens is unsurpassed. All along the horizontal line of a view embracing 120° the definition is as good as it is in the centre of the best flat picture. If in any case it should fail at the sides of the picture, that could only be attributed either to an inaccuracy in the radius of the curved glasses or in the centering or mounting of the lens. Such an accident ought never to occur now that we have got things into good working order.

No focussing is required. All objects upon the horizontal line are in focus which are situated between a certain distance from the lens and an infinite distance from it. That certain distance depends upon the focal length of the lens and the size of the stop. If we call that distance the "focal depth of the lens," then the focal depth of the No. 4 lens with a small stop is about 30 feet, and the focal depth of the No. 2 lens 15 feet.

The shorter the focus the greater the focal depth. I have never found the use of focussing in any view-lens, and I worked for two years almost daily without altering the focus of my lens. The smallest stop was the remedy for all optical as well as for some chemical difficulties. If every one agreed with me, and had thought the matter over as much as I have, we should hear no more of the double-bodied sliding and folding view-cameras, or of any of the complicated contrivances for focussing; nothing would be seen out of doors but the single folding camera, which came out soon after the discovery of photography, and the panoramic camera which we are now discussing. My advice is to focus for an extremely distant object in the centre of the picture, and fix the lens at that. If any very near object is refractory, humour it with the smallest stop. An object must be very close indeed if that does not make it sharp with a short-focus lens.

The mode of coating a curved glass 15 × 6 is as follows:—

You hold the glass with its convex side towards you, and begin by pouring the collodion upon one end.

You then gradually elevate the coated end and lower the other, letting the pool of collodion flow towards the middle, until half the plate is coated.

You continue in this way until the whole of the plate is coated, and then you pour off the surplus collodion into the bottle.

In developing the picture you pour on the developer in exactly the same way, only rather quicker, and you let the developer flow backwards and forwards from one end of the glass to the other, until all the details are fully out, and the proper intensity obtained. The left hand should be protected from stains by wearing an india-rubber gauntlet, and a sheet of thin gutta percha should be tied over the sleeve of the left arm.

Any collodion will do in cold weather; but I have no doubt that, when the hot weather comes, alcoholic collodion will be indispensable to success.

In sun-printing the pressure-frame must be turned twice during the exposure, and it is the trouble of doing this which constitutes the chief and, in fact, *only* drawback to panoramic photography. I foresee that, with many persons, this will be a fatal objection, although others may make light of it. He who can get a good negative will probably make little difficulty of the printing.

It is scarcely necessary to say that no one should attempt to work with collodion upon curved glasses unless he is sure that his chemicals are in good order. The object is not to experiment, but to take pictures. Flat plates are better for experiments, because if they get broken there is less harm done. Anxious as I am to see the panoramic lens come into general use, I do not desire to see it at first in any other hands than the most experienced. Until a few first-rate photographers have tried the lens, and expressed their opinion of it and exhibited specimens, I do not care much to see it in the hands of the inexperienced. Better make sure work, and go on slowly at first. But panoramic photography is a new field, in which those who first succeed will carry off the highest prizes.

The Secretary then read a paper from Mr. Sutton *On Panoramic and Plane Perspective*. [See page 109.]

The Chairman called upon Mr. Cox to explain the construction of the camera.

Mr. Cox stated that he had not the slightest idea that he should have been called upon; and although he found that Mr. Sutton had forwarded an intimation to the Society that he (Mr. Cox) would explain the details of the apparatus, he had not forwarded a like intimation to him. He therefore hoped to be excused if his description was not so full and clear as it would have been had he been prepared. He then explained the use of an instrument for holding the bent glass, which was a clamp adapted to the bent form of plate. There was the dark slide of the camera just like an ordinary glass slide, excepting that it was curved in the form of the segment of a circle. There was a pressure-frame which required to be turned occasionally partly round towards the sunlight, but not when printing with diffused light. The camera, with regard to the focussing, was rather in contradiction to the terms of Mr. Sutton's communication. There was a slight focussing arrangement, but which was only a simple convenience to the manufacturer. He found that it was impossible to make a camera so exact that the focus should be true without there was some means of adjusting it. No mechanic could work so closely as to get the correct focus in the first instance, but once obtained, it served for ever. Mr. Cox proceeded to coat one of the bent plates by holding one end of the segment much below the other end, which he held by the left-hand corner; he then poured the collodion along the edge of the lower end, and afterwards gradually reversed the position of the ends, allowing the collodion by its gravitation to flow over the whole plate, until it run off at the other end of the plate, which had thus become the lowest end. He then stated that, after immersion in the curved bath and exposure in the camera, the development would be conducted in precisely the same manner. He then proceeded to describe the camera and lens, and said the focus was seven inches and an eighth, for which the glass was curved. As for an object at 150 feet, he did not find at a distance of 150 feet (and that was as far as in the London atmosphere he had been enabled to obtain a focus) that, with a half-inch aperture, there was any perceptible difference in the focus. Using the three-quarter inch aperture, he did not find any perceptible difference in three-quarters of a mile. He had a lens with a stop giving an aperture of half an inch, and that he found would give a sharp definition at a distance of forty feet, and at a distance of a quarter of a mile. With a half inch stop and $7\frac{1}{8}$-inch focus from forty feet to a quarter of a mile, there was no difference in the focus of the lens. There were two fans placed in front of the central aperture, and the object was to shut out the oblique rays from the central aperture; thus when the light was directly in front of the lens it passed straight through, but when the light was at the side of the lens it went through the side, the fan cutting it off from the centre. If it were merely a circular hole the centre of the picture would receive much more light, and would be solarised before the edge. By using the fan-like stop, whether the principle be right or wrong, the object would be effected.

Mr. Mayall said, they had had a comic English grammar, a comic History of England, and now the photographic world was to be treated with a comic camera — a camera constructed upon principles which utterly ignored all focussing. He did not know whether Mr. Cox's explanation elucidated the subject. At all events, it was but the reproduction of a very old camera, produced in Paris by M. Martin in 1845, and made by Messrs. Schiertz. The difference between M. Martin's camera and the camera of Mr. Sutton was, that M. Martin's was made with an achromatic lens, to be focussed, though not on the usual flat plate. However, M. Martin did succeed tolerably well; and it might be remembered that at that time they had only daguerreotype plates to deal with. He attempted, and in some measure successfully, to make curved plate-holders, to counteract the aberration of his lens. His lens turned on an axis, so as to present the strongest portion of the light to the plate at the different parts; however, it never ended in anything more than some preliminary experiments, worked out by a camera something like the one before the meeting. There was no doubt that for some purposes that camera might be of considerable use, but for the working of collodion on glass it appeared to him to be of very little use to the photographic world, as he did not imagine any extraordinary definition could be obtained with that form of lens. He had not been able quite to follow the Secretary in reading the paper, and he did not know exactly the principle upon which it was founded. At all events, they ought not to ignore the labours of previous discoverers, who had considerably aided the present workers. He saw Mr. Malone was present, and he had no doubt that he might recollect M. Martin's camera. From about 1845 to 1850 M. Martin was engaged with his panoramic camera, and Messrs. Schiertz made it. It was worth while to have *that fact* recorded. Then they had the liquid lenses made by Mr. Archer; and he thought he had had the pleasure of seeing Dr. Diamond working with one, and therefore *that part* of the subject was not new. All that was new was the calculation of curves. He (Mr. Mayall) came to the meeting expecting another kind of subject to be upon the *tapis*, which seemed to be quashed. It appeared to him that there had arisen in this country, as well as in others, since 1851, a system of reproducing the ideas of others; and, while upon the subject, he would mention that there was an invention which went by the name of Woodward's camera. In 1843, while he (Mr. Mayall) was in New York, Mr. Johnson, who was known in this country as a very clever daguerreotypist, bought and sold a reflecting camera, and had at that time a camera almost entirely in construction the same as the Woodward solar camera. He (Mr. Mayall) rose with the desire that some of the early men should not be forgotten in these reproductions; and he thought that the Society should not lend its countenance and influence in putting forward inventions that had been more effectively done years ago.

Mr. Malone was glad Mr. Mayall had spoken first, and he would state that M. Martin's camera gave better results than the one produced to the meeting. Mr. Malone had looked with anxiety at the specimens, because he had noticed the self-sufficient style of the papers put forth by the inventor of the lens, which photographers had better disclaim; for, unless the results produced were better than the present, he could not expect that the Society, or any amateurs of distinction or otherwise, would take up an instrument which, by the results shown, yielded inferior productions. As Mr. Mayall had said, the lens in M. Martin's camera was corrected and arranged for focussing, and here there was no focus. In M. Martin's camera there was a distinct focus to be obtained; and the traversing lens had a peculiar diaphragm arranged behind in the form of a slit, so that as the lens was turned towards one part of the view the image passed through a slit and fell upon that part of the plate which was opposite the slit; then, as the lens turned round, the light impinged upon other parts of the plate, and the first parts were covered up, so that these very ingenious arrangements gave them the means of getting a sharp picture, which certainly appeared to be impossible by Mr. Sutton's arrangement. There is a little ingenuity in Mr. Sutton's arrangement; but the final result is inferior to that obtained by the other method, and for that reason, as practical men, the meeting could not for a moment entertain Mr. Sutton's camera, which was merely an ingenious contrivance that would have been applauded in the first days of photography, but which did not deserve any praise at present — at all events, not that flattering account which the author gave of it.

Mr. Shadbolt came forward in a new character, *i.e.* as a defender of Mr. Sutton—how he might have deserved it was another question. Mr. Shadbolt came forward as defender, because he thought there were quite enough objections inherent in the apparatus before them without attribu-

ting objectionable matters to him which he did not claim. With regard to the matters put forward by Mr. Mayall and Mr. Malone, they were really so extremely prolific in that direction, that it would be difficult to answer them in one evening, therefore he would speak of the lens before them. He regretted especially that so many assertions had been made without any proofs being given. First of all, he took a memorandum of Mr. Sutton's statement, to the effect that focussing with his lens was not necessary. He (Mr. Shadbolt) believed that any one who had paid the slightest attention to optical matters would at once see that the statement of focussing, not being necessary, translated into plain language, meant that he could not focus at all. With regard to Mr. Mayall's observation that no novelty was produced, he thought that was an error into which Mr. Mayall had fallen, from not having examined the lens. It was dependent upon this principle that a sphere of glass containing a sphere of distilled water should be so arranged that the two combined should be achromatised, and that, consequently, for a spherical surface, and for a spherical surface only, it would have a focus for a distant object—an absolute solar focus for objects at a long distance. Now, unfortunately, as the bulk of objects photographers had to delineate did not stand at so long a distance, the bulk of terrestial objects were absolutely out of focus. But, again, it must be remarked that they had not in Mr. Sutton's case a sphere but part of a cylinder to work upon. The remarks made about ignoring focussing altogether resolved themselves into the self-evident fact, that the camera was not adapted for it. He very much regretted that the matter had not been made more tangible than it appeared, for he confessed that, two years since, he believed a panoramic camera a possibility, in consequence of having seen that very camera of M. Martin's. The gentlemen stated that it was owing to the perfection of the lens that M. Martin was enabled to get a comparatively sharp picture; but he (Mr. Shadbolt) thought that that was an error, and that Mr. Sutton's camera would produce a picture as sharp as that of M. Martin's, provided the plate was arranged in the same way. M. Martin's did not describe a part of a circle, though a curve, but had an adjustment by which he could accommodate the daguerreotype plate to the focus of the object immediately under inspection at the moment: he had a means of arrangement by which a part of the plate should be a little nearer or distant from the lens, and it was in consequence of that that he was enabled to get a something approximating to a sharp picture all over. He (Mr. Shadbolt) took some pains to examine the negative from which the picture before the meeting was produced. The negative was in Mr. Cox's shop.

Mr. Cox explained that that was another negative of the same subject.

Mr. Shadbolt stated that, on examining that negative, he was prepared, and expected, and hoped to be able to admit that it afforded a tolerably sharp picture; but, so far from that being the case, he only found about one-third tolerably sharp, and two sides of the picture absolutely out of focus. There was absolutely no correction for spherical aberration, with the single exception of reducing the aperture. The stop which had been exhibited was both a novelty and highly ingenious, and did certainly so adjust the light that the oblique rays were equal to the direct rays. Although Mr. Mayall had stated that there was nothing new, that was something which had really never before been brought before the public; and he thought that Mr. Mayall would, upon examination, absolutely admit that the lens was new. But then the question was not only as to its novelty, but also as to its applicability. With regard to some of the objections to the camera, they must not criticise too closely the assertions made by Mr. Sutton, who evidently was not a man who looked with an eye too unfavourably towards his own project; and although he did occasionally, and perhaps unconsciously, use hyperbolical language, and said that pictures delineated upon flat surfaces produced hideous caricatures, and then went on to argue that, to take a panoramic perspective, you must take it upon a curved surface, yet how did he prove that? He says that, on taking a row of houses exactly identical with each other, but in the form of a crescent—taking them in his camera, afterwards printing them, and spreading the print out flat, it would be mistaken for a straight-built row of houses. Now, *entre eux*, he (Mr. Shadbolt) believed Mr. Sutton had actually found that out from an article in The British Journal of Photography, written by Mr. Grubb, in which he pointed that out, and more than that, viz., that in taking a picture of a long row of flat houses, by means of a panoramic lens, you would have a plate, when opened out, with all the horizontal lines curved towards the extremities. It was quite clear that if they observed horizontal buildings they did not see curved lines, but absolutely straight ones—that could not be questioned; so, under the circumstances, Mr. Sutton said that before he could tell what he had got he wanted to inquire what lens it was taken by, which reminded him (Mr. Shadbolt) of the schoolboy who delineated something upon his slate, and wrote beneath that something "this is a house." With regard to the objections to the use of the lens, he thought the curved glass was its greatest drawback, as it could not always be obtained with the exact curve. With regard to the manipulatory details they might be more troublesome, but if they produced better results there were plenty of resolute men who would successfully grapple with all manipulatory difficulties. He thought it did not succeed so well as the ordinary camera, especially in the focussing.

Mr. Malone thought Mr. Shadbolt was as facetious as the author of the paper, and that he gave up the points which he rose to defend. M. Martin's camera had at the back of the plate-holder a series of screws by which he could adjust, almost at will, the daguerreotype plate, and focussing with a slip of glass, and then putting the screws against the glass in such a manner that he was sure he had got the focus of one portion of the segment, he then went on to the next segment, and so he insured a focus which Mr. Sutton's utterly failed to get. He admitted the novelty in the diaphragm, and gave great praise to it, but Martin's arrangement was better.

Mr. Heath stated that he had but a very few remarks to make, simply because he so completely and entirely coincided with the opinions expressed by the previous speakers. With Mr. Shadbolt himself he entirely agreed, not only in his present remarks, but in those expressed in the March number of the British Journal of Photography. He could not help acknowledging the impartial manner in which Mr. Shadbolt had discussed this question, and he (Mr. Heath) only wished that every one present would be equally judicious. Mr. Shadbolt was an old member of the society, and his opinions were very much esteemed. With respect to the camera he (Mr. Heath) really did not see any advantage at all; and, looking at the curved glasses for the image, the curved printing frame, and he was "going" to say the roundabout way of accomplishing that which was best accomplished in the straightforward way (and which was the better way in all matters of life), he had looked at all these matters as decided disadvantages. Looking at the pictures exhibited, looking at the negative at the last meeting, and recollecting Mr. Sutton's trumpet notes heralding his production, he (Mr. Heath) was much struck with the complete want of definition. That Mr. Sutton had produced an ingenious thing was beyond all question, but no person could venture for a moment to compare it for efficiency with the ordinary productions.

Mr. Hughes observed that there was one peculiarity of the camera which appeared to have escaped the notice of the gentlemen who had spoken of it. In testing its capabilities one should put it through the various positions in which it was likely to be used. Landscapes were not invariably taken with a view to lateral effect, and lateral effect was the sole point for which Mr. Sutton intended the large angle of vision; but in practice there was as much vertical as lateral effect requisite, and how was he to treat that camera with reference to vertical effect? If Mr. Sutton had abandoned the portion of a cylinder, and made his plate hemispherical, he would have been consistent. Supposing he had to take a church with a spire, probably the camera would be turned up at right angles to its usual position, then what sort of a picture would be obtained? and yet without that, which was the only way of getting over the difficulty, the spire would be *in nubibus*. Mr. Shadbolt had stated that if the results were superior to those usually produced, the manipulatory details would be got over; but looking at the pictures produced he (Mr. Hughes) thought it very difficult to come to the conclusion that they ever could be superior—at present they were decidedly inferior. There was none of that two-eyed effect, having a large angle of vision. Purposely waiving the point as to the superior definition altogether, he remarked that they had had the curiosities of literature, the curiosities of science, and when the curiosities of photography came to be considered, that camera must occupy a very distinguished place.

Mr. Le Neve Foster had looked at the pictures and ascertained the remarkable want of definition, although Mr. Sutton appeared to think that there was a great deal of definition. He (Mr. Le Neve Foster) found Mr. Sutton writing in his paper these words:—"*I have never found the use of focussing in any view lens*"—which passage was incomprehensible. Mr. Sutton also said, "and I have worked for two years almost daily without altering the focus of my view lens."

Mr. Sebastian Davis thought Mr. Sutton must have meant his own lens. As far as focussing went his lens would not admit of focussing, for it was supposed to take a picture from a mathematical point in the centre of his view, and to describe a circle round; and it was quite clear if he (Mr. S. Davis) took a given point as a centre, and described a circle around it, focussing would be out of the question, as also if Mr. Hughes's idea of the adoption of a plate of a hemispherical form were to be carried out.

Mr. Mayall believed Sir William Newton was not present, but that picture entirely coincided with Sir William's conditions. He (Mr. Mayall) had not a doubt that, artistically speaking, apart from photography altogether, the picture exhibited was extremely artistic, the lens appeared to be an imitation of the human eye as far as he could see at the present moment; but the discussion about the lens had not put it in any better position. It would only serve the conditions of those artists who said that there was nothing artistic in photography; and let such an artist purchase one of those pictures, and he would find that he had his ideas wrought out. If they fixed their eye on any single object in the room, that object would be seen with distinctness, but every object around would gradually shade off; therefore all the value of the camera was to gratify those gentlemen who, up to the present time, did not admire sharp pictures, but who, like their distinguished member, Sir William Newton, were very fond of having only the central point sharp.

Mr. Eliot did not know whether Mr. Sutton's other lens was in the room, the triplet, which was experimented upon by Messrs. Ross some years ago, and proved by them to be a total failure.

Mr. Cox thought there was some misunderstanding when gentlemen stated that there was no focus at all; for it would be remembered that be had stated that at a distance of about thirty or forty feet to about a quarter-of-a-mile there was no preceptible difference in the focus, and it could not be denied, if they took the cottage in a picture he then produced, that

that cottage was sharp, and the distant object was sharp, or he did not know what sharpness meant. It would be understood that the picture was a developed print—not an albumenised picture. If they altered the focus of the lens nothing would be sharp, because it acted upon the principle that from the centre of the lens to the centre of the plate must be a given distance. The pictures then in the hands of the Chairman proved what the lens would do. The first one was taken in Christmas week, which was not precisely the weather for photography.

Mr. Malone stated that it was not usual to reply upon the final speaker to a question, but when he produced another picture and argued upon it, he must ask to see it, and after seeing it he must be permitted to state that there was a point in it of greater sharpness in the centre than the others; but he maintained that the greater part of the picture was absolutely without definition, and the real question was, not whether any one point was defined, but whether the whole picture was good? The consequence was that the picture, taken as a whole, was a failure, and a decided failure as compared with Martin's productions.

The Secretary then read a paper by Mr. J. Wyard, *On the Production of Photographic Pictures on Glass or Porcelain, by enabling them to be burned in*—of which we give the following abstract:—The author effects his object by covering the porcelain or glass plate, first slightly warmed, with a solution of gelatine, gum arabic, and bichromate of potash, to which are added a few drops of honey syrup. The film is dried by the fire, and exposed to the light under a positive photograph for a few minutes in good sunshine. The ceramic colour, finely ground, is then applied to the surface of the film by means of a cotton pad, when it will be found that colour will adhere only to the unsunned parts of the film, forming on it a positive representation of the photograph to be copied. The film is then washed with alcohol, to which a small quantity of dilute nitric acid has been added, and when the brown colour of the changed or sunned portion of the bichromate film disappears, the plate is washed with pure alcohol and dried rapidly. A flux is then applied as follows:—A solution of Canada balsam in spirits of turpentine is poured over the plate, which is then dried by heat, and the flux, consisting of borax and glass, or borax, glass, and lead ground fine with water on a slab and dried, is applied evenly by means of a cotton pad tied up in very soft and flexible leather. The plate should be glazed prior to the application of the film.*

Mr. Mayall thought he could add some information upon the subject, having been engaged in about 1850 upon the subject of transfer. After the collodion was invented he went to see his friend Dr. Diamond, who was at that time developing his pictures with the protonitrate of iron producing great metallic lustre, and the idea struck him (Mr. Mayall) that if they could be transferred to cameos in some simple manner they would be extremely valuable. He set to work to try to transfer them to porcelain or glass. He took some twelve or fourteen portraits of various sizes; he washed over the surface of the collodion with a weak solution of gum, and then pressed down the enamelled glass upon the gum, and let them stay in contact for a short time He then dragged the two apart, and in that way transferred the collodion to the piece of glass which had been made expressly for the purpose, so that with a very slight heating in the muffle-furnace it would melt in. He then placed a very thin film of microscopical glass upon it, and passed it into the muffle-furnace: sometimes it melted the whole thing down into the glass, and sometimes he lost the image entirely, but when the process was carefully done the image of the photograph was melted in between the very thin glass over it and the very soft ductile glass under it, and was thus rendered impervious to the atmosphere and to scratching. He knew that there were now in the possession of Her Majesty a number of pictures that he did at that time. Then a M. Andrew Bulot having heard that he had done a number of things, came over from Paris and waited upon him (Mr. Mayall), who had been trying experiments with collodion excited by the iodide and bromide of cadmium. He (Mr. Mayall) also had an interview in London with Mr. Minton, of the Potteries, on the subject, with the intention of transferring copies of the old masters to vases, and to plates, and a number of things of that kind: however they were very busy, and he (Mr. Mayall) was similarly situated, and it came to nothing. He believed M. Andrew Bulot took out a patent for a process which he introduced into this country, but he was obliged to make some arrangement with him (Mr. Mayall), as he had done the same thing before, and he was to have had some benefit; but he knew that, after he had advanced a considerable sum of money, the party disappeared and the process with it, and there was an end of the matter. It was quite as well that it should be known that processes of that kind were to be done, and it was astonishing what an extraordinary heat even positive collodion would stand in the ordinary muffle-furnace, and if it were covered with a thin glass, containing a large amount of lead, an ordinary photograph would produce almost the appearance of enamel. He was quite sure there was great value in the process, and hoped some gentleman would carry it out. He thought M. Bulot's patent was dated in 1851 or 1852. If he had been aware of the paper being read he would have brought a handful of specimens.

M. Joubert had listened with great pleasure. He was now engaged upon a patent process for burning photographs in glass and china in colours. Mr. Mayall's statements were interesting, but they only related to one colour. M. Bulot's patent could not come to any good, because he had not found out the means of applying different colours, which of course could only be obtained by processes different from the collodion process. His own process was only recently patented, and not specified, therefore he would be excused if he did not divulge it; but he would say that he did not use any collodion at all—it was a very different mode altogether: it was, as it were, grafted upon another process. He was under a promise to the society which, he regretted to say, had not yet been fulfilled, of presenting to the society a number of specimens. There had been some difficulty in the mechanical part of the manipulation which had been kindly alluded to in the last number of the Journal; but he had done some even that very day, and had been engaged upon it constantly. He had been in great hopes that they would have been presented in April, but he would confidently say that they should be presented in May. He (M. Joubert) then exhibited two specimens of his new process, which were very beautifully burned in without any glass above the surface.

Mr. Mayall had forgotten to say, that not only did he produce them with a variety of colours, but with a variety of backgrounds. An ordinary photograph fixed upon a rich ruby glass gave a very beautiful effect. He ground some specimens of twelve or fourteen kinds of coloured glass into impalpable powder; and with the impalpable colour they coloured the portraits, and then put the thin film upon them, and passed them into the furnace. Very extraordinary results were obtained; for in some cases where the cheeks were put in red they came out green, and in other cases blue, by some strange property in the silicate. It was extremely uncertain whether a lady painted in most beautifully did not come out a greenamoor or a blackamoor, though it did sometimes happen that the ground glass came out the same colours as were put in. If any gentleman of sufficient standing as a scientific man would seriously take up the subject, he (Mr. Mayall) would give him a drawerfull of results to assist him. There was something more in it than was at present fancied, and there was no doubt the silicates of some of the metals must be used in the shape of pigments, and perhaps they ought to be slightly more fusible than the glass itself. Without knowing anything of M. Joubert's process, he would suggest the use of the more easily fused silicates for the higher lights, the less fusible for the middle tints, and still less fusible for shadows. He was very glad that something had come before the society. Gentlemen must be very careful in steering clear of a patent already in existence, although he (Mr. Mayall) thought M. Bulot's had about expired. By using silicates for pigments a variety of colours would be produced, highly interesting to ceramic art.

Mr. Malone asked Mr. Mayall to pardon him for reminding that gentleman that he (Mr. Malone) was the first person that ever attempted to burn photographs into materials.

Mr. Mayall begged Mr. Malone's pardon, and recollected seeing his specification.

Mr. Malone stated, with regard to heating a picture, that it was found that silver pictures, when in contact with substances with which they combined, gave a faint or feeble picture. It was also very clear that, if chromium, and things of that kind, were used, instead of silver, there would be no difficulty in procuring an intense picture. His object had been to make negatives upon porcelain; and it would be seen that, if it could be done upon porcelain, it could be done more easily upon glass, because in that there was a silicate of potash, more easily combined. If a salt of chromium were used, instead of a salt of silver, a red picture would be produced; but nobody would look at their portrait entirely in red: moreover, the portraits of chromium did not yield equal delicacy with that of the silver process. Long since pictures by means of chromium salts had been produced in Paris. His experiments were interrupted by not being able to get porcelain in thin slabs. He spent some days at Mr. Minton's, vainly endeavouring to get him to procure some thin slabs of porcelain by means of his hydraulic pressing apparatus. Mr. Minton was so busy at the time, making the compressed tiles, that he could not take the matter up, saying he did not think it was feasible, and endeavoured to discourage him; but he (Mr. Malone) did not give it up, but went, after the exhibition of 1851, to Sevres, and, strange enough, there met Mr. Minton, who recognised him. Mr. Minton, guessing the object of his visit, said:—"Oh! Mr. Malone wants to burn photographic portraits on porcelain, but it cannot be done." Mons. Ebelmen had previously privately said it could, and offered to place the Government establishment of Sevres at his disposal. He mentioned this to show that there was something to be done. If it were asked why it was not done, it would have to be remembered that about that time there were political changes in France, and that both Mons. Ebelmen and Mr. Minton had died since then, and that was the reason the experiments had ceased. The first thing was to procure the biscuit porcelain translucent, and yet retaining porosity, so that a metallic solution could penetrate it, destroy the albumen, or whatever else it was put in with, and then oxidate it. The silver picture was so faint, that recourse must be had to chromium and manganese, and then the picture was not so delicate; still it was quite clear that good pictures could be at once burnt into thin slabs of porcelain. His proposition was to take a solid slab of perfectly homogeneous porcelain, and then to saw that slab through. M. Ebelmen said *it was* practical, Mr. Minton said *it was not*—that it would be full of holes and other imperfections; and so it was—at least that which was made

* We would draw the attention of those of our readers who have an opportunity of visiting the rooms of the Society of Arts, Adelphi, London, to specimens of the processes of Mr. Wyard and M. Joubert, now on view at the society's exhibition, being numbers 144 and 143 in the catalogue. Judging from the large enamel of *The Head of Our Saviour*, we should say that M. Joubert was far in advance of Mr. Wyard in the perfection of his manipulation.—Ed.

in this country. As Mr. Mayall was anxious that merit should go where it was due, he (Mr. Malone), when seeking for a small share, could not be asking for too much.

M. Joubert remarked that what had been said by Mr. Mayall and Mr. Malone only showed that for a number of years attempts had been made to transfer photographs, but that no one had ever taken up the subject of treating them in different colours, except that which the medium on which the photograph was made could produce, and for the reason, that it was only recently that the means had been found of using any given colour, and in that was the very medium for which he had taken out his patent: it was for transferring them in any colour, or with two or three colours in any picture, which no photographer had attempted to do. The process which Mr. Mayall had described could only produce one colour, and that the colour of the photograph.

A Member: Mr. Malone said it was necessary to have tiles of that very complicated manufacture. He (the speaker) had had the pleasure of seeing lately very beautiful specimens of M. Joubert's burned into the common glazed Minton tile, quite perfect in form and colour, in red, yellow, brown, green, and indeed there was no limit to the colour, which was the great desideratum of the present day. The burning was perfectly genuine, and there was no attempt at putting a film upon it.

Mr. Malone said that he was then speaking of translucent tiles, while the last speaker was alluding only to opaque tiles.

The Chairman read a paper which had been placed in his hands, which stated that Mr. Davenport was the first who proposed the use of porcelain instead of paper, and for which he procured a premium in 1849 from the Society of Arts.

Mr. Davenport rose and stated that the circumstances under which it occurred would probably be brought to Mr. Malone's memory, by the fact that in about 1849 he was making experiments in the manufacture of paper—he believed at Maidstone—with a view to getting rid of the irregularities of the surface of the paper used for the Talbotype process. At that time Mr. Davenport and Mr. Malone frequently met at the Society of Arts, where were being held exhibitions of manufactured articles. Among the articles exhibited were a number of beautiful biscuit figures in china or porcelain. It occurred to Mr. Davenport that if the biscuit body could absorb a certain portion of chemicals, a perfectly flat surface would be obtained to print through; and Mr. Malone would remember that, conjointly with him, they drew up a paper, which was recorded at the Society of Arts. Mr. Davenport did not wish in any way to detract from Mr. Malone's experiments.

Mr. Malone said that, after the direct appeal to his memory, he must say that he had completely forgotten any such circumstance, though if Mr. Davenport's memory were correct, still he (Mr. Malone) was the first who attempted to carry it out. He by no means contradicted Mr. Davenport without looking at memoranda and dates, but there was the fact that no one had done anything of the sort, or proposed anything of the sort previously.

Mr. Manley exhibited an extraordinary expanding camera, which he called a telescopic camera, in consequence of the range and manner in which it could be extended by draw-tube compartments. It was intended for long or very short focus lenses, and for copying. The arrangement by which the various compartments were brought into action, and focussed by aid of an endless screw, was very ingenious. A novel feature, and of general applicability, was the disposition of the focussing screen. Instead of sliding into a vertical groove as usual, it was drawn forth from a horizontal receptacle in the roof of the camera, and then by a hinged motion lowered into its proper position, without being detached from the instrument, where it was fixed by a spring. When done with it was returned to its compartment, and was thus always out of the way and out of danger when not in use for focussing.

The thanks of the society were tendered to the several gentlemen who had brought papers or objects before the meeting; and the Chairman announced that the next meeting would be held at their new apartments in King's College, on which occasion it was expected the President would take the chair.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

The usual meeting of this Society was held in George Street Hall, Edinburgh, on the evening of the 10th instant. Sir David Brewster, President of the Society, occupied the chair.

The minutes of former meeting having been read and approved of, the Viscount Strathallan, Strathallan Castle, Auchterarder, was admitted by ballot as an ordinary member of the Society.

The President then read a *Notice respecting the Invention of the Stereoscope in the Sixteenth Century, and of Binocular Drawings by Jacopo Chimenti, da Empoli, a Florentine Artist.*

Sir David having had occasion to inquire into the history of the Stereoscope, found that its fundamental principles were well known to Euclid, Galen, Baptista Porta, and others. B. Porta, in 1599, gave a complete drawing of two separate figures as seen by each eye, and of the combined picture placed between them. Hence not only the principle, but the construction of the stereoscope was here recognised. Still, however, there was no proof that any person had drawn a right and left eye picture of any object and united them either by the eyes or by an instrument; and it was scarcely to be expected that any such discovery could be made. Last summer, however, when Mr. Alexander Brown, with his brother Dr. John Brown, was visiting the Musée Wicar, at Lille, the former gentleman observed two water-coloured drawings placed side by side, and so perfectly similar that he could account for the fact only by supposing them to be binocular pictures, intended to be combined into relief either by squinting with the eyes or by an instrument. The size of these pictures was about twelve inches by eight and half inches. They were executed by Jacopo Chimenti, da Empoli, a painter of the Florentine School, who was born in 1554 and died in 1640. They represented the same object from a slightly different point of view. The subject was a young man sitting on a bank, and Mr. Brown saw it to most advantage at a distance of four or five yards. By the usual mode of looking at stereoscopic pictures without an instrument, Mr. Brown succeeded in getting the two pictures to coalesce, when they formed one picture in perfect relief.

Sir David concluded by stating that he had some correspondence with a view to getting photographs taken of these interesting pictures, but that at present there were some difficulties in the way of accomplishing this which might eventually be overcome.

The Chairman then read a letter which he had received from Mr. Skaife, respecting the "Pistolgrams" exhibited at the last meeting.

Mr. Tunny said that it would be in the recollection of those who were present at the last meeting, that his observations at that time had no reference to the merit of Mr. Skaife's invention. When Sir D. Brewster, on that occasion, presented Mr. Skaife's specimens to the members, Mr. Tunny understood him to have said that they were preserved from damp or other atmospheric influences by enamel, and, upon examining them, he (Mr. Tunny) had stated that the appearance of the specimens did not warrant him in supposing them to be protected by enamel or homogeneously combined, but that the two plates of glass rather seemed to be cemented together by some cement holding together the edges of the glass from which the collodion had been removed, and he had proved this at the time by separating the two glasses. Mr. Skaife had not relished the liberty Mr. Tunny took with his pistolgrams, and, as most present would be aware, had written (in anything but a good spirit) to one of the Edinburgh daily papers, the *Caledonian Mercury*, denying the correctness of Mr. Tunny's surmises. As he had made his observations at the last meeting he waited till the present meeting to reply to that letter, which he would do as follows:—Having procured from England some of Mr. Skaife's pictures he would immerse one of them for a short time in a small bottle of benzole, which he had brought with him, when he expected that in a few minutes he would be enabled to show them the glasses separated without having this time recourse to his knife.

[Later in the evening Mr. Tunny removed the specimen from the benzole, when the cement was so soft as to enable him to separate the glass cover from the picture, in which state it was handed round the room.]

A paper was then read from the Rev. T. M. Raven. It was designated, *On the Preparation of Paper for the Waxed-Paper Process, with some Remarks on the Effects Produced on Sensitised Positive Paper by Contact with Papers which have been Exposed to Light.*

The chief topics embraced by Mr. Raven's paper, in addition to the above, were gutta percha as a material for making baths, dishes, &c., for photographic purposes; lenses for views, &c.; although a variety of other subjects were introduced. He had been a good deal engaged in testing lenses for some time past, with a view to obtain one for his own use. He had a very good orthographic lens by Ross, which he had had corrected by Mr. Ross shortly before his death; but to beginners he would recommend a good lens of the ordinary meniscus form. He had for a few days last summer been trying collodion instead of waxed-paper, and used Smartt's tent, which he could recommend, as it was easily put up and taken down. A great deal more could be done with waxed-paper than was usually supposed, and for out-of-door purposes it had greater advantages than most other processes. In the waxed-paper process most operators used too much acetic acid. He detailed the mode of preparing paper and operating which he employed at present, the most important feature of which was that he found it expedient to discard the use of gutta percha baths in the whole of the operations connected with this process. In the common sheet gutta percha of the shops, small red spots might be seen. These Mr. Raven had often found transferred to the picture. He preferred *glass* dishes and baths. With respect to the exposure, he was understood to say that, in his experience, the farther he went south, the longer was the exposure required. It was his intention to publish a manual of the waxed-paper process; but those desirous of practising it would find ample directions in the back numbers of The British Journal of Photography. He concluded by some remarks on the new action of light recently noticed and commented on by Niépce de St. Victor, but on which nothing new was elicited.

Mr. Horatio Ross said that, when he was recently at Hythe, he had the good fortune to meet with Mr. Roger Fenton, and some conversation he had with him induced him at this time to make one or two remarks. He might begin by stating that Mr. Fenton was just as good a rifle-shot as he was a photographer, and that was saying a good deal. On telling Mr. Fenton that he found gutta percha discolour his nitrate of silver, he was told by him that he (Mr. Fenton) had kept his bath in gutta percha for five or six years; but it took him several weeks to prepare the gutta percha bath for this purpose. He had, first of all, kept it full of water for a fortnight; then he had filled it with a solution of cyanide of potassium;

then with nitric acid and water mixed, and, lastly, by a copious washing with water — and by this treatment he had kept his silver in good order for several years. Now and then he pours out his bath, and, by mixing whiting with it, makes it neutral; and then gives it the desirable faintly-acid tinge, by adding to it some fresh nitrate of silver. He had seen Mr. Fenton operate, and nothing could be neater.

Mr. Moffat had found glass baths for nitrate of silver to answer much better than gutta percha ones, although the latter, from their comparative lightness, might be better adapted for a travelling photographer.

Mr. Finlay Anderson remarked that Mr. Raven seemed to have changed his views, as it was not much above a year since he (Mr. Raven) had recommended to him a gutta-percha bath, with a piece of glass laid on the bottom.

Sheriff Moir and Mr. Taylor made some remarks on the greater length of time required to expose a photograph in Africa compared with this country; after which,

Mr. Finlay Anderson read a short paper *On Photographic Landscapes*. He complained that a disagreeable, ill-balanced effect was observable in many pictures of this class, owing to there being too much foreground and too little sky introduced. The remedy of this was very obvious. The sky line he thought should, in most cases, be a little below the centre of the picture.

Sir D. Brewster spoke of the advantages to the photographer of an erecting camera, in which the picture might be seen exactly as in nature, and not upside down, as in the ordinary camera.

After an intimation by Mr. Horatio Ross that he had a paper, written by Mr. Claudet, to read at the next meeting of the society, the meeting separated.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this society was held on Wednesday, the 4th instant, at the rooms of the Literary and Philosophical Society, 36, George Street,—W. C. Williamson, Esq., presiding.

Mr. E. Mann, the Hon. Sec., called the attention of the members to the subject of the album which had been purchased for the purpose of inserting the portraits of the members of the society, and which it was thought would form a very important and interesting record, and said the council of the society regretted very much that the members were so slow in contributing portraits. He had, however, now the pleasure of stating that Mr. A. Brothers had contributed a very excellent portrait of the Lord Bishop, the president of the society, which was handed round to the members, and very much admired; and he hoped that, as a commencement was made, the members would have less hesitation in making their contributions to the album. The Secretary also handed to the members a stereoscopic instantaneous picture, which Mr. Brothers had brought to show to the meeting.

Mr. Brothers said he had purchased it because he considered it the most wonderful instantaneous picture he had seen. The subject was some steamers on an American river, taken whilst moving at great speed.

The Secretary mentioned that the proposed exchange club was progressing very favourably. He had now obtained fourteen names, and it was proposed as soon as the number amounted to twenty to form a committee to carry it out, and he should therefore be glad to receive further names.

Mr. W. T. Mabley then read a paper *On Photographic Printing upon Paper*. [See page 110.]

Mr. Wardley moved a vote of thanks to Mr. Mabley for the paper he had read, which was seconded by Mr. Parry. He (Mr. Wardley) said he thought the way in which Mr. Mabley had treated the subject was most excellent, and that the numerous experimental illustrations were most valuable.

The Chairman said he was sure the very best thanks of the society were due to Mr. Mabley for his paper. He considered Mr. Mabley had adopted the only true plan by investigating into the very foundation of the process; and that if the photographers of the society would conduct their experiments on a similar plan, the Manchester Photographic Society would be second to none.

The best thanks of the meeting were unanimously accorded to Mr. Mabley by acclamation.

Mr. Parry said he should be glad to suggest (if Mr. Mabley was willing) that he should present his experimental illustrations to the society's portfolio, as they would form a very valuable record.

Mr. Mabley said he would be very happy to accede to the request.

Mr. Offer said he should be delighted to hear a promise from Mr. Mabley that he would at some future meeting continue the subject of the printing process, which he had so ably commenced.

Mr. Mabley said such was his intention, and he should be most happy to do so. In preparing his paper he had found it quite impossible to deal with the whole subject in one evening; and he had first confined himself to the silver sensitising bath, and would treat of the gold toning bath on the next occasion.

Mr. Wardley remarked that he had not found that paper sensitised and kept some time was any more difficult to tone in consequence.

Mr. Brothers remarked that he was troubled with the removal of the albumen, by using the alkaline gold for toning.

Several of the members thought that if the silver was strong enough such would not be the case.

Mr. Brothers said Mr. Mabley had mentioned a printing frame which he had used, having no plate glass before the negative, and asked to see it. It was handed to him by Mr. Mabley; but it was thought to be unsuitable for large negatives, as sufficient pressure could not be used.

Mr. Mabley said he always used a piece of thick flannel in the printing frame, and found it very excellent in producing an equal contact with the negative.

Mr. Wardley exhibited some excellent prints, taken by a bath four years old, and which had been in constant use for negatives, &c., and no doubt contained many impurities: this showed that almost any kind of bath containing sufficient silver would do for printing on paper.

Mr. Parry exhibited a remarkably compact stereoscopic camera, constructed by himself, which was thought to be the most portable thing the members had ever seen. It would go quite flat, was very light, and might be put into the pocket. He also exhibited a very convenient bag or hood for changing plates, having a small board at the bottom, forming a table on which to rest the plate-box, and which Mr. Parry said he found particularly useful.

After a vote of thanks to the Chairman, which was passed by acclamation, the meeting closed at a later hour than usual.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

The annual meeting of the above Association was held at the Chorlton Town Hall, on the 11th instant,—Mr. John Fawcett in the chair.

After the minutes of the last meeting were read and confirmed, the following gentlemen were elected as officers for the present year:—

President—Professor Roscoe.
Vice-Presidents { Mr. J. H. Nicholson. / „ William Griffiths.
Treasurer—Mr. William Hooper.
Hon. Secretary—Mr. John Heywood.

Council.

Mr. John Rogerson,	Mr. John Fawcett,
„ Thos. S. Sheard,	„ E. Whaite,
„ G. Wardley,	„ C. Aden.

The Secretary then read the following Annual Report of the retiring council:—

ANNUAL REPORT.

In presenting their report of the third year's proceedings of the society as required by the rules, the council feel that few incidents have occurred during the past year that offer subjects for special comment. The general attendance at the meetings has been about equal to that of last year.

Papers have been contributed by —
Mr. Draffin — *On Comparative Experiments on several Dry Processes.*
Mr. Heywood — *On Toning Positive Prints.*
Mr. Hooper —*On the Camphine Waxed-Paper Process.*
Mr. Griffiths — *On Enlarging Glass Negatives.*

The paper of the first-named gentleman, formerly secretary to the society, but now residing at a distance, was accompanied by several specimens, which he kindly allowed to be disposed of for the benefit of the society. All the papers gave rise to interesting discussions, which, it is hoped, would not be without profit to the members.

The number of papers read during the past year have not been numerous. The council lament that such contributions to the common fund of instruction and entertainment should be confined to a very few of their members; and they would urge on those who have hitherto hidden their light under a bushel, to lend their aid, as far as possible, in making the society a useful centre for the diffusion of photographic knowledge.

No very scientific and learned theories or investigations are asked for or expected; but if members would make a note of any of those unlooked-for results which are constantly occurring in the practice of our art, and communicate them to the society, they would add much to the interest of the meetings, and often be the means of leading others to institute experiments which might lead to important results.

In the chief end, however, which the society has in view, the council confidently trust that their association is fulfilling its mission, and rendering itself worthy of support: as offering facilities for interchange of opinion — of mutual help — of social intercourse, and the formation of friendships, cemented by an ardent devotion to a fascinating and refining pursuit.

It was carried unanimously, that the report now read be received, and entered in the minute book.

A vote of thanks was passed unanimously to the President, Vice-President, Treasurer, Secretary, and the Council, for their attention and devotedness to the interests of the Society.

The Chairman, in putting this, remarked that, from the very small subscription—only five shillings per annum—there must be economy used to bring the financial affairs of the Society to the present position. He noticed the treasurer had a small balance in hand, which he had not expected.

Mr. Pershouse and Mr. Nimmo were elected members of the Society.

Mr. W. Griffiths then read a paper *On a New Dry Collodion Process*. [See page 111.]

Mr. Hooper exhibited a waxed-paper negative, prepared by a gentleman who had no other means of working than the published accounts: he had never seen a waxed-paper prepared by any other person, and yet the result was above the average of production. He merely brought this before the meeting to show the simplicity of the waxed-paper process. Whilst speaking, he wished to remark that the paper read by Mr. Griffiths was entitled to the consideration of the Society. He believed it was quite new, and Mr. Griffiths deserved the best thanks of the meeting for bringing it at once before the Society, and, through them, to the public. He believed it was chemically correct, and hoped the members would try it, and report to the next meeting their success. Since last meeting Mr. Keene had published a modification of the Fothergill process, which was

very good; and he found it as quick as the two-dram washing, without the liability to stains.

Mr. Heywood said that it was quite true that the new modification was as quick as the old Fothergill process, and the absence of stains was an improvement; but the greatest drawback, he feared, was blisters rising, which had already occurred with him: he believed it was caused by using the albumen too thick.

A vote of thanks was then passed to Mr. Griffiths, the Chairman remarking, in putting it that he had read all the published dry formulæ, and had himself tried nearly all kinds of preservative substances, but the application of Mr. Griffiths's was, he believed, quite novel.

The thanks of the meeting to the Chairman concluded the business.

New members will be received at the next meeting of the Society, which is to take place on the 9th May.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

PRACTICE.

The recommendation of colouring from the life has been given with a good purpose, as you will see if you glance from the photograph to your sitter: and just listen to me for a few minutes.

Look first at the more luminous flesh tints of nature, and then at your photograph. With nothing but transparent colours, and upon nothing less brilliant than pure white, can these be imitated: of this be sure. The next luminous tints being harmoniously associated with the first, are still brilliant; but unless the tints indicating these in your photograph be of a very faint and not too cold a tone, your representation cannot approach the truth of nature. The exquisitely delicate and pearly demi-tints seen in the retiring and other portions of the face can never be obtained upon sooty grounds, if such happen to be the character of their photographic representatives: of this also be sure; and also that cold, opaque, and intensely black patches can never be made to represent the warm and transparent appearance of shadows. You will see, therefore, the importance of obtaining a properly printed proof. But the best photograph you can obtain for colouring will always degrade the character of your flesh tints more or less, especially those applied to shadows; and to overcome this difficulty one of two methods must be adopted, viz., the use of opaque colours, which absolutely destroy the photographic shadows altogether; or of the more powerful transparent and semi-transparent pigments, which only "kill" their objectionable qualities. Hence, too, you will easily understand that a scale of tints, colours, and shades will be required for photographic colouring entirely differing from those used in ordinary painting on ivory or cardboard.*

As you are about to begin by painting flesh, it is but fair that you should first study its character. So you look very earnestly upon your model.

The fair young creature cannot sustain your thoughtful but continued gaze, and down go her silken eyelashes, while up flushes the rosy blush. There is lesson No. 1 for you, viz., the transparency of the material. Now, do you think this transparent surface, so beautifully pencilled with the tender tracery of veins, and so eloquent of the flowing blood beneath, can ever be obtained by the use of pigments mixed with white? which, as Barnard justly says, would give you the appearance of "a woman who uses a cosmetic, and dusts her face all over with it, producing a mealy whiteness, which will never bear a close scrutiny." For this reason again I use transparent colours. But the lady, your model, feeling it ridiculous to blush under the gaze of an art-student examining her simply as he would a beautiful flower, an evening sky, or any other such charming piece of nature's handiwork, is now seized with a desire to laugh, and, raising her fan, presses it upon her lips to restrain the same, although the bright eyes (saucily asserting their independence of the mouth) are full of arch merriment none the less: and here is lesson No. 2 for you, viz., the solidity of the material.

The appearance of partial transparency and that of due solidity must therefore be properly blended, if you desire to obtain the real quality of flesh in your colouring.—[See Maxims 42, 39, 47, and 46.]

Observe, in the next place, the glossy surface of the skin, as evidence of its smoothness, and be sure you preserve this characteristic. Unless the lady be a sweetheart or wife, you must take the softness of this exquisite surface on faith only, otherwise an application of the essence of tulips would, as an old joke says, prove its existence.

* An otherwise excellent little work on miniature painting, recently published, falls into the error of recommending one process for both coloured drawings and photographs.

Turning again to your model, observe that where the bones are most visible under the skin the lights are whitest, but with somewhat of a pale yellowish tinge; that the delicate carnation of the cheek is not a smooth, even tint, but is full of inequalities and beautiful variety. Above all, note the effect given by the scarcely apparent down covering the skin, modifying the tones of the demi-tints, blending and harmonising the local colours, giving a peculiar softness to the outlines, and a bluish tinge to the retreating surfaces, which is very apparent. This down being so nearly white in a fair person, has much to do with the great delicacy of the face. You will perceive that where the pinky hue of the cheek nears the jaw this tint is broken with peach-like hues, violaceous and bluish greys, and greenish and warm demi-tints, melting into and emerging from one another with the same imperceptible gradations.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

A Grateful Pupil.—Yes.

Everard.—See reply to "An Impatient One," and that to "N. S." Lessons in the use of oil colours will be given.

Ann Page.—In consequence of the many applications which have reached me I am making arrangements to receive pupils, and when prepared to do so will announce the fact in the advertising portion of this Journal; at present I have not the necessary time. Your proposition of a class is a novel one.

A Dry Colourist.—Your coloured specimen puzzled me greatly; how you could have followed my instructions and produced such results I cannot guess. Begin again and be more careful, both in reading the instructions and carrying them out practically; and if you find the tints so difficult to mix obtain them already prepared.

J. Hope, Fendstone.—The flesh is too yellow; the blues too cold and pure; you have destroyed the folds of your drapery; the hair is a daub of opaque colour, owing to the destruction of the shadows. Why use the gold shell?—refer to my remarks on the subject. Never despair, though bad; many, with better opportunities, have done much worse.

An Impatient One.—I quite understand the difficulties you and others must experience in pursuing your studies from such small instalments given at comparatively long intervals; but the matter is not within my control, and doubtless our good friend, the Editor, makes such arrangements as he can to please the various tastes and fulfil all the wants and wishes of his numerous readers, although, for my own sake, perhaps it were better otherwise. Like most men, I am not insensible to praise, but am not prepared to swallow a compliment so palpably flattering as that in the contemporary to which you refer.

N. S., Brixton.—For professional purposes I would advise you to take courage and study water or oil painting. M. Mansion is the only really artistic colourist who produces satisfactory effects on paper with dry colours; and if you still desire to practise this branch, you could have no better teacher than this gentleman would prove. I do not think the powder colours are more easily mastered than water or oil. A *little* may be done with nearly equal ease in the one or the other, but to do more than simple tinting will, in either style, be found equally difficult. The remainder of your note I will answer privately.

G. Elder.—Verily there *is* room for improvement: certainly had I not read your note I never could have imagined "a professional *artist* desirous of improving his style" had coloured the specimen now before me. *Honestly* advising you, I say you had better throw aside your past experience altogether, take up the wholesome humility of a beginner, and choose a new road which *may* lead to something better, and cannot, at any rate, lead you to a much worse result. The specimens you have seen are mine, but I do not think so highly of them as you seem to do; and, by way of excuse for admitting thus much, must add that they were painted in great haste and under very disadvantageous circumstances by another gentleman and myself, and that I have not yet had an opportunity of putting better in their place.

G., Daintree.—I am much gratified to hear of your success, and must thank you for your kindly expressions. The unnatural prejudice in favour of foreign talent certainly does still exist among *photographers* in this country, but I think it is decaying. The peculiarity has been remarkable in England throughout the whole history of her art. In our earliest chronicles we find foreign artists high in court favour, while their superiors and equals, because "*English born*," were the victims of neglect and all its attendant miseries and bitterness. The origin of the defect you describe is either in varnishing before the colours were thoroughly hard, or in painting a second time before some of the pigments used in the first were dry enough. Wash the parts to be glazed with alcohol in warm water, and the glazings will then lie properly.

Calcium.—A new mode of preparing calcium consists in submitting a mixture of sodium, zinc, and chloride of calcium to a strong heat. The sodium combines with the chlorine, forming chloride of sodium, and the zinc remains mixed with the calcium. But as the zinc is volatised while the calcium remains fixed, they are separated by raising the temperature still higher, when the zinc passes off, leaving the calcium isolated. By this method specimens of calcium weighing twelve ounces and upwards have been obtained. It is probable that analogous metals, such as strontium, barium, &c., may be obtained by similar means.

Foreign Correspondence.

Paris, April 11, 1860.

The spontaneous decomposition of gun-cotton has been the cause of frequent accidents, some of them serious. To trace the causes of this decomposition, the attention of many chemists have been at various times directed. I recently noticed a communication from Mr. Hardwich, in which he gave it as his opinion that, among

the causes which change the constitution of gun-cotton, we must include even diffused light.

M. Davanne, the eminent chemist, disputes this conclusion of Mr. Hardwich's. He states that he has kept gun-gotton both in glass jars and lying open in paper on the shelf of his laboratory, in strong diffused light, for upwards of two years, without its undergoing any change whatever, still less a decomposition: it has even been submitted to a temperature of 100° Fahrenheit, and upwards, without any apparent alteration. From my own experience, I may venture to say that whenever gun-cotton has undergone decomposition in my keeping it has arisen from imperfect washing; if the pyroxyline was in the least degree acid, decomposition has generally supervened. I obviate this risk by the addition of a small quantity of bi-borate of soda, previous to the last washings, and I make the water flow into the washing vessel at the bottom, and overflow at the top; and after the cotton is drained, I take it while wet and squeeze out the remaining water into a measure, and test it for the presence of acid. Gun-cotton so treated I have kept five years, without its undergoing any apparent changes.

I regret very much to see by the report, in your last number, of the meeting of the North London Photographic Society, that MM. Davanne and Girard's researches on Positive Printing were decried. When we consider the vast amount of labour, skill, and patient research these accomplished chemists have given to perhaps the most important feature in photography — the permanence of positive pictures — it is but courtesy to receive whatever they put forth with some degree of consideration. But in the discussion at the North London Photographic Society's meeting, the objections made to certain statements put forth by MM. Davanne and Girard were taken on a wrong basis altogether — objections were made to statements which those chemists never put forth. While they fully admit the great solvent powers of hyposulphite of soda for chloride and nitrate of silver, they say that the double salt, hyposulphite of soda and silver, formed very soon saturates the hypo with that *double* salt, and, when so saturated, the hypo is no longer a *safe* fixing agent. There can be no disputing this — the evidence abounds on every side. Our portfolios teem with evidences of sulphur "fixing," which have a very suspicious, jaundiced aspect, due to questionable toning; and, instead of contradicting *the facts* those chemists have put forth, to the manifest benefit of photographic science, *I* think we ought to receive them gratefully.

At first sight there will, no doubt, be some reluctance on the part of photographers to accept so lavish a consumption of hypo as MM. Davanne and Girard's assertion would require; but it must not be overlooked that they also state that, when the hypo bath is saturated with chloride of sodium, the *double salt*, hyposulphite of soda and silver, becomes more stable, and the bath may be used with safety. Saturation with other salts, such as nitrate of potassa, phosphate of soda, bi-borate of soda, also induce greater stability in the hypo solution.

The importance of this "fixing" question cannot be overestimated, seeing that the permanence of positive proofs is the keystone of the whole photographic edifice. Experiments conducted by the light of science can alone lead us to safe practice: empiricism already abounds *ad nauseam*. J. P.

IRON AND SYRUP FOR DEVELOPING.

To the Editor.

Sir,—I have been trying to develop wet plates with iron and a little honey syrup (made with honey in alcohol), thinking that as you suggest it for the dry process it might be the means of developing wet plates, and give sufficient intensity without using pyrogallic afterwards. I have, however, failed. Can I use the same iron developing bath twice or oftener without injuring the plates? Will bromo-iodised collodion retain its sensitiveness as long as cadmium collodion? Trusting you will excuse this string of questions.—I am, yours, &c.

R. GORDON.

[The amount of intensity obtainable by the proper use of a developer of iron and syrup is much greater than it appears to the eye. A bath should not be employed for wet plates, but a small quantity of the developer poured on to the plate, using a sufficient quantity of alcohol to make it flow readily without any pause in its course. The surplus may be poured off at once, and a small portion allowed to remain on to develop the picture. The same mixture is not fit for use a second time.

Bromo-iodised collodion can be made to keep sensitive for a very long time if judiciously prepared.—Ed.]

ALABASTRINE PHOTOGRAPHS.

To the Editor.

Sir,—I have made frequent attempts to manipulate the alabastrine process, but have generally been unsuccessful.

Although I have no difficulty in getting the pictures a good colour, as soon as I varnish them they invariably go quite black.

I have several bottles sold by Messrs. Squire & Co. for that purpose, and some made by myself from the formula given in the Journal, but each sample after the first use acts the same, and the varnish itself is quite black.

Will you be kind enough to inform me the cause of this in your next? I should be obliged if at the same time you could give me a good formula for printing glass transparencies.—I am, yours, &c. E. C.

April 4th, 1860.

[There must be some serious error in your manipulation which is not indicated in your communication; for though varnishing always detracts somewhat from the brilliancy of the pictures, there is no cause for blackening, unless indeed you omit to wash your proofs after using the re-developing solution, as it is called.

For printing glass transparencies there is perhaps no better plan than to use Fothergill plates, and print by direct contact.—Ed.]

CONJUGATE FOCI AND THE OPTICAL CENTRE.

To the Editor.

Sir,—Being desirous thoroughly to understand the valuable papers by Mr. Grubb in your few recent numbers, I had to refer to the best treatise at hand,—the "Useful Knowledge Society's" works on Optics and Optical Instruments.

Here I find the following rules:—

Rule 1. To find the conjugate focal distance: Multiply the focal distance of the lens by the distance of the object, and divide that product by the difference of those numbers.

On page 75 of your Journal, a case is assumed in which the conjugate foci are to be 8 (u) and 16 (v), and it is required to determine the focus (f) of a suitable lens. By the above rule we have $\frac{u \times f}{u - f} = v$, whence $uf = v(u - f) = vu - vf$, transposing and dividing, $f = \frac{vu}{v + u} = 5\frac{1}{3}$, as Mr. Grubb has given it.

Call $\frac{v}{u} = e$, the ratio of the foci, and which will also represent the amount of enlargement an image at the distance u would receive at v, we have $\frac{u \times f}{u - f} = eu$, whence $uf = eu^2 - euf$, or $eu^2 = (e + 1)\,uf$. Wherefore $u = \frac{e + 1}{e} \times f$; also as $v = eu$, $v = (e + 1) \times f$, which are Mr. Martin's formulæ, at page 65.

Rule 2. When two lenses are not in contact the compound focus is found thus:—Divide the product of the principal foci of the glasses by the sum minus the distance.

That is, the new focus or power $= \frac{F \times f}{F + f - d}$ Now the reciprocal of this is $\frac{1}{P} = \frac{F + f - d}{F \times f} = \frac{F}{Ff} + \frac{f - d}{Ff}$, whence in case (B), page 46, where $F = f$, we have Mr. Grubb's formula—

$$\frac{1}{P} = \frac{1}{f} + \frac{f - d}{f^2} = \frac{1}{f} + \left(\frac{1}{f} \times \frac{f - d}{f}\right)$$

Should Mr. Grubb, or any of your able correspondents, now supply a simple derivation of the above rules, and their application to case F, page 46, the whole subject would be thoroughly intelligible, I may say, to all your readers.—I am, yours, &c. C. L.

Leeds, April 6, 1860.

PHOTOGRAPHERS' HALF-HOLIDAY.

To the Editor.

Sir,—Perceiving that you are an advocate for the half-holiday, I beg your insertion of this note.

After reading in The British Journal of Photography your correspondent's letter, and your admirable remarks thereon, I decided that for two Saturday afternoons I would traverse the city and be my own witness as to whether any of the photographers had carried out your suggestion, when, what did I behold? Why, that the only establishment that was

closed (photographic I mean, as of course all the warehouses were closed) was that of a noted firm in Gracechurch Street, whose pictures few equal, and none surpass (I think that augurs favourably for the half-holiday); and I firmly believe that house suffers no pecuniary loss through its generosity to those in their employ. Your correspondent, while pleading for the half-holiday, remarks on the non-production of artistic pictures, in which he and I entirely agree, for, in my humble opinion, artistic photographs are conspicuous by their absence (if that is logical). Judging from this state of things, it leads one to think that what photography requires is either the importation of men with better talent and more artistic skill, or else that those who are at present practising it should have the opportunity of cultivating that love for artistic arrangement which is so essential for the production of artistic photographs. I prefer the latter course: let them have the opportunity to view the pictures of our great artists, and remark how beautifully the subjects are disposed. If they then make reference to their libraries, they will see that those artists did not obtain their grand ideas by remaining in-doors all the week, as it appears the photographic operator is expected to do, but that it was in foreign climes, and generally in sunny Italy, that those artists imbued their minds with the grand ideas which have enabled them to delineate, with such miraculous touches of the brush, those beautiful pictures which, had they never visited those foreign shores, would not have been there to gladden and enrapture our eyes. Now the operative photographer does not want three or four years in another clime to enable him to produce artistic photographs; all he requires is, that four or five hours on a Saturday should be awarded to him by his employers for the purpose of visiting those places of instruction and amusement which have been raised by his countrymen. I differ from you as to the day being of no consequence, as there are many places open on Saturdays which are not open on other days, or else there is an admittance fee. I would suggest that, as there is always in any place worth calling a photographer's, an operator and printer, that they might take it alternately where the means of the firm will not admit of closing, and I have no doubt that they would find that the men who enjoyed this privilege—that were in the habit of coming on Monday morning with a half-sluggish air—would then go to work with greater freshness and energy than they did when for six days, without cessation, their minds were depressed through constantly inhaling into their systems the fumes of injurious chemicals. I would ask any one who constantly works at photography, whether he does not suffer from headache and general debility, and loses that strength of mind which he possesses on a Monday morning, before the Saturday arrives, and if he does not look upon his profession as a living tomb? Of course it is a blank question for an operative photographer to think of a week's holiday. Instead of these dull thoughts haunting their minds, they would renew business with a stronger intellectual capacity and fresh ideas as to whether they could not, in their pictures, resemble this or that work of art which they had seen in their half-holiday rambles; and when a man thinks, the next thing he does is to act, and knowing this, I believe that the holiday would be productive of the most beneficial results to photography.

I hope to remain the trumpeter to a happy and pleasant season for photographers.—I am, yours, &c. J. HART.

COLLODION POSITIVES.

To the Editor.

Sir,—To bring our honourable art to perfection, it may, I think, be deemed necessary to unite three distinct accessories: chemical science, artistic taste, and expertness of manipulation. Of the first and second it is not my design at present to treat. But having had nearly six years' constant practice as a successful photographer, my experience may be of use to some of your amateur shadow-catching subscribers.

In my conversations with many photographers, and in the perusal of photographic publications, I have observed that the tendency has generally leaned to the chemical and artistic departments, and that aids have been sought from those which belonged almost entirely to the manipulatory. Bad collodion, disordered baths, and suspected developers have been, and still are, the general scapegoats of erroneous manipulation. I have frequently known the various chemicals denounced as unfit for use that were everything that could be desired; indeed, for my own part, I am so fortunate as never to meet with any bad chemicals; and though I attribute general failures to imperfect manipulation, and have often redeemed the character of condemned chemicals by using them in a proper manner, my own mode of manipulation to the chemical fraternity may perhaps be deemed execrable; nevertheless, it is successful, and that is the clenching argument.

I have observed an almost incredible amount of failures caused by the imperfect cleaning of the glass, which, in my practice, is an exceedingly simple and infallible process. It is this:—I make a saturated solution of common washing soda with boiling water, and while it is hot put in the glass, rub each plate with a rag, and let it remain there till wanted; then I wash off the soda, and rub it over with diluted nitric acid, about four parts water, wipe dry with a towel washed in soda without soap, and polish with a wash leather.

It appears to me that a great deal of nonsense is talked and written about the silver bath. My plan is this:—I make a thirty-grain solution either with distilled water or tap water, in the latter of which I previously put about two drops of nitric acid to the quart. It appears to be immaterial which is used, for I find them to answer equally well. And I may observe, for the over-exact in chemistry, that water and nitrate of silver are its only constituents; I use no iodising, or neutralising, or acidifying, or modifying process whatever, nor do I find any required. I often see it stated, too, that the bath gets weaker with use, and that it is necessary to restore it by adding silver, or replenishing with a stronger solution. But whatever theorists may say, I do not find this perceptible in practice. I am now working with a bath upwards of two years old, that is, I have not had an entire new one for that length of time, but have uniformly replenished, as waste required, with a thirty-grain solution; I have taken thousands of pictures with it, and I can assure you it is still faultless. All that I do with it is to filter when muddy, which occurs perhaps once in two or three weeks. I keep it in an open bath-trough in my dark room, without any particular protection either from light or dust.

I am often amused when I read or hear of the endless kinds and qualities and comparative merits and stages of change of collodion. Let it be only of ordinary make, without regard to any peculiar quality, or of any age, and it will do for me. I can take with it pictures either foggy or transparent, yellow or white, perfect in half-tone or imperfect, flat or prominent, dingy or brilliant, metallic or soft, merely by varying the manipulation. And as for the notion that collodion is best when fresh made, I am satisfied it is false. I seldom use any new; I keep a stock-bottle half full or upwards, into which I mix all fresh supplies, and pour off as required. It is deep in colour, almost like treacle. I put in all residues, and collodion of anybody's make, and whether positive or negative, all goes to one pot. And it will also answer for thick films to be transferred to leather, &c., as well as if made for the purpose. I have even had phials of collodion that have had the stoppers out, and been neglected for months together, till all the liquid had evaporated, leaving behind a hard solid mass, and yet it would be perfectly workable when added to the stock-bottle, and thinned with ether. And I never have any either wasted or of inferior quality.

My developer is a twelve-grain solution of protosulphate of iron, with four ounces of spirit to the gallon, and two ounces of dilute nitric acid, made by putting four ounces of the acid into a twenty-ounce bottle, and filling up with water. I put the acid solution into the water some hours *before the iron*, which appears to have a beneficial effect upon the developer. I keep it in unstopped bottles in all weathers, and develop with a glass measure, crusted thick both inside and out with sediment, &c., not washing it perhaps for three months together; and although it is said that iron developers will not keep, I have found by experience that the one I use will keep for six months, without any signs of deterioration. While I now write a photographer from a neighbouring town has dropped in, and expresses his sorrow that he cannot make an iron developer to keep.

I "fix" in an upright trough with a saturated solution of hyposulphite of soda, and filter when necessary. I never change it wholly, but replenish by adding new to the old.

You will thus see that my method is the most simple, the quickest, the least expensive, and requires the least care possible, and I may also add, that it is so certain in its results that I seldom have a failure from any cause, except in misjudging of the light. O that somebody could invent an actinometer! I can prescribe but few general rules, but I would say—

1. Keep the chemicals clean.
2. Do not mix any of the chemicals by carelessness.
3. Let the plate remain in the bath till thoroughly iodised, but no longer.
4. Learn to judge when a picture has been properly lighted.
5. Ascertain the maximum and minimum power of the developer, and *develop by time*, for I find that time is of as much importance in developing as in the camera.
6. Keep the temperature above 50°.
7. Let the whole process be gone through as quickly as possible, and it must be remembered that what delivery is in oratory, so is manipulation in photography.

No doubt some of your scientific readers will demur to this unscientific letter, but I would remind them that a process must be judged by its results, and that the public have pronounced their judgment in favour of the method here submitted.

I don't know whether I am more fortunate than other photographers in procuring pure chemicals, but I have always been supplied by the firm of Harvey, Reynolds, and Fowler, of Leeds, one article excepted. For the last eighteen months or so, I have mostly used Hanson's collodion, on account of the lowness of the price, being the cheapest I have met with, and answers the purpose quite as well as the dearest.

Having written a longer letter than I intended, I will now conclude with the remark, that it is my impression that more careful attention to manipulation will generally prevent the failures attributed to bad chemicals.—I am, yours, &c.

March 7, 1860. ISRAEL HOLDSWORTH.

[We like exceedingly to look at all sides of a question, and are at all times happy to afford correspondents an opportunity of expressing their opinions upon matters photographic, hence the insertion of the preceding letter. We may, however, be permitted to repudiate anything like concurrence in the views therein expressed. Any further comment we shall leave to our correspondents.—Ed.]

THE CENTRAL SPOT.—THOROUGH WASHING.

To the Editor.

Sir,—Allow me to offer you another explanation of the cause of the "foggy-looking spot" in the centre of negatives, which you speak of in your last leader. I was at one time very much annoyed by this defect when taking views with the front lens of a portrait combination, and was for some time unable to find out the cause. At last I discovered that it was produced by the reflection of light from the interior surface of the lens tube, which though blackened, as usual, was still capable, from its smoothness, of reflecting a considerable amount of light. I therefore lined the tube with black paper, quite free from glaze, which completely obviated the difficulty, so that I was never troubled with the spot again.

With all due deference to your judgment, I cannot help thinking your explanation very unsatisfactory. I cannot at all see how the external shade can be the cause, and the admission of the oblique rays by its removal could only aggravate the defect, if indeed it did not also produce fogging over the whole picture.

I am obliged to Mr. Hardwich for his remarks on my last communication. The object of washing the plates in a *measured* quantity of water was to obtain uniformity in sensitiveness, by leaving a definite proportion of free nitrate of silver in the film. The degree of sensitiveness seems to depend to a great extent upon the quantity of free nitrate remaining. Pure iodide of silver is totally insensible to the influence of light; for iodised calotype paper may be exposed to the direct rays of the sun for hours without injury, and a collodion plate would be equally insensitive if the nitrate were *entirely* removed. I believe, however, that it is impossible to remove the free nitrate *completely* from a collodion film by any ordinary amount of washing, and that the most thoroughly washed plate still owes its sensibility to the small quantity of nitrate still remaining, and perhaps also to a portion of chloride which will be formed if common water be used for the washing. It seems now to be considered that free nitrate may be replaced by chloride or other insoluble salt of silver, without impairing the sensitiveness of the plate. I must own I was somewhat incredulous as to the truth of this statement when it first appeared, and have not yet had an opportunity of satisfying myself by experiment, but it seems now to be generally admitted as a fact. If this substitution should prove practicable, it will probably increase the keeping capabilities of the prepared plates. As soon as I am able to resume my photographic pursuits I shall give Mr. Hardwich's suggestions a fair trial.—I am, yours, &c.

April 5th, 1860. R. W. FORSTER.

[It is clear that our correspondent has quite misunderstood our remarks. If he will refer to the article he will perceive that our allusion was to a *double* combination with a *central* stop; moreover, we also used the following words:—"The only precaution to observe would be, to be quite certain that the interior of the tube is properly coated with *a dead black substance of an appropriate kind.*" The external shade, if too long, or of too small a diameter, cuts off a part of the effective aperture for oblique rays, and thus causes the edges of the picture to be less intense than the centre: he has only to try the experiment to be convinced of this fact. If the interior of the tube be non-reflective no inconvenience from the absence of a shade will be found.

We are by no means satisfied of the correctness of the oft-repeated assertion, that "pure iodide of silver is totally insensible to the influence of light." The case cited proves nothing of the kind, but simply that calotype paper exposed to sunlight can, *by subsequent treatment*, be rendered effective for receiving an impression. We have good reason to believe that pure iodide of silver *is* sensitive to light. We are certain that the presence of free nitrate of silver is not an essential condition to the existence of this quality, and we do not admit that there is any question as to the practicability of substituting for the nitrate a chloride or other insoluble salt of silver. This is a *fact* which we have personally verified repeatedly, and, what is more, the practice is pretty commonly followed at the present time.—Ed.]

INTENSIFYING A NEGATIVE.

To the Editor.

Sir,—Will you favour me by replying, through the medium of your valuable Journal, to the following questions?

I am now developing my negatives with iron, but I cannot intensify them enough to get good positive prints from them. The iron developer I use is composed of fifteen grains protosulphate of iron, fifteen minims glacial acetic acid, and four ounces of water. I then clean them off with cyanide of potassium, &c., and try to intensify with the following: six grains of pyrogallic acid, thirty minims of glacial acetic acid, thirty minims of alcohol, and eight ounces of water: I make this quantity for convenience. The result—*fog.*

Should the negative be cleaned off with cyanide before intensifying, or merely washed well with water, then intensified, and, last of all, cyanided in the usual way?—I am, yours, &c. LYON.

[Your iron developer is too weak to "flash out" your picture in a few seconds of time, and by keeping it on too long, of course, the result is—*fog.* Use *one* ounce of *distilled* water instead of the four at present employed; keep it (the iron developer) on the plate as short a time as possible, then proceed as before, but omit the alcohol with the pyrogallic developer, with which, however, you must of course use a few drops of nitrate of silver solution. You may intensify either after or before clearing, but we prefer after. A thin fluid collodion is not so well adapted for use this way as one thas has more body.—Ed.]

A REAL BLESSING TO MOTHERS!—PURPLE VELVET AND PURE CALOMEL.

To the Editor.

Sir,—Hoping you are well as this leaves us at present I takes up my pen in hopes you will exquse the libarty I takes in addressin of you unbenone to you as I am. But a fond mother's feelinks must have went. I am a pore widow letting lodgings and a large family seven living and two berried thanks be at a small watering place. My eldest boy plows the briny wave as he sings when he comes home and my youngest is a golding aired angle of six come fust of May. It is of these two that the mother's 'art must speak. When last my boy was at home he went to a "portraitist" "a poor professional" "who has talent and patience" the two pair back's brother who helps him on Sundays and had his likeness took in a splendid frame with the mole on his cheek and his turnup nose with a little ring to hang it up by quite natral for a shilling. "Mother" says he "this aint a common sixpenny touch but a Albastrine Photograph" readin from a label on the back quite proud like. "Well my boy" says I "it is a good likeness and I vally it whatever they calls it." Thinks I to myself "Alabastrine indeed" "that's a bit of Bunkum" as my diseased husband used to say. To make a long story short last Sunday my youngest who is sometimes a ailin' as youngests of nine often does as other mothers as well as me can testerfy, well Sir as I was sayin she had been up in the two pair back's bedroom a lookin at the ships when down she comes with a paper in her hand. "Polly" says I "you norty child how dare you touch the lodgers things." "Taint no use mother" says she "I found it in the grate." Well thinks I it cant be of much use then. With that I takes it out of her hand and begins to read it thinking it might be "Reynoldses" or somethink that way. So I reads "Photographic Quæries" By Thomas Epsom BA of Alderney. Oh thinks I you are all about acids and vitrol and stuff for the two pair back's shirts is stained awful with the vitrol he uses and I was just agoin to shove it under the kittle to make it bile when the words "Alabastrine Process" kitches my I. Ah thinks I more Bunkum and I read and on all about "portraitists" and "shimmer" and "purple velvet" and "calomel." Only to think that the shadders of my boy's coat was purple velvet and that the mole on his cheek and his turnup nose was "pure calomel." I quite larfed I did indeed. Three hours later when all the shops was shet and I had nobody to send if they wasnt for the others had gone to Sunday School and I was alone with my golding aired dear. I had kep her at home as she fell porely and sickish like. Well Sir she got wus and wus till she was that bad that I thought she would prespire in my arms. Oh thinks I if I only had some calomel—calomel's the only thing for you and there's nobody to send and the shops is shet if there was. I kast my ise around in disparc when kitching site of my boy's likeness it flashed across me and I come all over like. "The lights is pure calomel!" It was done in the twinkling of a bed-post though I felt like Isaac sakrifijing his son Abel—my golding aired darling had swallered her brother's 'ed fase shirt front one of his 'ands and the pillar and curting. The effex was magik. In half an hour it had acted—you are a father Sir no doubt and I need not explain—it acted and by the time the others had come she was a sleepin the sleep of the innercent in her little bed and the frame was 'anging again on its nail with only my boy's neeze, one 'and, and the legs of the cheer showin'. But what odds the rest of the picture is purple velvet. "Can anything be more beautiful?" "If it can, take away the velvet and put it there instead." This last and a good deal more is agstracted from the "Quæries," so if there is any bad spellin or anythink you can't understand it is Mr. Epsomses fault not mine.

Aksin your parding for being so gossipin like.—I am, yours, &c.

PENELOPE ANN SPRIGGINS.

ANSWERS TO CORRESPONDENTS.

Mercator.—A little more citric acid is all that you require.

A. N. Scott.—The stereographs have at length come to hand.

A. Y. V.—H. B. C.—R. T. Dick—An Amateur: answers to these in our next.

J. L. Fysh.—The index and title page to our last volume was issued, as promised, with the number published on the 15th January last. We cannot understand how it is possible for you not to have received it.

F. Fordham.—We know of nothing so convenient for your purpose as the washing tray, or rather *slop* tray, introduced by Messrs Murray and Heath for use in Smartt's tent. It consists of a waterproof material, kept in form by a light wooden frame, which takes to pieces and allows of the tray being rolled up; a flexible tube from one corner carries away the washings, &c., into any vessel placed to receive it. You may, with one of these trays, readily develop negatives on glass in the hotel bedroom without running any risk of having to pay for spoilt table covers, &c.—that is, unless you are very clumsy.

Received.—C. B., H. E. Roscoe, with thanks.

☞ Notwithstanding the increased size of the present number, several communications already in type are unavoidably postponed.

All Advertisements *and* Letters *on the* Business *of this* Journal *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 117, Vol. VII.—MAY 1, 1860.

It is not a little amusing, as well as instructive, to take an occasional retrospective glance at the state of our art, in its various ramifications, as it existed some few years back. It is not only that we become aware of the enormous rapidity of its development by so doing, but we cannot fail to be struck with the vast amount of change, both in opinion and practice, that has occurred in a comparatively short space of time. What, for instance, can be more different in its present and past conditions than the process of printing positives upon paper? How simple in its early days! — how complex in its present manipulations! Then, we were content, it is true, with a sketchy affair, of a vile brick-red hue, as if "knocked off" in a hasty way with a piece of red chalk; now we are particular, and must have our rich purple or black tones, with every gradation of half-tone preserved in the utmost perfection. The trouble of producing the former was next to nothing — which is about the value of such a print—while the latter is not to be acquired without a considerable amount of labour; but then it is really worth something. As the mansion is a development of the original mud hovel, so is the positive printing of to-day the natural sequence of that of yesterday. The present condition of things has not been arrived at, however, by mere empiricism, but depends upon the results of careful and well-directed investigations; often entered upon, it may be, from some chance observation, but entered upon designedly, and in order to clear up what has appeared anomalous or obscure.

We have been led to these remarks after perusing a paper upon this subject, read at a recent meeting of the Manchester Photographic Society, by Mr. W. T. Mabley (a portion of which appeared in our last issue, the remainder being given in the present number); and, as it is one of interest to every photographer, we propose drawing attention to a few of the points specially treated of in the communication to which we have alluded.

We think it but an act of justice to remark, *en passant*, that there is perhaps no photographic society — certainly no provincial one — that exhibits a greater amount of active vitality than that at Manchester; and the chairman who presided on the occasion when the paper by Mr. Mabley was read, was altogether too modest in his estimate when he remarked upon its position as being *likely* to be second to none — a position he might at the time have justly claimed for it.

In perusing Mr. Mabley's paper, the first thing that strikes us is the probability that this gentleman is unacquainted with the researches of MM. Davanne and Girard upon the subject of positive printing, as he states that it has appeared to him "that several matters which might or might not be of importance have never been practically and systematically examined," and then cites the condition of the nitrate bath as an instance. Now, a very systematic investigation has been executed by the gentlemen named; but we are of opinion that similar researches by a competent and independent experimentalist are imperatively called for, as there are several conclusions at which our French brethren have arrived which appear to us not necessarily to follow from data furnished by their own experiments. It is not altogether improbable that investigations under somewhat altered conditions may lead to different results as a foundation for theorising.

We are convinced, from the earnest manner in which Mr. Mabley has entered into what is evidently a labour of love, that he will not regard our comments in any other light than as an attempt to elucidate one or two points, by drawing his attention to some obscurities in his communication — obscurities that probably did not exist to those who were present at the reading of the paper. He states that the negatives employed in his experiments were made by causing "light to pass through strips of paper of different degrees of transparency." Query—Did he use paper negatives? or were the slips of paper used wherewith to produce a glass negative?

We next notice that the attention of the author was directed towards the *sensitiveness* of prepared papers; but, on reading further, we are by no means assured that he means thereby what is generally understood by sensitiveness—that is, aptitude to receive an impression *rapidly*, and not the capability of darkening by a sufficient exposure to any required degree of intensity, which is what we gather from the paper as being Mr. Mabley's meaning of the term. It is, of course, but of trifling importance which definition he employs, but highly necessary that we should understand in which sense it is used; and we trust that Mr. Mabley will in his next communication indicate the same. If we have wrongly interpreted the meaning attached by him to the term, then his experience somewhat differs from that of the French operators, who found that either an acid or an alkali added to the neutral nitrate of silver bath retarded the darkening action of light upon chloride paper, in which albumen was absent; but these may possibly not be opposed conclusions, the presence or absence of the organic body varying the primary conditions of the experiment.

It is suggested that albumenised paper should be stamped by the makers, so as to indicate the quantity and kind of chloride used in its preparation — a very useful hint to follow out: there is, however, already one firm which supplies the information, though not in the manner above named.

Mr. Mabley tried the difference of effect produced by printing through a piece of thick plate-glass, and also by omitting the same, and estimates the retardation of the former at about twenty to thirty per cent. in time — a much greater difference than we were prepared to expect, though we do not attach so much importance to it as the author of the paper himself does.

There is one experiment in particular which has a very useful practical bearing: it shows that papers prepared upon a faintly acid (nitric) bath tone more rapidly than those from neutral or alkaline ones, and that we thus have a probable means of overcoming the difficulty of toning which some papers possess. But this is not all. It is well known that albumenised paper, sensitised upon an acid bath, will "keep" in ordinary circumstances much longer without becoming discoloured than if prepared upon a neutral bath, so that two important advantages are attained by the same proceeding.

A piece of sensitised paper, kept for six months in one of M. Marion's preservative cases, was not found, although highly sensitive and but little discoloured, to tone properly; but we do not think any satisfactory conclusion can be drawn from this experiment, because neither the amount of chloride employed nor the condition of the sensitising bath were known to the operator.

Our object in making the preceding observations has been, not for the purpose of opposing the conclusions arrived at, but solely with a view to directing attention more pointedly to them, and to eliciting, if possible, from the author of the paper a few explanatory words relative to some passages which we consider are at present open to misconception.

We shall look forward with considerable interest to the continuation of the subject as promised.

A CALUMNY REFUTED.

[As a rule we are averse to admitting anything like personal controversy into our columns: it is, however, generally admitted that there are exceptions to every rule, and certainly this is one of them. Mr. Grubb has been assailed in consequence of his contributions to this Journal; we therefore consider that he has a right to claim the insertion of the following correspondence.—Ed.]

To the Editor.

Sir,—It is matter of no surprise that the projector of the new panoramic lens should feel excessively galled at the result of the late discussion in London (as published in all the Photographic Journals but his own) on that production, which, in his eyes, was destined to eclipse all other lenses in photography. But, I am by no means content, nor shall I quietly submit, to be constituted the "scape-goat" on which the disappointed projector shall unscrupulously wreak his resentment or vent his spleen. I have contributed but a very small share towards the general condemnation of the lens. I only showed what kind of projection it would give, leaving it to others to approve or disapprove of the same; and no one has need to be more dissatisfied with that projection than the aforesaid projector, inasmuch as he has for a long time past been crying out against using a lens having (or giving) any distortion at all, while *his panoramic lens produces a picture which, when flattened out, trebles the distortion created by any previous lens extant.* It will be within the recollection of, perhaps, not a few of your readers, that, some years since, I was placed in the unpleasant position of having to defend myself from a very impertinent and groundless attack of the projector of the panoramic lens, and who, subsequently to the time alluded to, became editor of a photographic serial. The pages of the *Journal of the Photographic Society* are evidence as to whether I conducted my defence in a becoming manner. There are, however, persons who, once discomfited, will carry their resentment down to the grave. A considerable time (I think about two years) passed, during which I purposely and studiously avoided everything which could in any way interrupt a return to good feeling, but which time, I regret to say, was employed in an opposite way by the said editor. I avoided looking into his publication until repeatedly urged to do so. At length, seeing that it contained matter against me of a libellous character, I wrote a note to the editor, and received a characteristic reply. In addition to which I have lately received another letter of the same stamp from the same party, which he has published nearly *verbatim* in his journal of the 15th January. This last production I am not alone in considering at once impertinent and threatening. Its impertinence is beneath my notice, and *its threat I meet* by requesting you to publish those letters which the said editor insinuates that I would desire not to have published. If I had any such desire, it was on his account, not on my own. The correspondence is as follows:—

[Copy.]

No. 1.—Mr. Grubb to Mr. Sutton.

No. 15, *Leinster Square, Rathmines, Dublin, Oct.* 27, 1859.

Sir,—A friend of mine having lately sent me a number of your publication, dated August 15, 1859, I find at page 204 of same the following words:—"Every one knows, except Mr. Grubb, of Dublin," &c. Now, sir, I feel fully justified in calling upon you as the editor of said *Photographic Notes*, to inform me, firstly, whether I am, or am not, *the* Mr. Grubb alluded to in the above-quoted passage? And, if I be, then, secondly, on what grounds you have, after a perfectly unnecessary mention of my name, held me up to public view in your publication, in a manner libellous in itself, and which, if true, would make me unfitted for the responsible situation I hold as Engineer to the Bank of Ireland.

I enclose a stamp, and shall make such use of your reply or silence (as the case may be) as I think fitting.

I am, Sir,

(Signed) Thomas Grubb.

To Mr. Thomas Sutton, St. Brelade, Jersey.

No. 2.—Mr. Sutton to Mr. Grubb.

St. Brelade, Jersey, Oct. 29, 1859.

Mr. Thomas Grubb,

Sir,—I hasten to reply to your note of Oct. 27th.

1st, *You* are the Mr. Grubb to whom I alluded in my *Notes* of August 15th.

2nd, The grounds on which I have "held you up," &c., are these:—I said, in *Notes* of August 15th, "Everybody knows (except Mr. Grubb, of Dublin) that a large single view lens, with a stop in front, gives more distortion of the marginal objects of the picture than any other optical arrangement which could be devised." And I now repeat that everybody, except yourself, knows this; for you say in your advertisement that "the aplanatic lens gives far less distortion of the image than the ordinary view lens;" while everybody knows that your aplanatic lens is in its external form, size, and position of the stop, identical with an ordinary single achromatic view lens, and that the distortion which it gives is precisely the same. Everybody, I say, must know this, except yourself apparently.

If you require *proof* that your aplanatic lens gives considerable distortion of the image, here it is:—

First, Your lens was tried by a committee of the Photographic Society of Scotland, and in their report they state that the vertical lines on the margin of the picture are bent inwards at their extremities.

Secondly, I inclose you a print which I received a day or two ago, from a negative taken by a distinguished professional photographer, whose name and address are written upon the back, and in reply to my query, addressed to him, as to what lens he used to produce so much curvature of the column at the left hand side of the picture, he said, "These views of ——, where the pillars are crooked, were taken with a pair of Grubb's aplanatic lenses, and I was very much disappointed with their working." I quote from his letter, which is now before me.

The above statements take the question out of the region of interminable talk into that of fact.

But I don't see how all this affects your position as Engineer to the Bank of Ireland. If you patent a lens, and advertise it, and sell it, and a professional photographer buys it, and takes pictures with it, and sells them, and expresses an unfavourable opinion of the lens, he has a right to do so; and if the editor of a journal, or a lens committee, describes your patented lens, and discusses its theory, and pronounces it faulty,—all that is perfectly fair and lawful; but I do not see how it affects your position as Engineer to the Bank of Ireland. I advise you to take a less serious view of the matter. Surely the directors of that bank could not think less highly of your engineering abilities from your having made a slip in optics. Take comfort, then. Your tenure of the responsible and no doubt arduous office which you hold as Engineer to the Bank, cannot surely depend on your knowledge of optics.

Pray make any use you please of this letter, as I shall do of yours. And if you think my statements contain anything libellous I inclose you the address of my solicitor.—I am, Sir, your obedient servant,

THOMAS SUTTON.

P.S.—Since the professional photographer whose print I inclose takes quite as high a standing in photography as Mr. Bedford, you will no doubt think it only fair to the public to add his remarks on the working of your lens to the other statements contained in your advertisement.

Be good enough to observe that you have provoked this reply from me by your absurd letter.

The address of my solicitor is—Mr. Evans, English Solicitor, King Street, St. Helier's, Jersey.

In conclusion, I have merely to add that, having shown the above correspondence to several persons, they have agreed with me in considering my note as a straightforward letter of business, with which there is, under the circumstances, no fault to be found, and the letter I received in reply, to be an addition of impertinence, if not of insult, to injury; while that which the said editor, in his lately-published production, is pleased to call his "good-natured forbearance"(!)—(subsisting, it should be observed, under a threat)—is esteemed by myself and others as a crowning cap of *unwarrantable effrontery.*—I am, &c.

THOMAS GRUBB.

Dublin, April 24, 1860.

ON THE REACTION OF CHLORIDE OF SILVER UPON THE HYPOSULPHITE OF SODA.

By George Dawson.

[Read at the Meeting of the North London Photographic Society, April 25, 1860.]

At our last meeting I hastily (and, I fear, rather imperfectly) reported the result of an experiment I had undertaken for the purpose of disproving a statement respecting the solvent powers of hypo upon Ag. Cl. I had not, at the time of my making that communication to you, been able to obtain a report of the *modus operandi* by which MM. Davanne and Girard had arrived at their rather startling conclusions. It was in the hope—vain as it turned out to be — of my obtaining this report that I deferred the experiment, already before you, to the last moment. Such as it was, it dealt directly with the question at issue, and, as you are now aware, was strikingly in accordance with the views of one of the most eminent chemists of the present day,— Mr. Hardwich.

Having now carefully perused the, in some respects, valuable paper of MM. Davanne and Girard, and tested their experiments, I venture to submit that their conclusions are not warranted by the facts of the case. They assert that "if we take a quart of a solution of hypo, of the strength of ten per cent., and stir into it forty grains of freshly-precipitated chloride of silver, the latter will be dissolved, and form the normally saturated solution spoken of above."

Further, as to the practical bearing of this, they remark:—"Now, we know that a whole sheet of paper contains, after sensitising, about twenty-seven grains Ag. Cl. only; therefore, when a sheet and a-half, previously freed from nitrate by washing in water, is passed into a bath containing a quart of hypo solution of the strength of 10 per 100, the bath will be saturated with this double salt."

In support of this assertion they adduce the following experiment, and this only. I go on to quote:—"In placing a solution of hyposulphite of soda of 10 per 100 in contact with a great excess of recently-precipitated chloride of silver, filtering the liquor and abandoning it to repose, we recognise at the expiration of a very short time that a strong proportion of double salt is deposited in the crystalline state, very pure and white. If we then seek to determine the richness of this liquor, which does not alter when exposed to the air, and which must be considered as corresponding to the saturation of the hyposulphite by the double salt, we recognise with astonishment that this solution does not contain at 60° F. more than 27 grains of silver in every litre (35 ounces), which corresponds to 36 grains of chloride of silver to 25 drachms of new hyposulphite."

They have selected a rather weak solution of hypo, viz., ten per cent. This, however, is not of much importance in the present inquiry, inasmuch as I could scarcely find any appreciable difference in the relative quantity of Ag. Cl. taken up by a ten per cent. and a forty per cent. solution to reach the point of supersaturation,— the only difference being greater rapidity of action on the part of the stronger solution; but in both an increase of temperature in the operating-room increased in a corresponding degree the rapidity of their action.

I may as well note here some facts which will save me the trouble of considerable repetition hereafter. During the progress of the following experiments the temperature of the room varied from 40° to 65° F. In every solution test paper was placed, and when any acid reaction showed itself the fact will be mentioned. The Ag. Cl. was freshly precipitated by Na. Cl., washed, dried, and added to the hypo in small quantities. Both the hypo and the Ag. No_5 were of good but not pure quality — the solvent for the former being ordinary spring water.

Having made, then, several solutions of ten per cent. hypo, I dissolved in one set of these Ag. Cl. in the proportion of one by weight to three hypo crystals. This class, for want of a better name, I shall call Test Solution No. 1.

In another set I dissolved rather more than ½ Ag. Cl. Test Solution No. 2.

In a third set Ag. Cl. was added till the white crystalline precipitate fell abundantly.

This was probably Herschell's second salt, consisting of one equivalent of hyposulphite of silver with one of hyposulphite of soda. $Ag\,O, S_2\,O_2 + Na\,O, S_2\,O_2$. Test Solution No. 3.

The behaviour of these sets of solutions, under the tests to which I subjected them, was as follows:—

Test Solution No. 1 (*a*) by evaporation yielded a crop of brilliant, clean, cut crystals, very soluble in water, in fresh hypo, and also in a portion of its own liquor removed before evaporation.

(*b*) In another portion of No. 1, no precipitate of any kind showed itself at the expiration of three weeks, although exposed to the air. I then fixed with it a positive stereograph on paper, which certainly bears all the characteristics of perfect fixation, and stands a severe test for the presence of sulphur and sulphides, by not giving off the unmistakeable smell of sulphurous acid when heated.

Test Solution No. 2 on evaporation yielded the same sort of crystals as No. 1; a little more defined and brilliant (perhaps an accidental circumstance), also soluble in water, and in other respects comporting itself in a manner precisely similar to No. 1.

Test Solution No. 3, (*a*) the precipitate insoluble in water, but perfectly soluble in its white state in fresh hypo; this new solution again on evaporation yielding crystals similar to Nos. 1 and 2, soluble in water. (*b*) The precipitate on a sand bath at about 180° Fah., quickly resolved itself into sulphide of silver, going through the regular gradations from white to yellow (at which stage it ceases to be soluble in hypo), brown, and black. (*c*) The instability of No. 3 manifested itself when exposed along with its supernatant liquor for a few days to the air. Symptoms of acidity at the end of that time showed themselves, the $Ag\,O, S_2\,O_2$ being gradually decomposed into $Ag\,S + S\,O_3$; but this solution was standing in a warm position. On the other hand, another similar solution has remained without any symptoms of decomposition, in a pretty even temperature under 60° more than a fortnight.

I shall not trouble you with listening to further details. Those already stated are only a small portion of what I have collected, all tending to the same end. Enough has been mentioned to show that Ag. Cl. in hyposulphite of soda exhibits no tendency to crystalise nor to decompose, until one part by weight of the former has been added to two of the latter salt: a broad enough margin will be left for impure materials if we say one to three. You will observe I have carefully kept out of view the influence of Ag. Cl. decomposed by light, of the organic and argento-organic compounds, all which in practice may, and probably do, modify the results. Other causes, we know, greatly affect the stability of a hypo bath in *any* stage of its progress towards saturation, such as the presence of acids, nitrate of silver, and so forth. Any one who tolerates the presence of this latter class where they have no business to be, will be amply repaid in faded proofs and much vexation. It is not my intention nor object at the present time to enter into the conditions of a stable bath, and discuss its disturbing causes. These have nothing to do with the question at issue between MM. Davanne and Girard and ourselves. They make a clear and distinct statement, and found it entirely on what I consider a fallacious experiment. They throw in a large excess of Ag. Cl. into a ten per cent. solution of hypo and filter the liquid, in which they find only a very few grains of silver. I have not yet finished my repetition of this experiment; but I have gone far enough in their direction and in my own to induce me to believe that I have found out the source of their fallacy. The facts I have as yet ascertained are these:—

I saturated a ten per cent. solution of hypo with Ag. Cl., and continued adding the latter till hyposulphite of silver ceased to fall. Part of the liquor was boiled in a test tube, without the expected deposit of Ag. S. It then occurred to me that, if this body were absent, it might contain chloride of sodium only; and this surmise seems to be borne out by the few tests I have as yet had time to apply. They are as under:—

Nitrate of silver produced a copious precipitate of Ag. Cl., with all its characteristic properties.

Sulphuric acid — a slight milkiness.

Nitric acid — the same.

Hydrochloric acid — no effect.

On evaporation, a crystalline residue appeared in considerable quantity, of a saline taste, and quite soluble in water. A piece of paper dipped in it, dried, and floated on nitrate of silver, was very sensitive to light. [Print exhibited.]

Should these strong indications lead to the proof that my surmises are correct, it would not, I think, be great heresy to doubt the existence of Sir John Herschell's second salt as the highest combination of hyposulphite of soda with chloride of silver. The formula then would be, not $Ag.\,Cl. + Na\,O, S_2\,O_2 = Ag\,O, S_2\,O_2 + Na\,O, S_2\,O_2$, but $Ag.\,Cl. + Na\,O, S_2\,O_2 = Ag\,O, S_2\,O_2 +$ Na. Cl. left in solution. The existence of the first salt, also, viz., $Ag\,O, S_2\,O_2 + 2\,(Na\,O, S_2\,O_2)$, as a distinct body, would thus also be highly problematical, inasmuch as it would only represent a certain stage on the road towards the formation of the higher salt. Certainly it has no existence in the sense in which MM. Davanne and Girard describe it, viz., as a salt prone to crystallise and decompose in the presence of hypo and water.

According, then, to this supposition, had MM. Davanne and Girard thrown in a little more Ag. Cl. into their ten per cent. solution of hypo, the probability is, the result of their analysis would have shown a still smaller per centage of silver remaining in the liquor—in truth, only the small quantity dissolved by the Na. Cl. in solution.

I have thrown out these remarks merely as suggestions, naturally arising from the unexpected phenomena of my concluding experiment. It is to be hoped some able chemist will take up the subject, and thoroughly investigate and settle this important and difficult question.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 3.

On re-perusing my last letter, in which an attempt was made to reconcile certain discrepancies in the reports of Messrs. Hughes and Morgan, members of the Collodion Committee, I find that I did not convey my meaning quite clearly. The fact of a difference in the strength of the developer, or in the amount of retarding acid, might indeed explain the conflicting statements regarding the sensitiveness of a given collodion; and I am still of opinion that a collodion must be used both with a powerful and also with a feeble developer before its capabilities of giving a rapid impression can be determined. If, for instance, a collodion, containing iodide simply, were compared with one containing both iodide and bromide, the former might yield a picture in one half of the time when the developer consisted of three quarters of a grain of pyrogallic acid to the ounce of water; but if the proportion of pyrogallic acid were increased to three grains to the ounce of water, then the bromised collodion would be nearly equal to the other as regards rapidity of action—the fact being that the presence of bromide increases the difficulty of bringing out the latent image.

The part of my last letter with which I am not quite pleased, on again looking it over, is that referring to the effect produced when a collodion film becomes surface dry, previous to its exposure in the camera. In all probability this has much to do with the want of agreement between the results obtained by landscape photographers. I will give an instance. Some time since two bottles of bromo-iodised collodion were sent to me, labelled No. 1 and No. 2, with an inquiry, why the intensity of the image was so much greater in No. 2 than in No. 1? On examining them it appeared to me that, so far from the intensity being greater in No. 2, No 1 had decidedly the advantage in that respect; and from what I was able to gather as to the mode in which the pyroxyline had been manufactured in each case, undoubtedly No. 1 seemed on theoretical grounds to be the better calculated for conferring intensity. The only difference in the conditions under which the two sets of experiments were made appeared to be, that whilst my own were conducted at a moderate temperature, in a large and airy developing room, the experiments of my friend had been carried on in a room of a small size, at the top of the house, and heated by the sun. Now, the film from one of these two collodions was of the parchment kind, tough and horny, whilst the other was of a more open and pappy description, although far from being what is termed powdery. At common temperatures the parchment film gave the most density, but at very high temperatures this film suffered more than the other from shrinking; it became in a measure impervious to liquids, and did not allow the developer to penetrate. The formula with excess of alcohol, which Mr. Sutton advocates, ought to relieve us partly from this difficulty of drying up; and when the hot weather returns it is my intention to try it with the parchmentised pyroxyline, and with a mixture of iodide and bromide in the iodiser. The strength of alcohol which I should prefer would be the spirit of ·805, and the proportions about five of alcohol to three of ether. With simply iodised collodion this formula, although not so sensitive as the ordinary one, appears to answer in other respects, but hitherto I have not fully tested it with bromide and iodide combined.

Mr. Fenton states that in using bromo-iodised collodion on large plates, and with lenses of long focus, he is able to obtain enough intensity in the winter, but experiences a greater difficulty in the summer. Is this difficulty occasioned by a drying up of the film, or has the employment of sulphate of iron as a developer to do with it? The general opinion with regard to sulphate of iron as a developer for simply iodised collodion, is that the plates lose intensity more by over-exposure, and that the image is flatter under such circumstances than when pyrogallic acid is used. It does not, however, follow that this observation should apply to a bromised collodion, since, with such a collodion, there is far less difference between the action of pyrogallic acid and that of sulphate of iron, as regards the blackness of the negatives which they respectively produce. Careful experiment can alone decide the point. At present the fact remains unexplained that it is difficult to use parchmentised collodion, when bromo-iodised, if the plates are large and the weather very hot, the collodion being developed with sulphate of iron, and the film rather over-exposed than otherwise: the defect complained of is not exactly solarisation of the sky, but a want of vigour at every part of the image.

ON PHOTOGRAPHIC PRINTING UPON PAPER.

By W. T. Mabley.

[Read at the Meeting of the Manchester Photographic Society, April 4, 1860.]

(Concluded from page 111.)

I now pass on to the subject of toning by alkaline solutions of gold, and to illustrate it in the same manner as I have done the sensitiveness:—the standard paper and nitrate bath being as before, the former salted with ten grains of chloride of ammonium to the ounce of albumen, and floated for six minutes upon a sixty-grain nitrate. In toning these prints, the two constituting a pair were treated simultaneously, so that each was submitted as nearly as possible to the same chemical action. The trials being for comparison, any toning preparation might be used. I may state, however, that I adopted chloride of gold, to which carbonate of soda was added. Here is the first experiment, one print being on paper sensitised with the sixty-grain bath, and the other with a ninety-grain bath. It is remarkable that the weaker bath gives the darker print. This may be accidental, by reason of some peculiarities in the pieces of paper, and must not, I think, be taken as positive evidence to establish a fact; but the prints are so near in tone that we may, I think, fairly assume that no great advantage is derived by using a ninety-grain bath instead of a sixty-grain, without increasing the amount of chloride. It may indeed happen that an excess of free nitrate beyond a certain point has an injurious effect when prints are toned with alkaline chloride of gold; but this is quite at variance with received notions of photographic printing; and I express no confident opinion, reserving it amongst those things to be more fully investigated.

The next example is a comparison of prints floated upon the sixty-grain standard bath, and the old bath I referred to when speaking of sensitiveness. Here we find no difference; in each case the tone is the same, and I think, therefore, that we may safely conclude that the impurities which accumulate in a printing bath neither impair the sensitiveness or the toning quality.

Here are prints prepared upon the sixty-grain standard bath. Compared with others sensitised upon a bath having a faint alkaline reaction, there is not much difference in tone, but the sixty-grain bath, which I have before stated was slightly acid, certainly has the advantage. I wish this to be particularly remarked, on account of the next experiment.

Here we have prints prepared on the standard sixty-grain bath, and on another of equal strength, to which two drops of nitric acid has been added to each ounce of solution. The contrast is most remarkable in both pairs of prints; but the one pair, not having been pushed so much as the other, does not show it so distinctly. There is, however, the same contrast: the prints from the nitric acid bath being in one case quite purple, as opposed to brown, and in the other a blue black, as opposed to purple. These nitric acid prints, therefore, have clearly toned much faster than the others, and it would therefore appear that we have a ready means of overcoming the difficulty of toning which some papers possess. The blue tone is certainly anything but agreeable; but the other pair of prints show that this may be modified by being stopped at an earlier stage. I am not fond of venturing upon explanations of things which happen in photography, but as I conceive that further experiments may encourage the use of nitric acid baths, I would invite discussion on the subject, by assuming that, as in the collodion process, a developer with nitric acid causes a deposit of silver in a more metallic state than one without; so in paper printing the salt of silver may be reduced in an analogous manner: if so, the gold would, I presume, be more readily and completely reduced. I requested the experiment before this to be borne in mind, and for this reason that that experiment was between faintly acid and faintly alkaline baths; and I showed that the former appeared to advantage, so that the evidence there was in the same direction as the subsequent experiment, where the nitric acid was present in still greater quantity.

Here are prints floated upon the standard bath, to which seven minims of glacial acetic acid were added for each ounce: the difference is not great, but those from the acid bath are of a redder tone.

I have now to speak of the toning quality of paper which has been kept sensitised for a considerable time, and this I illustrate by a part of the paper mentioned before as having been given me by Mr. Pyne. The sensitiveness, as I have stated, appeared, if not exalted, at any rate to be unimpaired; but the toning quality does not follow the same good example. Here is the illustration, by which you will see that the kept paper has hardly toned at all, while that which was freshly prepared (both having been in the solution for the same time) has arrived at a satisfactory colour. After removing them from the bath I was anxious to see whether the long-kept paper would tone by prolonged treatment; I therefore cut off a portion and replaced it in the bath, that portion in No. 3, and you will perceive that the brilliancy is completely destroyed: with but very little addition of colour, it has the pinky appearance of all prints which have remained in the toning bath too long.

Whether this experiment must be considered conclusive against long-kept papers is a matter for reasonable doubt; but I am inclined to believe that it must be so: for although, as I only had a quarter sheet, I could not repeat the experiment, I do not see how it would have affected the case had I been able to do so; and the only opinion to the contrary must be founded upon the supposition that it was one of those papers (and there are such) that will not tone. The time, however, that it was kept is far beyond that which would be required for any practical purpose; and if we admit, therefore, the loss of toning property we must not, without further trial, condemn an otherwise most useful assistant to the photographer. At our next meeting I hope to bring forward evidence that will settle this question.

When I offered this paper it was my intention to have carried it on through all the practical details of photographic printing, but since I have been engaged upon it I have found effects that ought to be satisfactorily determined before I proceeded to that length; and I have therefore resolved to wait until further experiments should enable me to speak confidently, not only on those heads which I have introduced this evening, but upon the equally important subject, the composition of the toning bath.

It would be useless for me to tell you simply that which has been published many times, and which you know. My desire is that the several branches of photographic printing should be thoroughly investigated. I have commenced with the nitrate bath in reference to the sensitiveness and toning quality it imparts; and although I do not now found any practical course upon my experiments, I have, perhaps, learned that which will enable me to do so at no distant period. I now give you the results of these experiments, incomplete as they may be, in the hope that they may be followed up by those who have the turn of mind, and that they may be brought to a satisfactory termination.

[The above paper was accompanied by more than fifty illustrative prints.]

THE FOTHERGILL PROCESS.

By Alfred Keene.

[Read at the Meeting of the Birmingham Photographic Society, April 24th, 1860.]

It is now about two years since the Rev. Mr. Law, when delivering an address to the members of your society, read a letter from myself detailing, as far as then known, the principles of a dry process just previously discovered by a gentleman staying in Leamington. This was the first public account of the one now popularly known as the Fothergill, so called after its discoverer.

Having recently published a pamphlet on the Fothergill process, on which I bestowed much labour, and expended information obtained by careful and diligent investigation, I will not tax your time and patience by repeating all the details there given; but, begging the acceptance by each member of a copy, I will pass its contents in review, accompanied with such remarks as have suggested themselves worthy of notice, and afterwards briefly enter upon the principles of the process, the effect on the sensitiveness by the use of different quantities of water for diluting the bath on the surface of the sensitised plate previous to the application of prepared albumen, the important influence a coating of albumen previous to that of collodion exercises, and a modification of the process suggested by the latter. This plan will, I think, enable me to bring within the limits of my paper an amount of information on the subject not previously presented in a collected form.

On referring to page 4 of the pamphlet, it will be observed that the operating room should be dry, free from dust, and have the temperature raised, if required, to not less than 54° F. The reason for the latter is mentioned, and the former I will give when treating of manipulation. The other remarks upon the operating room I will pass over, as also those relating to glass plates, collodion, bath solution, and prepared albumen—having nothing to add to the information there given—and proceed to manipulation.

It is on the manner in which manipulation is conducted that success or failure chiefly depends, whatever may be the plan adopted—a remark that holds good for every photographic process, on account of the essential tendency to a re-arrangement of chemical combinations; for, however carefully one part of the operation is performed, if the other is done carelessly, or the solutions, &c., necessary for various stages are allowed to come into contact at other times, failure is sure to be the result.

I would here direct your attention to the facilities the suspended shelf offers, not only in the preparation but also in the development of dry plates: by its use, the application of the solutions is much more under the control of the operator, and the necessity for so much handling of the plates during preparation is obviated, thus removing one rather prolific cause of stains. The only objection I can offer to it is a tendency of the wood, even when well seasoned, to warp after it has been some time in use. This would be obviated by substituting glass, roughed or painted, to prevent blocks, &c., slipping off.

Each modification of the process offers some peculiar advantage that the other does not possess, and very excellent results are to be obtained by any of those given; but my preference is still for No. 1, and particularly the method of applying the water, by holding the glass containing the requisite quantity near to the surface of the plate, commencing to pour on at the end nearest the operator, advancing as the wave proceeds to the opposite end (a gentle inclination being given to the plate for the purpose), that the water may fall on the deepest part of the wave only, and finishing as directed, by which risks of uneven sensitiveness is prevented. The water should be kept in motion fully the time mentioned, and finally made to flow over the edges the plate then drained for a few seconds only, and the prepared albumen applied as directed. If a longer time is given for draining, there will be some difficulty in making the albumen flow well up to the edges, which is an advisable operation, as it gives increased firmness to the film. All excess of the albumen must be washed away, or it forms a coating that prevents the action of the developer, and so practically injures the sensitiveness. The prepared albumen should always be filtered prior to use: when recently prepared, even if with two parts of water to one white of egg and the requisite quantity of ammonia, this is a somewhat tedious operation; but after it has been made a fortnight or three weeks, it readily passes through the circular filtering paper. Unless filtered, it is liable to produce small non-sensitive patches, somewhat similar to those from the use of collodion in which a portion of iodide is suspended, not completely dissolved.

The direction given to change the paper saturated with moisture on which the plates stand to drain, after about ten or fifteen minutes, and also that the latter be allowed to surface dry before it is film dried, should receive attention; for long-continued moisture favours a modification of the albumen and the silver compound with partial solution of the iodide of silver, which exhibits itself in various markings when the exposed plate is developed. The same or a similar change is also produced, but much more quickly, by the action of artificial heat on the moist prepared plate. This latter is easily illustrated by preparing a plate; but instead of placing it first to drain, putting it at once, collodion side uppermost, on a heated surface to dry. At that part where water last collected, one larger or several small transparent rings will be found, when dry, from which the yellow iodide has been completely dissolved. The necessity for these precautions applies most particularly to the cold and damp winter and early spring months. Mr. Standish, of Devonport, informs me that he suspends a piece of sea-weed in his room—a very good and simple plan for ascertaining whether the latter is in a fit state for preparing plates in: if the sea-weed remains very damp, it cannot be expected that evaporation will be sufficiently quick. The exposure and developing, I think, do not appear to call for any comment; and the same may be said of failures and their cause and remedy, which, with what has been already given, are fully treated of. I might mention one other remedy to prevent the film cracking and peeling off, viz., the passing along the extreme edge of the prepared plate, when dry, a little quick drying varnish. This completes the review of the pamphlet, and what we may term the Fothergill process proper.

(To be concluded in our next.)

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING PHOTOGRAPHIC COLLODION.

By T. F. Hardwich.

[Read at a meeting of the Blackheath Photographic Society, April 16, 1860.]

Although not a member of your Society, I have asked and obtained permission to read a paper this evening upon collodion, being fully convinced that the interests of the art require a better understanding of the modes used for preparing that substance, and also a more perfect agreement between the various formulæ. At present it is almost impossible to compare the experimental results of photographers, or to deduce any general principles from them, seeing that scarcely two can be found who agree in their mode of working. I propose, therefore, to lay before you for discussion an outline of what has been certainly ascertained as regards the manufacture of photographic collodion.

For a long time subsequent to the discovery of the collodion process by Archer the whole chemistry of the subject was imperfectly understood; and, even on the main question of the constitution of pyroxyline, opinions were divided. In 1854 Mr. Hadow published his researches, establishing beyond the possibility of a doubt the true nature of pyroxyline as a substitution compound, and proving the existence of at least four varieties of that substance, ranging from xyloidine up to gun-cotton; the lower compounds containing less, and the higher compounds more, of the peroxide of nitrogen. Besides these varieties, it was shown that the properties of photographic pyroxyline are much affected by the temperature at which it is prepared, and that the same acid gives a different result accordingly as it is used hot or cold.

Subsequent to this, Dr. Norris, of Birmingham, sent two communications—the one to the *Journal of the Photographic Society*, and the other to another photographic journal—in which he called attention to a point not before noticed, viz., the superior value in collodion of the substitution compound nearest to xyloidine, compared with that containing more peroxide of nitrogen, and approaching to gun-cotton in composition. This point may not, perhaps, at first appear of great importance, but, in reality, it is so; and any maker of collodion who chose to neglect it, would fail in producing a first-rate article.

Whilst these investigations were being carried on, many of the manufacturers of negative photographic collodion prepared pyroxyline from paper or linen, finding by experience that it was difficult, when using cotton wool, to secure that limpid character of collodion and intensity of image which the operator requires. The reasons why paper—described by chemical authorities as identical with cotton in its composition—should yet act differently in this process, need not engage much of our attention; it will be sufficient to state that the difference is probably due, in part, to the weakening which ensues when the nitric acid touches the outer portion of the fibre, and in part to the fact of paper being often made from cellulose in a semi-decomposed state, or from *linen*, which has been proved to yield a pyroxyline of different properties from that furnished by cotton.

My own experience, as a maker of collodion for three years, enables me to speak with confidence against the employment of any materials which give intensity to collodion in virtue of some principle of decomposition; for—to say nothing of the difficulty of obtaining these substances in a uniform state — it is certain that the stability of the collodion is lessened by their employment; just as nitroglucose, a product of the action of nitrosulphuric acid on sugar, is more unstable than pyroxyline, so is pyroxyline made out of old calico or linen more unstable than pyroxyline prepared, in the same acids, from cotton wool. Pictures of first-rate excellence have been taken with collodion from linen, but I cannot now recommend such collodion; for, on attempting to export it to distant climates, or subject it to great heat in our own country, it is apt to undergo a spontaneous decomposition, even when kept in the plain state in a dark place, and without any addition of iodiser. A knowledge of this uncertainty in some kinds of collodion is highly useful, because it prevents the maker from placing dependence on a formula which would eventually disappoint him. It is probable that photographers, trying such a formula, will be pleased with it; but let them send the plain collodion for a voyage round the world, and try to work with it again on its return, when they will probably find it in a gelatinous state, or in a state of semi-liquefaction, and so highly ozonised as to be useless for any purpose.

We are, therefore, bound to discard all unstable materials, and to return once more to the cotton wool, which must, by some means or other, be *coerced* into the proper state. That this could be done was, I believe, known many years ago to individuals; but, if so, it was not published. I have stated, on a previous occasion, that the process for making intense negative collodion from cotton wool was suggested to me, in the first instance, by the experiment of soaking paper in diluted sulphuric acid, and subsequently converting it into pyroxyline. The nature of the change produced by the sulphuric acid on the cellulose is not known; but it has the effect of increasing the intensity of collodion made from the resulting pyroxyline, and of imparting those qualities of negative which I have spoken of in connection with decomposed materials, like old cambric. Fortunately, the pyroxyline from the fibre parchmentised by oil of vitriol is more stable than that from linen, and has been proved to stand as well in collodion as most other kinds of pyroxyline which the photographer is accustomed to employ.

But, in addition to an action of the sulphuric acid in this process, I have lately succeeded in proving that a hot and weak nitric acid may also exert a very peculiar effect, and one which is almost exactly the reverse of that produced by the oil of vitriol. To show this action of weak nitric acid, three volumes of pure nitric acid of 1·45 may be mixed with a volume of oil of vitriol,* heated to 150°, and pyroxyline from the formula which I shall presently describe as No. 1, immersed in it for a few seconds. This treatment causes very little change in the appearance of the pyroxyline; but, when made into collodion, it is found to have lost its characteristic toughness, and to have become weak and rotten. Further than this, the negatives are no longer sharp and intense, but feeble and metallic in appearance.†

The above facts are of more importance, as regards the manufacture of photographic collodion, than would at first be supposed; for it can be proved that those actions which have just been attributed to sulphuric acid and weak nitric acid respectively, may be secured at will by modifying the composition of the nitrosulphuric acid. If a strongly-parchmentised product suitable for making intense collodion be desired, the bulk of diluted oil of vitriol in the mixture must be considerably greater than that of the diluted nitric acid; whilst, if it be required to prepare a porous collodion to remain a longer time without becoming surface-dry, and to yield an image with less violent contrast of light and shade, then the proportion of weak nitric acid may be increased. Observe, also, that these differences are not due to variations in the temperature, or in the degree of concentration of the nitrosulphuric acid, both of which are supposed to be the same.

The following table exhibits the composition of five different mixtures of sulphuric and nitric acid, in which an attempt has been made to graduate the proportion of water, so that the per-centage of peroxide of nitrogen imparted to immersed cotton fibre may be nearly the same in each. The table may not, perhaps, be absolutely correct, since it is very difficult to judge precisely of the strength of nitrosulphuric acid, on account of its solvent action on cotton varying not only with the temperature and quantity of water, but also with the quantity of diluted oil of vitriol present. The safest plan, therefore, appeared to be to neglect all theoretical calculations, and to construct the table by simple experiment, taking care in each case to work with the maximum quantity of water, and stopping the addition of water only when it was found that the product left a thick sediment on being dissolved in ether and alcohol. This plan will probably be found to answer for the three upper members of the series, and the two lower members are not of much practical importance.

COMPOSITION, BY VOLUME, OF NITROSULPHURIC ACID FOR PREPARING PHOTOGRAPHIC PYROXYLINE.

	Oil of Vitriol, 1·845 at 60 F.	Pure Nitric Acid, 1·45 at 60 F.	Water.
No. 1	3	1	$\frac{7}{8}$
No. 2	2	1	$\frac{5}{8}$
No. 3	1	1	$\frac{5}{16}$
No. 4	1	2	$\frac{5}{32}$
No. 5	1	3	0

* In attempting to produce this change by means of nitric acid alone, it will be found difficult to prevent the cotton from being dissolved. Pyroxyline is easily soluble in dilute nitric acid, but the addition of a little diluted sulphuric acid throws it down again, so that sulphuric acid in small quantity lessens the solvent action, independently of abstracting water.

† In addition to this modified pyroxyline produced by hot nitric acid mixed with a little sulphuric acid, I find that a remarkable change of properties may be produced by the pure nitric acid of 1·45 employed cold, and without any admixture of sulphuric acid. The pyroxyline gradually becomes opaque, and loses its solubility in ether and alcohol; eventually it dissolves in the cold nitric acid without any evolution of gas, and, if water be then added, opaque white flakes are thrown down, which, when treated with ether and alcohol, simply swell up without passing into solution.

The pyroxyline yielded by each of these five mixtures is soluble in glacial acetic acid, and also in boiling absolute alcohol; whilst in neither case does the resulting collodion produce an entirely opaque film. The substitution body formed is therefore a little above compound D or xyloidine, but not above compound C. A more careful examination, by immersing dry cotton at low temperatures, seems to indicate that if there be a difference, No. 1 is somewhat stronger than No. 5. The collodion, however, from No. 1 is more fluid than that from No. 5, thus showing that other causes, besides temperature and dilution of the mixture with water, have to do with flowing properties. A greater amount of fluidity than exists even in the collodion from No. 1 may be produced by dipping the pyroxyline first in No. 1, to secure the full action of the sulphuric acid, and afterwards in No. 5; the weak nitric acid will then act more decidedly than it would have done after a single immersion.

The temperature employed for the above table of acids may be 150° F.; and, in making the pyroxyline, we find that the lower numbers give a product which has an opaque appearance; whereas, the pyroxyline made by No. 1 and No. 2 exhibits no opacity. The five samples of collodion differ very much in the rapidity with which they set upon the glass, and also in their physical structure: the first setting rapidly and producing a horny film; the last scarcely possessing any power of setting. The only way of overcoming this, and putting them on something like a par, is by varying the proportions of ether and alcohol in the solvents, using more alcohol in the former, and more ether in the latter. These collodions also differ very materially as regards the intensity of the negative image, which increases as you ascend the scale.

These disjointed remarks have been thrown together, not with a view of exhausting the subject, but simply to assist in reconciling some of the extraordinary discrepancies in writings on collodion; for, whilst one author advises that at least three parts of alcohol be employed to one part of ether, another (a French author) says that the art of making good collodion is in reducing the alcohol to the lowest possible limits, and employing scarcely anything but ether. Others, again, have written as if all depended upon the iodising solution, and have distinguished between the quality of negative produced by iodide of potassium and iodide of ammonium, or between iodide of potassium simply, and the same compound containing iodide of silver dissolved. Not that I mean to affirm that the nature of the base is of no importance at all, because there are secondary reactions between the base and the pyroxyline, but simply that the particular iodide employed is of minor consequence as compared with the mode of making the pyroxyline.

The reasons which induced me to fix upon the formula for nitrosulphuric acid, marked No. 1 in the table, were principally as follow: I was assured by those who professed to be acquainted with the wants of the public, that a collodion was needed which would produce a dense negative in a rather dull light; for that the practitioners of the art in this country had to perform their work, as a rule, under great disadvantages in that respect, and it was comparatively easy to reduce the intensity when in excess, but more difficult to increase it when deficient. The highly-parchmentised pyroxyline appears to me to have an organic reaction towards the salts of silver somewhat greater than that of the other varieties, and I attribute the tendency to redness in the negatives to that cause. It has not been proved to be so, but the idea may be entertained, seeing that the action of diluted sulphuric acid is known to change cellulose into dextrine, and both dextrine and gum impart a red colour to a collodion negative when applied to the surface of the partially-washed film.

If we allow that great intensity of negative ought always to be at our command, yet there are other modes of obtaining it without purposely modifying the pyroxyline, and therefore the question becomes, which is the best? Glycyrrhizine was carefully tried, both in bath and collodion, but was condemned as delusive in the long run, although promising well in the beginning. Neither could confidence be placed in ether containing organic impurities, although I have heard it said that the cheaper and more highly-methylated qualities of ether, as they were made some years back, gave better and more intense negatives than pure ether. Rejecting both of these expedients as being uncertain, and also fatal to the integrity of the nitrate bath, it seemed preferable to produce the effect by modifying the pyroxyline, since this mode is found to injure the bath scarcely or not at all. Having adopted an intense pyroxyline, it is of the utmost importance to secure a pure ether; because, when the pyroxyline is of the organic kind, the ether must be free from organic impurity, or the collodion will be less sensitive, and the negative either too intense or highly solarised.

Granting for the moment that the question of pyroxyline is definitely settled,* there remains still an important matter to be considered in relation to photographic collodion. Are we to work with iodide only, or with mixed iodide and bromide? It seems certain that if bromide could be invariably used, we should at once emerge from many of those difficulties which now surround us; for the invisible image on the bromised collodion is of a comparatively stable kind, and is less affected in its development by those small disturbing causes which often upset, so to speak, the latent picture upon the simply iodised collodion, and cause it to present itself either with spots or comets, or a total reversed gradation of light and shade. During the past summer it was my endeavour, as far as possible, to encourage the trial of bromised collodions, and in most cases where the light was strong the result proved satisfactory. When, however, the image of the camera was imperfectly illuminated, the experiments were, with some few exceptions, reported as unsuccessful, and the pictures pronounced weak and ineffective, unless the negatives had been artificially strengthened by bichloride of mercury, or some analogous process.

In conclusion, I would venture to ask the members of the Blackheath Society to lend their aid in settling this important matter. The present time is the best, because the interest of photographers has been aroused, and an opportunity seems to offer of establishing the manufacture of collodion upon a secure and well-understood basis.

A FEW REMARKS ON AMATEUR PHOTOGRAPHY.

By F. Howard.

[Read at a Meeting of the South London Photographic Society, April 19, 1860.]

This subject has been placed before the photographic, and would-be photographic, public in a multiplicity of forms, as exhibited in the one shilling, three and sixpenny, and more expensive works; in highly polished mahogany and cabinet work; in the opticians' windows, and in some score of advertisements every week, all tending to show how easy one may commence the study, and how portable the apparatus is, and what a never-failing source of enjoyment the amateur may possess at the cost of a few pounds and a few lessons; how he can take portraits of friends, views of the charming scenes he may visit when holiday-making, as illustrated by specimens in the warehouse of the photographic chemist or apparatus-maker. But the only specimens produced by amateurs, in a majority of cases, are black fingers and spotted linen. Instructions as to how to proceed have been given so successfully that I am afraid no remarks of mine can point out the road more truly, or give a brighter picture of how to succeed, than can be obtained from the perusal of publications of moderate price. There will be little then said by me about the manipulating or processes, as indeed they have, and will, I hope, continue to form subjects for many papers amongst us; but what I am desirous of drawing the attention of amateurs and beginners to is, that there is another side to this picture, and that, in commencing photography, if you really intend to produce pictures, you must make up your mind for some hard work and vigorous study, and that it is not the easy pursuit some imagine to produce a good photograph. I will beg the favour of your attention for a moment, and ask you to reflect on the great attention which photography has received at the hands of amateurs. The many advertisements commencing "to amateur photographers"—the many distressed correspondents to the four Journals devoted to photography—show how much it is practised. Persons of leisure and scientific research have often followed such subjects as chemistry, electrotyping, magnetism, and sundry other delightful pursuits, and have added greatly to the store of knowledge now possessed on these subjects; but they bear no comparison to the number of amateur photographers. This cannot be from any greater ease or facility with which it is acquired, because I think there are few of those pursuits which cannot be mastered much easier than photography. It may seem strange that, though the successful pursuit of photography is attended with much greater difficulties than the various pursuits I have named, still it numbers many more followers. One would imagine the reverse to be the case; but the

* There are some points relating to the theory of pyroxyline for photography which it has been deemed advisable to omit on the present occasion, through fear of complicating the subject. For instance, an intense collodion may be made from pyroxyline prepared without any excess of sulphuric acid, if the amount of water be diminished, and the temperature raised sufficiently to disintegrate the fibre (a little chlorine in the nitric acid will assist in this disintegration). This material, however, appears less stable than the other, and, when examined, is found to contain a bitter product of decomposition in some quantity. Probably the acids convert a portion of the cellulose into grape sugar, which, when acted on by nitric acid of a certain strength, forms nitroglucose. The experience of the author is unfavourable to the employment of this pyroxyline in photography.

great secret is that the results, when arrived at, are much more pleasing; they offer enjoyment not only to the amateur who, wrapt up in any pursuit, is delighted at the results, but to friends, acquaintances, and everybody who inspects them. You arrive at results which the most accomplished artist could never produce, and you find yourself in possession of a source of infinite amusement and instruction, with which can be combined healthful exercise with close study and research; and from the multiplicity and varied features of its application, a never-failing source of employment for the leisure hour. But with all these incentives, the successful pursuit necessitates a constant attention to the subject; because I consider him no true amateur who does not follow his art closely, watching every change and improvement, and ready to avail himself of them, and to increase his knowledge on the subject. This involves, for the amateur, far more attention and painstaking than, I am afraid, many feel disposed to give. I think we should see much better photographs than are now sometimes seen as amateur productions, if they were not satisfied with average results. That the most successful results can be arrived at I am certain. It does not do to be satisfied with average results, and plead that you are only an amateur: if determined to produce pictures, do insure their being creditable. The reminiscence of a tour in the country, the portrait of a friend, the copy of a print, will be much deteriorated in value if compelled to be prefaced by the apology, "I am only an amateur," instead of trying again for a better. It has been said that if we would only see our faults, we are in a fair way of correcting them; and I would especially encourage and recommend amateurs to compare their productions with those of the best professional photographers—to say to themselves candidly, "This is a bad photograph, I must try again," instead of putting it among their collection, and saying, "It is pretty well for an amateur." Besides, amateurs seem likely from their number to form a large proportion of the public, whose admiration is alike an incentive to the exertions of first-class photographers and a corrective to the inferior productions of which, alas! we see so many. I think that amateurs can do much in this matter; and a higher standard will be demanded, if amateurs, by ignoring their indifferent productions, place before their friends good specimens, and show them that photography can produce something to admire.

Gentlemen of leisure I would advise to make themselves masters of the art theoretically and practically: they have a chance of becoming something more than successful operators, as has been facetiously observed in alluding to the mass of photographers. If experimentalists, persons of leisure may achieve great success, and confer great boons on their less fortunate brethren; for I do not think there is a wider field than that open to the experimental amateur photographer. There is much to be discovered and improved upon, always remembering that they are themselves greatly indebted to what may be called the fathers of the art, for their liberality in giving their discoveries to the world.

And as regards the successful operators, there is a wide field for them also. By-the-by, an amateur may think himself very fortunate if he can be classed with the successful operators. It is no easy thing to accomplish this successful operation; for though you may not make your own collodion (which Mr. Seely, the American, says is a capital receipt for spoiling a suit of clothes), and may not be so well up in the chemistry of the art as you may desire, you must have a deal of perseverance to become even an operator; and I contend you are none the less a photographer, as I have observed, I think, in this room before, that it does not detract from the artist's talent, or make him less an artist, because he does not compound his own colours. A good operator is likewise absolutely necessary for good chemicals to be appreciated. It may be all very well for the photographic chemist or manufacturer of collodion to tell you this or that will answer admirably: I would rather have the opinion of a good operator as to its merits.

Pardon a little digression. What the distinction is between photographer or photographist and operator I cannot understand; but a distinction is made I believe. The person who prepares the plate, sensitises and develops, is called the operator, and the person who exposes is called the photographer, and calls himself artist—a misnomer evidently. My interpretation of artist does not apply to any photographer: it is impossible to apply to that which is produced by a careful attention to certain chemical laws the same title as you would to the production of the hand and brain of a clever man, and to call the producer of either an artist indiscriminately, and sell both productions by the square inch. I merely allude to this vexed question because I think there ought to be no distinction in the term photographer, except as photographic chemist, apparatus maker, experimentalist, and working photographer. If there is any claim to the title of artist from the exposing portion of the work, I think all amateurs ought to claim the title at once, as having not only to expose, but excite, develop, and perform all the disagreeable adjuncts of plate-cleaning, &c.

(To be concluded in our next.)

ON FIXING POSITIVE PROOFS.

By MM. Davanne and Girard.

(Continued from page 114.)

Our previous experiments have already established that, after a suitable fixing, the proof is formed of two different substances, mixed in variable proportions—metallic silver and the argento-organic compounds. It is these, and these only, that constitute the coloured parts of the proof; therefore it is upon them that the ordinary re-agents, after having fixed the proof, can exercise a subsequent destructive action.

Setting out from this fact, we propose to examine whether, independently of every accessory circumstance, the fixing agents can exercise a dissolving action upon these two substances. With this object we have, on the one hand, prepared some metallic silver by reducing the chloride by light alone; and, on the other, some argento-organic matter, by placing in similar circumstances a solution of starch containing chloride of silver in suspension. After the action of the light the precipitates thus obtained were fixed. Thus fixed, they were placed in solution of cyanide of potassium, of two per cent. strength, in concentrated ammonia solution, and in hypo of ten per cent.; then, after the lapse of various periods of time, we have examined the supernatant solutions for the presence of silver. Operating in this manner, we observed very important differences in their mode of action.

First, as to cyanide of potassium. This re-agent attacks and dissolves metallic silver as well as the argento-organic compound, but it acts much quicker upon the first than upon the second. After one day's contact, the solution covering the metallic silver already contained notable quantities of this metal; the solution that covered the argento-organic compound also contained some of it, but in a smaller quantity, and only at the end of two or three days did the result obtained with this latter equal that furnished by the first. These facts, observed under clear and precise conditions, lead us to understand why we cannot employ the energetic solvent properties of cyanide of potassium in positive printing. This agent fixes rapidly and well, but its action upon the coloured portions requires too much care and precaution,—it is in fact a dangerous re-agent.

The action exercised by ammonia is entirely different. We have already remarked upon the peculiar colouration which, by a dyeing phenomenon, this re-agent communicates to the argento-organic compound; but there is another point of view, extremely important in practice, to which we must call attention. When we leave silver, the argento-organic compound for instance, in contact with strong ammonia, we perceive, even after eight days of contact, that the ammonia has not removed the slightest traces of silver from either, by which we may conclude that ammonia does not dissolve the coloured portions of the proof; but, at the same time, a curious phenomenon exhibits itself, for whatever the care taken, the ammonia solution above the two precipitates does not become clear, but remains constantly opaline, and appears to hold in suspension an almost imperceptible yellow precipitate, as if dissolving at first a small quantity of silver, the ammonia immediately deposited it in a state of ammoniacal combination. From this follows the explanation of the influence that fixing by ammonia exercises upon the whites of the proof, in communicating a light yellow tint to them. We may, in fact, attribute it to the formation of this yellow precipitate which we have constantly observed in the supernatant ammoniacal solution, both of metallic silver and the argento-organic compound. At the moment when the proof is plunged into the ammonia, the iron-coloured parts are rapidly dissolved; but if the sojourn be prolonged, an action is set up between the coloured film and the alkali, an action which is shown by the formation of a precipitate which is deposited equally all over the proof.

As for the fresh hyposulphite of soda, it acts upon the coloured parts of the proof, not like ammonia, but in the same manner as cyanide of potassium. Put in contact, in a state of solution, with the silver and the argento-organic matter, it ultimately attacks and partially dissolves both, only, as the daily experience of photographers proves, it acts with much less energy than diluted cyanide. Still its action is very evident, and indicates, *a priori*, for every fixing compound, the necessity of not leaving the proofs

too long in the fixing bath. We shall take care, in a subsequent chapter, to state approximatively the time necessary for fixing with solutions of hypo, of various degrees of strength.

To sum up what has been stated, we say, that cyanide of potassium, even when diluted, rapidly removes the coloured portions of the proof. Ammonia does not dissolve them, but, at the end of a certain time, this alkali, by means of a silver compound, tints the white of the proofs yellow: the hyposulphite of soda attacks the coloured parts of the proof, but only after the lapse of considerable time.

Such are the chief facts which we have been able to recognise by means of our researches upon the action of the fixing agent upon the proof. We shall next group them together, and endeavour to deduce results by which a surer and more rational method of fixing may be established.

(To be continued.)

DOUBLE CHLORIDES OF GOLD AND POTASSIUM AND GOLD AND SODIUM.

By M. Fordos.

In a mixture of one hundred parts of nitric acid and four hundred parts of hydrochloric acid dissolve one hundred parts of pure gold. Evaporate the solution so as to obtain hydrochlorate of the chloride; then add fifty-one parts of bicarbonate of potassa in distilled water, and evaporate to dryness; then expose to a gentle heat, to drive off the excess of acid, and dissolve the dried product in distilled water. Filter the solution through asbestos or powdered glass, and evaporate the liquid to obtain crystals. These consist of one equivalent of perchloride of gold, one equivalent of chloride of potassium, and five equivalents of water—

$$Au\,Cl_3,\,K\,Cl + 5\,H\,O.$$

Chloride of gold and sodium is prepared in the same manner, substituting ninety-three parts of carbonate of soda for the fifty-one parts of bicarbonate of potassa. Its formula is —

$$Au\,Cl_3,\,Na\,Cl + 4\,H\,O.$$

NOTICES OF RECENTLY PUBLISHED STEREOGRAPHS.

Fountains Abbey.

W. Woodward, Nottingham.

There are but few people who do not feel some sort of interest in connexion with the ruined edifices of former days, even if they are nothing more than mere heaps of rubbish. To what speculations do they not give rise! What an array of pleasant associations do they not leave in our memories! But if instead of mere shapeless heaps we have arches and towers, buttresses and mullions, sculpture and tracery in sufficient abundance just to indicate the glories that have been, without too clearly defining what may possibly have been wanting, while the rugged features, traced by the destroying hand of time, are clothed with a graceful veil of verdant ivy and modest creepers, then indeed we fairly slacken the reins of imagination, and let it revel in unshackled freedom.

Perhaps one of the peculiar charms attendant on a visit to some celebrated monument of antiquity may be found in noticing its effect upon our companions — how one is engrossed by the archæological features, another has an eye solely to the picturesque, a third poetises and peoples the now vacant tenement with phantoms of its fancied former occupants; then there are the pleasant ramble and scramble, with the thousand little surprises, the bright sunshine and murmuring breeze — (who would visit a ruin in bad weather?) — the high spirits, and, perchance, the ringing laughter of musical voices. To how many such "green spots in memory's waste" may not a visit to Fountains Abbey have given rise! We have never been fortunate enough to tread the mossy turf of that charming spot, yet we have wandered there in spirit by the aid of those twin-sister fairies, named respectively Camera and Stereoscope, and perhaps we have been enabled to carry away a more vivid recollection of the local beauties than some who have visited them in the body: who knows? But, be that so or not, of this we are quite sure, that those who have been visitors will certainly be delighted to possess the pleasing series of transcripts before us to brighten up their impressions, while those who have not been so favoured will be equally glad to have a chance of becoming acquainted with the charms of this renowned spot.

Mr. Woodward has laid before us Fountains Abbey in many aspects — views from east, west, north, and south, near and distant, in sunshine and in shade, nave, choir, gateway, aisle, turret—all are here, and all are charming, though as photographs some are certainly better than others.—In the Nave and Choir (No. 118), the effect is marred, to some extent, by the distortion arising from the lens employed; but in No. 116, the Gateway of the Eleemosynary Chapel, and No. 122, The Bridge leading to the same, no such defect is apparent, and both are highly pleasing subjects, apart even from any association, and are treated in an artistic manner.—The Bridge over the Skell (No. 121), which forms a part of the series, is also a beautifully-executed production.— Of the remainder we will mention No. 111, South-east View from De Grey's Walk, as presenting perhaps the most pleasing general view of the ruin, and No. 110, A South View from the same spot. Of this last we have two specimens, the point of view in each differing but a few yards from the other, yet the aspect is wonderfully different. The fact is, that by a little careful inspection we perceive that one copy must have been taken in the morning and the other in the afternoon, and consequently the shadows are thrown totally in opposite directions. Both specimens are good, but that taken in the afternoon is decidedly the most pleasing, not only on account of the direction of the shadows, but the slight variation in the point of delineation has introduced the trunk of an old tree, which materially heightens the effect.

Mr. Woodward is an industrious and skilful operator, and his works deserve an extended circulation.

THE "LIVERPOOL ALBION" ON PHOTOGRAPHY AND THE FINE ARTS.

A Critic, according to the strict definition of the term, is a person who *can judge*, and consequently "who takes upon himself to censure others' works." He who is no judge can be no critic, and the censure or praise of such a person will therefore be equally valueless. We read of a judge who decided all causes by the throwing of dice, but no one upholds the justice of his decisions, summary as they undoubtedly were; and no one, I opine, would think the exposure of such an unauthorised arbitrator undeserving notice. This is my plea for a little of the valuable space of The British Journal of Photography.

Speaking of the photographs now exhibiting at the Exhibition of Fine Arts in Liverpool, a critic in the *Liverpool Albion* says:—"The value of these, however, *are* not only independent of, but wholly at variance with, the fine arts. They are records of facts conveying the testimony of their truth in themselves. But the fine arts consist in the application of these facts to elicit higher feelings or emotions, and in this photography has hitherto entirely failed." And he adds, "The only use of exhibiting such things with pictures and drawings is the chance that they may, by comparison, instruct the people in the difference between nature and art." Thus with portentous wisdom enthroned upon the knitted brows, with hand outstretched and palm turned outward, the sage hath spoken, "as who should say, I am Sir Oracle, and when I ope *my* lips let no dog bark."

Now, although the imitation of nature will always be subservient to the more intellectual qualities of art, I have yet to learn that the fact is "independent of, and wholly at variance with, the fine arts." I have yet to learn that the loftier emotions of the mind may not answer the call of truth as readily as that of any art called "fine." And I cannot believe that the faithful imitation of nature in her most picturesque and poetical aspects does not constitute a fine art, simply because the mechanical aids employed are neither brushes and colours nor pencils.

As a fitting comment upon this piece of unqualified and unsupported criticism, permit me to repeat an oft-told anecdote.

The mighty emperor of China, and of nearly all the rest of the universe, brother to the sun, cousin to the fixed stars, and near connection of that very influential relative, the moon, desired a picture of a new street in his capital, and commissioned a certain European painter, then in his neighbourhood, to paint the same. The artist did his best, and on the day appointed brought the production to the celestial court. Of course it was executed with due regard for the rules of linear and ærial perspective, and in the eye of the artist was therefore a good record of a fact "conveying the testimony of its truth" in itself. So with anxiously beating heart he uncovered the painting, that the radiance of the divinely royal optics might fall upon it: as they did so, the emperor started to his feet, struck dumb with astonishment. "It is the street itself!" at last gasped the astounded sovereign. "It *is* the street itself!" murmured the amazed courtiers. Then the artist breathed freely, and glowing visions of wealth, rank, and honour flitted before his imagination; but — "Let that presumptuous barbarian deceiver be instantly bastinadoed!" cried the emperor, turning a glance of annihilating wrath upon the horrified artist. "We commanded him to produce *a picture* of the street, and behold! he hath produced the street itself! we swear we could walk down it! Away with him! but let the thing he made be preserved for its only use, namely, that it may, 'by comparison, instruct the people in the difference between nature and art.'"

To return to our oracular critic. We next find him asserting that "Photography, though valuable as an aid to science, and, so far as it can preserve a record of appearances, subsidiary to fine art as saving the trouble to an artist of making sketches, is not a fine art, and never can be made so!" Some irreverent folk will ask Sir Oracle, "Why not?" And so they may, for Sir Oracle hath said his say, and "there's an end

on't." Photography "is not a fine art," says he, and of course it is not. Photography "*never will be a fine art*," says he, and of course it never will be!

I once before had occasion to remark that the cause of art is at enmity with such worthies as resemble our Liverpool art critic. Their fanciful and frivolous distinctions, their mystical rhapsodies, their loose talk about the ideal, abstract ideas, &c., have so confused and befogged the mind upon all matters connected with art, that it is but small wonder when we find that the public are more thoroughly ignorant of art than of any other subject of a character equally popular. Permit me also to remind you that, in the paper already referred to, I boldly stated that light plays much the same part in photography that pencils do in drawing, and that photographs are produced by the camera and lens in exactly the same sense as paintings are produced by paint and brushes; that bad photographs, however numerous they may be, are not conclusive proofs against the possibility of producing good ones, any more than inartistic paintings are evidence against the possibility of paintings being artistic. I know very well that artists of repute have subscribed to the opinion of the Chinese Emperor (and said, in the words of an eminent lecturer upon art, "*Painting is, strictly speaking, no imitation at all of external nature*"): but their works have eloquently and forcibly denied their words; and the only painters who really seem to subscribe to this doctrine are the pre-Raphaelites denounced by our oracle, whose works *really* are "no imitation at all of external nature." I might point out the impossibility of depicting abstract ideas, and show how idealising is only a different mode of imitation; how imagination will make pictures in the clouds, the burning coals, and the changeful shadows, which yet exist neither in the clouds, the fire, or the shadows. I might dwell upon natural beauties whose faithful and perfect imitations would contain more poetry, more sublimity, more associated ideas of love, tenderness, admiration, religious veneration, sympathy, and pity, than Sir Oracle would listen to (for fear he might be convinced); but, instead of that, I will turn to our photographers, and earnestly call upon them to regard photography, not as a chemical or optical study only, but as *a fine art*. If they will only do this their productions will give a gloriously triumphant denial to the carping critics who so dogmatically denounce, and would fain degrade, our beautiful but infant art. ALFRED. H. WALL.

Meetings of Societies.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

On Monday, the 16th ult., the Annual General Meeting of the Blackheath Photographic Society was held at the Golf Club-house,—the President, J. Glaisher, F.R.S., in the chair.

After the minutes of the previous meeting had been read and confirmed, Messrs. C. Busk and H. Williams were appointed auditors.

In consequence of the resignation of Mr. J. B. Spencer, as Treasurer, a motion was moved, and carried unanimously, requesting the joint Secretaries, Messrs. T. R. Wheeler and Travers B. Wire, to act also as treasurers. To effect this change, the bye-law bearing on the office was altered accordingly.

After the usual vote of thanks to the Secretaries for their services during the year, the Report of the Council was read, adopted, and ordered to be printed for circulation among the members.

Mr. Glaisher, the President of the Society, in conformity with the bye-law, retired from his office, and, on a ballot being taken, Mr. Heisch, F.C.S., was chosen to succeed Mr. Glaisher in the office of president. The following resolution was then moved by Mr. J. Harding, seconded by Mr. H. Williams, and carried *nem. con.*:—"That the best thanks of this Society be tendered to J. Glaisher, Esq., for his able, impartial, and conciliatory conduct, while in occupation of the chair of this Society."

Mr. Glaisher, having made a suitable response, vacated the chair in favour of his successor.

Mr. Heisch, on taking the chair, made a few brief remarks to the members, and then called on Mr. T. F. Hardwich to read his paper *On the Present State of our Knowledge Regarding Photographic Collodion.* [See page 130].

When Mr. Hardwich had concluded his paper,

The President (Mr. Heisch) spoke as follows:—I have listened with great pleasure to Mr. Hardwich's communication, and while cordially agreeing with much that he has said, there are still one or two points on which my experience has led me to slightly different conclusions. I am not altogether prepared to discard the use of paper as a material for the manufacture of collodion, as I believe that there are certain properties possessed by such collodion which cannot be secured by the use of cotton. I believe that a greater weight of pyroxyline may be dissolved in a given quantity of ether or alcohol, and still run well, when we use paper than when we use cotton, and this is often of importance. I have not found collodion thus prepared more subject to decomposition than any other, if proper care be taken to secure pure ether and alcohol. During the heat of last summer, my dark room was for a long time at a temperature of 96°, and in that room I kept and used the collodion, not only for wet but for dry plates, and got on perfectly well, while many of my friends using the same process with other collodion, were brought up by the heat, and could not use their plates. I have still by me collodion prepared eighteen months ago, and it shows no signs of spoiling. I do not mean to say I should recommend collodion such as I am now speaking of for all purposes; indeed, I fear it is impossible to obtain any collodion which will suit the requirements of all photographers, the circumstances under which they work being so different. Thus, a collodion admirably adapted for portraiture in a glass house, is hardly that which one would choose for copying new stone buildings in a bright sunlight, nor that again, the same as for dark foliage; and it is a question if the requisite differences can be obtained with one pyroxyline by variations of solvents or iodisers, or if it will not be found necessary to vary the pyroxyline itself. The purposes for which I chiefly employ collodion are such as do not require any great amount of sensibility, but rather the capability of standing considerable exposure without solarising, so that the bottoms of deep holes of different colours may be brought out before the lighter portions are burnt up. The pyroxyline I employ is prepared with

* Nitric acid, sp. gr. 1430	39 parts.
Sulphuric acid	31 „

Swedish filtering paper is soaked in this for one hour, at a temperature first of 130° to 135°, and allowed gradually to cool, keeping it well shaken for the first ten minutes, to bring fresh portions of acid constantly in contact with the paper. The solvent is ether five parts, and absolute alcohol three parts, including that in which the iodides are dissolved. For very large plates I should use six grains of pyroxyline to one ounce of the solvent; for anything up to ten and eight inches, eight grains. This collodion, besides its non-liability to solarisation, is remarkably well adapted for dry processes, losing its sensibility less in drying than most. I have recently tried with this another collodion iodised precisely in the same way, though the latter worked in one-third of the time when wet: after drying, it required nearly double the time requisite with my collodion. With regard to the question of bromides in collodion, the Society are aware that I have devoted much attention to the subject. I am not prepared to advise their use on all occasions, more particularly for portraiture: in landscape collodion, I think them always useful. I see no reason to doubt the truth of what I stated to the Society on a former occasion, that they should be used in atomic proportions: for subjects in which greens predominate, two atoms of iodide to one of bromide I still believe to be the best; indeed, I should take this as a general landscape collodion. I may mention, as confirming this view, that, since I first published this formula in 1852, several others, uninfluenced by theoretical considerations, but simply going on adding bromide till the best working point was reached, have published formulæ in which the bromide and iodide are precisely in the proportions above mentioned. For reds and yellows, I believe the proportion of bromide may be advantageously increased. Our late president, Mr. Glaisher, finds that for artificial light, in which the yellow is very predominant, two atoms of bromide to one atom of iodide give the best results. This formula was also arrived at purely experimentally. When, some time ago, Mr. Hardwich spoke on this subject, he thought I had recommended too large a proportion of bromide. I observe in his last formula he has much increased the quantity he first employed, and I am not without hopes of ultimately converting him to the "atomic theory" as applied to this subject.

After a cordial vote of thanks to Mr. Hardwich for his admirable paper, Mr. Vernon Heath was elected a member of the Society, and the meeting was then adjourned to the 21st instant.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of the above Association was held at Myddleton Hall, Islington, on Wednesday last, the 25th ult. George Shadbolt, V.P., occupied the chair.

Mr. George Dawson read a paper *On the Reaction of the Chloride of Silver upon the Hyposulphite of Soda.* [See page 127].

In consequence of a press of matter the report of the discussion on Mr. Dawson's paper is deferred till our next number.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual monthly meeting was held on the 19th instant, in the Lecture Hall, Walworth,—the Rev. F. F. Statham, B.A., F.G.S., President, in the chair.

The minutes of the last meeting having been read and confirmed,

The Secretary read the following rules, drawn up by the committee, for the regulation of the Exchange Club:—

1.—That a Secretary be appointed by the Committee to negotiate all exchanges between members and non-members of the Society, in order that an equitable arrangement may be secured.

2.—That gentlemen and ladies be eligible for membership, whether members of the Society or not; and that no form of introduction be necessary beyond that of placing in the Society's folio a specimen print, with the name, address, and the words "for exchange" attached.

3.—That all communications relative to the business of this Exchange Club be prepaid, and stamps enclosed for replies.

4.—That a list of members, and a description of such specimens as are provided for exchange, be published quarterly; and that no alteration be made in these Rules save at a special meeting, convened by at least one-third of the members.

Mr. Hannaford having kindly consented to act as Secretary to the Exchange Club, communications may be addressed to him at 6, South Grove West, Mildmay Park, Stoke Newington, N.

* The acid I employ is that called "acid nitros," of sp. gr. 1420, or thereabouts, made up to sp. gr. 1430, with pure nitric acid of sp. gr. 1500. I find this gives better results than acid which contains more of the lower oxides of nitrogen.

Mr. Wall placed his own name, that of Mr. F. Howard, and Mr. Leake, jun., down as members.

It was then stated that several members of the committee, and others of the Society, had discussed the possibility and propriety of dispensing with the usual three months' recess, and holding meetings in the open air, within a few miles of town, so that they might put the knowledge acquired at such meetings as the present into practice; give the beginner among their members an opportunity of working side by side with professional operators and experienced amateurs, and strengthen the social harmony which then, happily, so closely united their little community. These open-air meetings would, he had no doubt, also tend to advance the art of photography; and, as ladies would be enabled to accompany the members, the pleasure derived would be considerably enhanced. It was suggested that such meetings should be held upon the third Saturday in each month, commencing in July. A somewhat similar meeting (a sketch of which appeared in the last number of The British Journal of Photography) had been held in Epping Forest, at which Messrs. Wall, Hannaford, Howard, Simpson, Hearle, Leake, Cotton, and others had been present, and the success of that experiment augured favourably for its repetition. They were accompanied by ladies upon this occasion, and he, the Secretary, could assure the members (despite Mr. Shadbolt's sly comment) that their presence in nowise retarded the business of that which was one of the most pleasant of pleasant days.

Upon the motion of Mr. Hannaford, it was agreed that the next meeting should be made special, to effect the requisite alteration in the rules of the Society.

Seven stereographs, by Messrs. Wall and Leake, were presented for the folio. These had been taken upon the occasion above referred to, and the President pointed out a group called *The Earliest Pic-Nic of the Season*, which he thought fully illustrated the Secretary's remarks, and showed how useful a few ladies might be made in giving fresh charms to the landscapes, or adding character to the scenes depicted.

An excellent adaptation of the alabastrine process was illustrated by a very beautiful specimen, presented by N. E. Fitch, Esq.

The Secretary also presented a print from a panoramic negative, taken by Mr. Sutton. He was of opinion that the Parent Society had scarcely done justice to this invention, and said, although conscious that little boys should hesitate before they found fault with their papas, they must pardon him for adding that, whatever the practical utility of this panoramic lens and camera might be, it was certainly of a character which should ensure respectful attention from a body of gentlemen assuming the office of judges. Had he been present, he should probably have reminded one or two of the members of that Society that Mr. Sutton's invention, and not Mr. Sutton's peculiarities, was the subject of discussion, and that the substitution of ridicule for argument was not consistent with either good taste or sound sense.

Mr. Howard then read a paper, entitled *A Few Remarks on Amateur Photography* [see page 131], showing, as amateur productions, some dozens of excellent stereographs.—On the conclusion of the reading of the paper,

The Chairman complimented Mr. Howard upon his honesty of purpose in not disguising the many real difficulties in the way of all beginners, and urging them to aim at the higher excellencies of the art. But it should be remembered that even our most successful professionals were once amateurs, and owed their eminence solely to courage and perseverance.

The usual vote of thanks was then warmly accorded.

Mr. Wall thought the glove had been thrown down to him by Mr. Howard, as that gentleman knew that he always held the real photographer to be also an artist. He (Mr. Wall) saw productions at the last Photographic Exhibition that were unmistakably pictures, and owed their superiority not to extra mechanical skill, or great chemical acquirements, but to "the hand and brain of a clever man." He had so recently expressed his opinions upon this subject he would not fatigue the members by their repetition, but content himself by adding, that however deficient in artistic qualities the great mass of photographic productions might *now* be, he was certain that they were not necessarily so.

Mr. Hannaford said that when the photographer was also an artist, his productions were pictures, although few photographs deserved the title of artistic. The photographer who had no knowledge of art planted his camera almost at random, and was dependent upon mere chance for the results; but this was not the case with the artist. Mr. Hannaford here took up several of the photographs exhibited, and pointed out their sins against the artistic (one of which Mr. Martin entitled *The Picture of a Post*, such an object occupying the most conspicuous and important position in the view). Referring to the power a photographer possessed of making pictures, Mr. Hannaford said this power was increased when a greater angle was secured, as was the case with the new panoramic lens (a statement which he illustrated with some remarks upon the print Mr. Wall had presented), and then proceeded to touch upon the question of photography in the early morning, and the use of river, rain, and distilled water, concluding by thanking Mr. Howard for his excellent paper.

Mr. Howard, in reply, said he of course knew that the claim of a photographer to the title of artist was a vexed question, but he was not competent to decide it. The subject of water, he thought, should be treated with discretion. He always used distilled, and recommended others to do the same; and, with regard to the possibility of producing pictures at five o'clock in the morning, he begged to submit some so taken to the inspection of the members.

Mr. Simpson said he also should recommend the use of distilled water, and that extreme care in every branch of the process advocated by Mr. Howard, if only for this reason, viz., that such carefulness limited the field which in case of failures would have to be traversed for their causes.

Mr. Howard thought extreme carelessness seemed to be characteristic of some operators, and by way of instance referred to a comical letter which appeared in the last number of The British Journal of Photography, signed "Israel Holdsworth."

Mr. Simpson remarked that when a man of such a stamp said he had no failures it was more than probable that less partial judges would say he had no successes. That correspondent, however, was very logical: he not only asserted that "a deal of nonsense is written," but accompanied the assertion with a most conclusive proof of the fact.

Mr. Thomas Clarke next detailed a series of experiments, intended to demonstrate that a film containing a simple iodide, without free nitrate or any other salt of silver, was just as sensitive as when the before mentioned conditions had been complied with; and afterwards gave the following as the results of some experiments with the alkaline silver bath:—

1. Forty grains, rendered alkaline with NH_3, gave foggy pictures.
2. Thirty grains, rendered alkaline with NH_3, at times clear pictures.
3. Forty grains, render alkaline with NaO, CO_2, at times slightly foggy.
4. Thirty grains, rendered alkaline with NaO, CO_2, produced perfectly clear pictures.

The President would not pretend to offer any remarks upon the value of Mr. Clarke's experiments; but, in performing such, that gentleman had given the members a very excellent example, and deserved their thanks.

A vote of thanks was then awarded to Mr. T. Clarke.

Mr. Simpson inquired if Mr. Clarke had manufactured the collodion he had used in his experiments, or knew its character, because the whole question hinged on the point as to whether the collodion contained a simple iodide or a bromide also.

Mr. Clarke had merely purchased the collodion, and therefore could not answer Mr. Simpson. It was, however, procured from Messrs. Horne and Thornthwaite's.

Mr. Leake had never himself succeeded in procuring a good picture with an alkaline silver bath.

Mr. Hannaford affirmed that if free silver were removed from the plate, as described by Mr. Clarke, a very great increase in the time of exposure would be required to obtain even the trace of a picture.

Mr. Howard must certainly agree with the remarks made by Mr. Hannaford. Learning from the Secretary the nature of Mr. Clarke's experiments he had repeated them, and the results were such as he (Mr. Hannaford) described.

Mr. Martin said, in a film containing two salts of silver, when the free nitrate was removed, the plate was insensitive to light; and instanced the collodio-albumen process, in which the free silver was removed by iodide of potassium.

Mr. Leake named the Talbotype process also.

Mr. Martin said in that case a single iodide was used; in the other the collodion contained both an iodide and a bromide, thus forming in the excited film two salts of silver.

Mr. Hannaford thought Mr. Martin had overlooked the fact, that in the case of the collodio-albumen they obtained in the insensitive state of the plate the *white* iodide of silver, on which light had little or no effect. That was afterwards converted into the yellow or sensitive iodide by re-immersion in the nitrate of silver bath. Dr. Hill Norris had stated, in a paper read last year at a meeting of the North London Society, that he believed these two salts were chemically different.

Mr. Ackland stated that he had taken a "Hill Norris" prepared plate, exposed it to light, and then treated it as though it were simply a clean plate. He afterwards prepared it by the Fothergill process, exposed again, and, on developing, found the picture perfect, permeating both films. Here the exciting had restored the first film to its state of sensitiveness.

Mr. Hannaford said, if they sensitised, exposed to light, and then collodionised, the plate would evidently be rendered insensitive, exactly as in the collodio-albumen process—the iodide in the collodion acting in the same manner as the iodised albumen.

Mr. Simpson remarked that the old daguerreotypists were in the habit of restoring a plate, the sensitiveness of which had been lost by exposure, by placing it again over the iodine.

Mr. Martin said, beyond question, there was no excess of the silver salt in the formation of the iodide.

Mr. Leake remarked that the fumes of acetic acid had been said to restore sensitiveness.

The discussion then grew very animated, and

Mr. Martin remarked upon the attempts made in scientific works to draw such extremely nice distinctions, more especially in reference to what is called the allotropic condition. As an instance of the changes in colour effected by molecular disturbance, he stated that on mixing mercury and iodine in the proportion to form biniodide of mercury, and submitting to a certain sufficient temperature, crystals condensed in the cool part of the tube, which, while hot, were bright yellow, but on cooling assumed a brilliant scarlet colour. If the same elements be combined in the proportion to form iodide of mercury, and the mixture be treated in a similar manner, the crystals which condensed in the cooler position of the tube were scarlet while hot, and yellow when cold. If both of these

be examined while cooling by a magnifying glass, a change of crystalline form would be found taking place, illustrating very aptly that molecular arrangement would cause or determine colour; *ergo*, molecular arrangement *might* determine colour in iodide of silver precipitated in excess of nitrate or iodide.

Mr. Hannaford regretted that no satisfactory solution of the chemistry of the Daguerrean process had been arrived at.

The discussion then turned upon that subject, Mr. Martin suggesting that some attention should be given to certain experiments illustrative of this question. It is hoped that these may be made the subject of a future paper.

The President announced short papers in continuation of the *Photographic Jottings*, by Mr. Martin and Mr. Leake:—by the first named gentleman upon *The Effect Produced in the Actinic Power of Light by Variously Coloured Glass;* by the second *Upon a New Field Apparatus, with some Remarks about the Using thereof;* and a paper which he should have the pleasure of reading himself, upon *Photography as Allied to Science.*

Votes of thanks were passed to Mr. N. E. Fitch and the Secretary, for their gifts to the folio, after which Mr. Wheeler was duly elected.

The meeting after the next being the annual meeting, it will be chiefly occupied with the reports and other business of the Society. All members and intending members are specially requested to attend.

The meeting was then adjourned.

Erratum: Mr. Tilstone.—The name of this gentleman was made "Silstone" in a previous report.

CITY OF GLASGOW AND WEST OF SCOTLAND PHOTOGRAPHIC SOCIETY.

The monthly meeting of the above Society was held on Thursday evening, the 12th ult. A. Mactear, Esq., Vice-President, occupied the chair.

Mr. J. Spencer, jun., acted as Secretary, in the absence of Mr. John Cramb, who had gone to Syria on a photographic tour.

The minutes of the last meeting were read and approved of.

The Treasurer, Mr. Robertson, requested Mr. Stuart to inform the Society by what method he had succeeded in producing photographs on ivory.

Mr. Stuart then exhibited several uncoloured portraits taken on ivory, of a very satisfactory character. His method of manipulating is as follows:—An ivory slab is well polished with finely-ground pumicestone, so as to be entirely free from scratches. After which it is soaked in a hot solution of gelatine, ten grains to the ounce of water. When dry, the slab is floated on a solution of chloride of ammonium, four grains to the ounce of water, to which one and a-half grains of gelatine is added. The surface is then dried before a fire, but so as to prevent the salting solution soaking too much into the ivory. It is then sensitised, by floating or brushing, with a sixty-grain bath of ammonio-nitrate of silver, and quickly dried. On the surface thus prepared print from a negative, tone and fix in the usual way. About an hour is required for fixing the picture. The surface is then to be well washed with hot water, and placed afterwards for four or five hours under a stream of running water. Mr. Stuart observed that he had consulted several artists as to the surface obtained, and he was able to say it was quite suited for colouring on.

Mr. Macnab stated that he had also obtained satisfactory pictures on ivory by a process similar to Mr. Stuart's.

Apparatus of novel construction was exhibited, including the first set of Daguerreotype apparatus which had been used in Glasgow.

Mr. Mactear exhibited some fine pictures which had been taken in a portable tent of his own construction, and which, being placed on a child's perambulator, was very easily moved from place to place.

Mr. Robertson described the working of a dark cell, whereby eight portraits may be done on one glass. An ordinary dark cell is fitted with a plate-holder, which is circular. A piece of wood is inserted between the *slide* and the plate-holder, having a space cut like the letter V, or more correctly the eighth of a circle. When the plate is exposed only an eighth part is affected, and the cap of the lens is replaced, and the circular holder is moved round another eighth, and so on till the whole has been exposed. He (Mr. Robertson) had been induced to make such a cell from having seen a picture that had been sent home from America; and, though ignorant of the mode adopted there, had found this method quite successful.

Mr. Macfarlane exhibited a stereoscopic camera, suitable also for views, and for producing six portraits, on a half plate glass, at one sitting, which was greatly admired.

The names of five new members were proposed by Mr. Stuart, to be balloted for at the next meeting, to be held on Thursday next, the 3rd instant, which will be the last of the session. It is expected to be an interesting one, papers on important subjects having been promised.

The meeting separated, after passing a vote of thanks to those gentlemen who had contributed papers and exhibited apparatus.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

The monthly meeting of this Society was held on Tuesday evening last, the 24th ult. Mr. Haines, one of the Vice-Presidents, occupied the chair.

The usual paper was one *On the Fothergill Process*, and was read by Mr. Alfred Keene, of Leamington. [See page 129.]

The specimens referred to in Mr. Keene's paper were many of them very fine, and afforded the Society much pleasure.

On the motion of Mr. Brown, seconded by Mr. Morris, a vote of thanks was passed to Mr. Keene for his kindness in furnishing the paper; and his friend, Mr. Robinson, of Leamington (the well-known "composition" photographer), being present, promised to contribute something from his experience and skill at a future meeting of the Society.

Exhibitions.

LIVERPOOL SOCIETY OF FINE ARTS.

EXHIBITION OF PAINTINGS, ENGRAVINGS, AND PHOTOGRAPHS, AT THE QUEEN'S HALL, LIVERPOOL.

For the first time, we believe, paintings and photographs are here exhibited together, the council of the Society of Fine Arts having devoted a compartment of its rooms to photographs. This department of the exhibition is purely photographic, coloured and touched pictures having been declared inadmissible, as well as copies of pictures. With the first resolution we cordially agree; but at the Manchester exhibition copies of paintings formed one of the most interesting portions, and it is, in our opinion, a legitimate application of science to art.

The specimens exhibited number about 250 or 300, but as they are not numbered or catalogued we are sometimes unable to ascertain either the subject or name of the artist. Altogether it is a very satisfactory exposition of the present state of the art in this country. The printing of nearly all the pictures shows a marked improvement, and their circulation may tend to disabuse the public mind as to the instability of photographs.

The collodion process, wet and dry, with its various modifications, is well represented—indeed almost to the exclusion of all others; for we believe Mr. Helsby's daguerreotypes and Mr. Duckworth's calotype and waxed-paper pictures are the only exceptions.

Rejlander's and Robinson's pictures attract much attention, being almost the only representatives of artistic photography in the collection.

Mr. Rejlander has sent three new subjects, prepared expressly for this exhibition, two of which are named *Do it Again!* and *Twinkle, Twinkle, Little Star!* The expression of innocent child-like glee in the one, and of calm placid wonderment in the other, are rendered in a manner which we had thought almost beyond the power of photography. We can only compare them to the beautiful pictures by Sant, the pre-eminent painter of children. We do not remember to have seen anything more calculated to impress upon us the capabilities of photography in the hands of a real artist than these two pictures.—*Shell your Coat, Sir?* is a piece of broad humour levelled at the Volunteer movement.—The exhibition of pictures such as the above is calculated to raise both photography and photographers; and the public generally, and photographers in particular, owe a deep debt of gratitude to Mr. Rejlander for his labours in this direction.

F. Frith's pictures of *Egypt and Palestine*, including the *Panorama of Cairo*, about ten feet long, occupy a prominent position; but as they have been so recently noticed in our pages, they will not need further comment.

Mr. Mudd has sent his prize picture, *Coniston Falls*, and we think three others, but they are not numbered or named.

R. Fenton exhibits a few choice specimens. His *Mill at Hurst Green*, and *Salmon Leap on the Ribble*, are two of the most exquisite pictures we have seen. His *Interiors of the Refectory and Sodality Chapel, Stoneyhurst*, are also remarkably fine as specimens of manipulation.

A series of *Views of Furness Abbey*, by William Keith, are very good, clean, sharp, and well defined, although some have a slight tendency to hardness. We have hitherto only known Mr. Keith as a positive operator, but his pictures show that he need not confine himself to that branch of the art. The *Arch in the Cloisters* we consider the best of his productions.

F. Bedford exhibits a series of *Views of Chester and Wales*, fully equal to his former works. It is interesting to notice the individuality which attaches itself even to the works of different photographers, as well marked as the touch and style of an artist. Bedford's *Miner's Bridge* is a striking contrast to Fenton's.

The pictures by J. H. Morgan, of Bristol, are already well known. The best exhibited here are *The Salmon Trap, The Water Mill*, and *The Well on the Beach.*

Mr. Duckworth has contributed nine waxed-paper and calotype pictures of temples and scenery in India, and Mr. W. G. Helsby

above fifty large daguerreotypes illustrative of the scenery, architecture, and ethnology of Tahiti, Copiapo, Chili, and Bolivia.

The fair sex is not entirely unrepresented. Four *Views of Conway and Carnarvon*, by a Liverpool lady, are quite up to the mark. They are by the Fothergill process, and are very finely printed.

Mr. Rosling has sent two frames, which have already been noticed.

The portraits exhibited are below the average of what we have been accustomed to see in London and elsewhere.

Coming so close upon the London exhibition we cannot expect much novelty; but for a provincial exhibition, or rather part of an exhibition, it will well repay a brief inspection.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

Turn once more to your model and examine with care the high lights of her charming face. Are they warm or cold? Now, nearly all, if not all, teachers will tell us they are warm, therefore you must receive my statement with all due caution, when I tell you that, on the contrary, they are cool, if not cold.* I put this assertion forward with some little hesitation (although I have reached this un-orthodox conclusion through a long and studious observance of nature), because I am opposed therein by high authority. Still, flesh certainly partakes of the nature of polished surfaces, the high lights of which are admitted to be cold. Without dwelling upon the point, however, I will merely recommend you to seek the truth where that quality ever exists, although there it is not often sought for, viz., in nature.

Having devoted so much study to the model herself, you probably turn to your work with a feeling of despair, hardly daring to hope that with mere pigments and paper you can approximate, however remotely, the exquisite delicacy of the lady's complexion; and as your eye recognises the infinite variety of tones, tints, and shades of colour which compose the shadows and half-shadows, demi-tints, greys, purples, and violets, you perhaps wish you had not undertaken so difficult a task. Now, I hope you have these feelings of despondency (unpleasant though they may be);—they are glorious signs, harbingers of bright hopes, and heralds of the highest order of success. But, if you have them not, why then you will be more comfortable in your mind, and that is a blessing too—is it not? In the first place, you will think with me that photographic colouring is really artistic, and demands genuine study and perseverance. In the second place, you will think, with the author of *A Guide to Painting Photographic Portraits*, that "the process of colouring photographs is by no means so difficult a matter as you might at first have apprehended. There are certainly some obstacles to be encountered, but they will soon be overcome," &c. As a rule, however, early beginners are much inclined to think it is remarkably easy (and discover their mistake afterwards) rather than the reverse, and I therefore warn you to prepare for the difficulties you will inevitably encounter. The man who goes unarmed into a battle-field, thinking his enemy will fly at his approach, is likely to find himself speedily conquered.

THE PAINTING.

The process I am about to describe is one essentially adapted to the beginner.

With a faint wash,† composed of madder pink, slightly modified with a very small portion of Indian yellow, go over the whole of the flesh. In doing this, charge your brush with sufficient colour to complete the wash without a pause, otherwise it will be irregular, and assume the appearance of hard edges in the most undesirable places, which you will not easily get rid of. Next take a little Indian yellow and Venetian red, using but a small proportion of the former, and strengthen your flesh-wash by hatching upon it, leaving the high lights untouched. Now strengthen all the lines, such as the eyelids, division of the lips, nostril, &c., with Indian red, either pure or mixed with a little lake; or should the same be very black in the photograph, with pure vermillion, used thin. Do not forget the necessity I have already so often urged, viz., that of doing all this gradually, and with faint and repeated touches.

* I quoted in the maxims some brief directions given by Rubens to his pupils, as transmitted to us by the Chevalier Michel. "Paint your lights *white*," said that great master (see maxim), and then adds, "Finish by passing gently over *the whole* with a brush dipped in *cool grey*." Now this would certainly render the white high lights unmistakeably cool.

† Washing, hatching, and the other technicalities here used, have been fully explained in the preceding chapter.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

N. S.—I should have answered this correspondent before now, but have mislaid his address.

Miss G.—Never lose the outline, for if you cannot restore form your only plan must be never to lose it. The lights are not in the right places for a similar reason. Not much progress since your last reached me; but persevere. I would not advise upon such a point without sufficient knowledge of the photographer in question.

J. P.—The glass positives have an opaque, and consequently light background, which is darkened in the colouring; the drapery is then painted, shade for shade, and light for light, on the back of the glass, in water or oil colours, and on the front in the usual way with powder colours. I have seen excellent effects so produced, but the process demands some artistic skill and great care.

A. G. Hetherington.—Cover the window panes with silver paper, or something as thin and transparent; this will modify the strong sunlight, and enable you to paint without shifting to another room. Near the face the background should be neither as dark as the shadows nor as light as the high lights, as, in either case, one or the other would become enfeebled, and the head consequently lose roundness and vigour.

Chromo—Ann Page—A Grateful Pupil.—The first of these correspondents, taking up the idea of the second, having stated that he is not in a position to pay for private lessons, says, "What do you think of announcing that a class would be formed upon certain terms when a sufficient number of names were obtained?" I am thinking over this hint, and if I receive any further correspondence thereon, an advertisement shall be inserted in this Journal, stating terms, &c.

A Lady Amateur.—You evidently use your colours too liquid. The hatching is hardly bold enough, and so produces a scratchy, poor effect: the touches should be broader to secure that "mellowness and softness" so characteristic of a good water-colour picture. Keep your colours pure and bright, as, although you may always tone them down afterwards, you can never restore their lost brilliancy. Soft square pointed brushes are best for body-colours, as they do not stab and drag up the surface as finely-pointed pencils would.

A Photographer.—The process is a secret in the possession of its inventor, Mr. H. L. Keens, of Maria Villa, Culford Road, Kingsland, by whom the pictures you have seen were coloured. They are not peculiar to the establishment you name, inasmuch as Mr. Keens occasionally executes work for my own and many others. You see, therefore, why I cannot comply with your request. Many colourists work in body colour with water, and give them an appearance of oil by varnishing with Chenie varnish: *a few* describe them as oil. A friend of mine endeavoured to clean one of these so-called *oil* pictures with water and removed all the colour. I think they are most permanent in oil. The silica colours are manufactured by Miller, of Long Acre. I have not tried them.

Novice.—Any of the transparent blues, lakes, and browns will, when mixed, form an excellent transparent black. The sensation produced by the harmonious arrangement of colours must always be dependent upon the healthy or morbid state of the organs through which such impressions are conveyed; but the rules upon which harmony are based (imperfect as they may be) have none the less value for that fact. You must not forget that there are various descriptions of harmony—some dependent upon the abstract quality of colour, others belonging to the arrangement of colour in connection with *chiar'scuro*. Nor is this all; for unless such harmony also accords with the subject, the mind immediately detects discord. I have seen glaringly discordant colours rendered almost harmonious by the skilful treatment of light and shade, and harmony of colour and *chiar'scuro* positively offensive because at variance with the subject. Chevreul's work is, I believe, the only book published that clearly demonstrates the principles of colouring. A great authority said, "that by dint of hard and close application to painting a person may become a good draughtsman; but that the science of colouring is the gift of nature, and cannot be acquired by study." Now I do not believe the latter part of this quotation, but it would occupy too much space to tell you why.

Obituary.—Photography has sustained a loss by the death of Mr. M. Sparling, late assistant to R. Fenton, Esq., in the Crimea. He died at Liverpool, on the 20th ult., of inflammation of the liver and pelvic abscess.

Foreign Correspondence.

Paris, April 25, 1860.

The Ethics of Photography are yet unwritten. It is not yet decided whether a photographer, whom you employ to obtain a "counterfeit presentment" of your visage, is at liberty to employ the negative for his own private advantage or not. You may be poet, painter, philosopher, statesman, or what not, and desire, for family considerations, to obtain a good photographic portrait of yourself, without the remotest idea of the publication of the same—in fact, you may be averse to such publication. Well, you go to a photographer, and sit and bargain for so many impressions; but the artist keeps the negative, which many consider they have a right to do with as they think proper. Next week, perhaps, you may be astonished to find yourself (I mean your portrait) in all the shop windows, to your infinite annoyance. You proceed to the artist, and remonstrate with him. He takes it very coolly, says you are a public character, and that your portrait is public property, &c.; but you cannot convince him that he has been guilty of any impropriety, or of any breach of confidence. You wish him to withdraw your portrait from public exhibition and sale: he declines; but you think the law on your side, and resort to its aid to compel him. But you are soon convinced of the glorious uncertainty of the law, even if you had any doubts before. Most likely the jury will pronounce against you, and the photographer will go off triumphant.

An interesting case, *à propos* to this question, came before the courts lately, the result of which has created no little excitement among the members of the photographic profession. It may some-

times happen that you are yourself willing that your photographic portrait should be accessible to the public. But you may die: what if your heirs, executors, &c., object to that which you approved of? Here, indeed, is a knotty point, which was curiously unravelled lately, in the case of the late eminent poet, Adam Mickiewitz. He had authorised M. Szweyer to take his portrait, and sell it; but, since his death, his heirs have wished that the sale should be stopped, and they appealed to the courts for the necessary power to do so. It was argued that public characters do not surrender their private rights in becoming public; that the one is entirely distinct from the other: the domestic fireside is sacred to them as to others, and their appearance in the forum, in the pulpit, or on the stage, is an existence apart, and totally distinct. A man who has lived in the blaze of notoriety may yet desire to die in obscurity, and has the right to conceal his dying bed from public gaze. The portrait of a person cannot be publicly exhibited or sold without the formal consent of the said person, nor after his decease without the consent of his family. And, moreover, when a person whose portrait has been taken, has authorised its being exhibited and sold, his family can, after his decease, oppose this exhibition and sale, if it be disposed to do so. Such is the law, and the court awards it.

This may appear like pushing family rights to extreme limits, and it is not likely that the legal principle established will be at all agreeable to photographers. The features of eminent men sometimes throw much light upon their character and actions. To the anthropologist an authentic portrait is worth more than the best biography ever written. To deprive the artist of the right to present to the eyes of posterity the features of those who influence the destinies of the world is a harshness which is prejudicial to society, without being a benefit to anyone. The pages of Carlyle are not more eloquent or informing to the thoughtful eye than the portrait of Cromwell that prefaces his volume. From the robust, square, and massive frame, thick lips, large forehead, arched brows, and eagle-glance, the lion's head and mane, of another of that writer's idols — Mirabeau — we can well divine the passions and eloquence of one who swallowed all formulæ. A good photograph of our Shakespeare would be worth more to the world than all the gold products of California. The lineaments of a great man are as much public property as his deeds. His face is as a book wherein we may read his true character. J. P.

New Books.

Instantaneous Photography, Mathematical and Popular, including Practical Instructions on the Manipulation of the Pistolgraph.
By Thomas Skaife.
(London: J. Hogarth, 5, Haymarket.)

There are but very few practised photographers who do not appreciate the advantage of a very short exposure in the camera; hence we may safely predict that the little pamphlet before us will be pretty extensively read even by those who do not propose to themselves to put in practice the precepts given, for there is something of interest attachable to the idea of *instantaneous* photography, even by non-photographers.

We presume that there are but few persons who will be disposed to question the right of a parent to name his own child; but whether the world will always adopt a designation that may be conferred by the said parent, without any regard to convenience or propriety, is quite another question. We are induced to make these remarks in consequence of the very barbarous word coined by Mr. Skaife as a name for his ingenious little *camerette*, but which he calls a *pistolgraph;* and we cannot forbear recording a protest against such a hideous and unscientific compound, and a still stronger one as regards the word *pistolgram*, which Mr. Skaife applies to the small photographs produced by aid of his instrument, and which appears to us to reach the culminating point of cacophonous photographic slang, surpassing even the original corruption, *stereogram*, and without the excuse that can be urged in defence of such expressions as — old hypo' — *et hoc genus omne.*

If the instrument had been as bad as its name, we should not have troubled ourselves with any notice of it at all; but the very reverse is, in fact, the case: the apparatus is very ingenious, and its productions truly charming.

The lens employed is very similar in construction to the ordinary portrait combination, but having a much shorter focus, and is of about one inch in diameter. To the front of the lens is attached a pair of Skaife's patent shutters, which open outwards, and which, by an extremely ingenious contrivance, are made to open and close again by merely touching a small trigger, so that the exposure (which can be regulated to any desired fraction of a second of time) may take place at the exact moment selected by the operator.

These shutters have already been described in our volume for 1858—it is, therefore, needless to repeat the description; but, as an instance of the excessive rapidity with which they can, if desired, be made to open and shut, we may state that we have seen a small pair, such as are used for the instrument we are now describing, which absolutely were made to go through the operation without the eye being able to detect any movement, unless the shutters were held between it and the light, when the flash of light became perceptible. For all the details of manipulation we must refer our readers to the pamphlet itself; but of its productions we have a word or two yet to say.

We have before us a scene on the river Thames, taken on glass (of about a square inch, or rather less, in dimensions), and embracing the "reach" of the river visible from Greenwich. On the right is a landing place, with several wherries and other small craft afloat; on the left the foreground is occupied by a fishing smack at anchor; the centre is filled by one of the Diamond funnel steam packets approaching the pier, on the paddle-box of which the master is seen directing the steersman, who is also visible at the stern of the vessel, while the deck is occupied by an assemblage of passengers. In the distance are numerous vessels, and a house or two of the town of Greenwich; and each rope and spar of the vessels, each ripple on the water, is as sharp and defined as can be desired.

We have also a likeness of Sir David Brewster, mounted as what Mr. Skaife designates a chromo-crystal, a method applicable for mounting likenesses for bracelets, brooches, &c. It consists of a small glass positive, attached, by means of a transparent cement, to a piece of dark-coloured glass of any desired hue, — the impression being thus protected on both sides by glass from injury. By this arrangement a whole gallery of family portraits can be worn as a pair of bracelets.

In conclusion, we may cite, as an example of the definition attainable by Mr. Skaife's instrument, that we have a copy of the entire front page of *The Times* newspaper for 15th June, 1859, reduced in dimensions to about half an inch by three-eighths of an inch, and in which the whole of the advertisements are readable by aid of a powerful lens.

The Photographic Teacher; or What to do in Photography, and How to do it.
By G. Wharton Simpson. Sixth Edition.
(London: H. Squire & Co., King William Street, London Bridge.)

This is one of the initiatory handbooks that we remember to have noticed favourably on a previous occasion, so that it is needless to recapitulate its advantageous points. Though we do not pretend to endorse all the recommendations therein set forth, we believe that most of them are *approved* by some authorities, and at any rate can safely affirm that the trifling cost of the work will be well incurred by beginners in the art of photography. The manipulatory details of the alabastrine process will be found in this little manual, as also a chapter on colouring the same. There is an appendix to the former editions, containing short accounts of various convenient operations, &c., such as how to transfer collodion from glass to leather, how to take positives on talc or mica, so as to be readily cut for mounting in brooches, &c., how to form vignettes, and sundry other scraps of information.

Correspondence.

NO FOCUSSING.

To the Editor.

Sir, — Noticing the discussion at the Photographic Society on the panoramic lens, I am induced to send you the following extract from the letter of a brother photographer:—"At Abbotsford a queer thing happened to me. It was getting late, and I wished to take one view of it. Being in a hurry I focussed hastily. The distant mountains are *beautifully sharp*, but the house is all out of focus. I think the house could not have been less than sixty yards off. A pretty good fact this against a no-focussing theory and lens."

Any comment is superfluous.—I am, yours, &c. X.

London, April 24, 1860.

CHLORIDE OF SILVER.

To the Editor.

Sir,—1. A print taken from the pressure-frame allowed to remain in cold water, after a time the water becomes cloudy: what is the *silver* in solution?

2. On adding a few drops of strong liquor ammoniæ it *instantly disappeared*, and the water became *perfectly clear:* what changes took place?

An answer would much oblige. Yours, &c.

AN OLD SUBSCRIBER.

[1. The cloudy appearance is attributable to the formation of *chloride of silver*.

2. That body being soluble in liquor ammoniæ accounts for the clearing of the liquid on your adding that reagent.—Ed.]

"QUANTUM EST IN REBUS INANE!"

To the Editor.

Sir,—Will you kindly permit me to ask Mr. Hart who authorised him to take up the duties of Inspector-General of His Majesty King Public's Photographic Establishments? why he assumes that they all exist in "the city?" and who informed him that every photographer closed his establishment when his printer or operator had taken a half-holiday?

As the proprietor of a city photographic gallery who cannot, in justice, be accused of being indifferent to the advancement, comfort, or health of those in my employment, I must step forward in censure of such unwarrantable conclusions as this writer draws from his comically imperfect observation. His description of traversing the city instead of the west end; his melo-dramatic exclamation of, "when, what did I behold?" and his ingenious plan of introducing an indirect puff in favour of the "noted firm," were as amusing as his sage assertion that "in any place worth calling a photographer's there is always an operator and a printer." I derived some amusement, also, from finding that the men who, after *one* day's rest, would return to their work with "a half sluggish air," would, according to his statement, return with great "freshness and energy" if they only had a day — *and a half.*

With all his apparent love of art, it is strange that Mr. Hart should overlook the fact that one of the first collections of pictures in Europe—that at Kensington—is opened free after dusk. For my own part, I should suppose our operators and printers would be more inclined to recruit their health and energy in *the fresh open air* than to devote their little leisure to close or crowded picture galleries, for the sake of study, which they would pursue to very little purpose if they had not previously made themselves acquainted with such principles and rules of art as may be acquired from books read in those long winter evenings at home which the photographic operator possesses, but which so many thousands of his fellow-labourers in other professions and businesses yearn for as a priceless but quite unhoped-for boon.—I am, yours, &c.,

A CITY PHOTOGRAPHER.

MOUNTING PRINTS—GOLD TONING.

To the Editor.

Sir,—Will you kindly inform me of the proper way to mount prints? I find the gum, although I use it very thick, comes through to the surface, occasionally bringing with it the colour of the mount. I also find the mounts of ten by eight inch pictures curl up to a great extent, even after being subjected to a pressure of about half a ton, by means of a very powerful screw press: in stereos the curling is not so objectionable.

Can you suggest any cause for the alkaline chloride of gold bath in toning, by which I have hitherto been very successful, suddenly, within the last few weeks, failing altogether to give a good colour? The solution of gold (unless it can have become decomposed in any way), is the same as I have been using with success, as is also the paper, but now the colour always changes in the hypo to a dirty brown, which is not altogether removed by the application of heat in drying.

I am, yours, &c. AN AMATEUR.

[Gum water has a tendency to penetrate photographic paper, which, after the necessary washing, is very apt to have a considerable portion of the sizing removed—a condition that may be recognised by holding it up to the light while wet, when transparent patches will be evident. Any aqueous solution also tends to make the mounting board curl up—unless it too is previously damped, so that, on drying, both the print and the mount shall shrink equally. The removal of the size may be rectified by floating the print on a solution of gelatine in hot water (three or four grains to the ounce) and hanging it to dry.

For mounting—try a solution of india-rubber in naptha (procurable at the shops); apply with a stiff brush to the back of the print, scrape off the superfluous liquid with a flat-edged piece of metal or glass, the proof being placed face downwards on a plate of glass the while; then place the print on the board in the same way that you would lower paper on a sensitising solution; press, and when dry remove any cement that may have oozed out with a piece of india-rubber, which does it effectually and simply. The print cannot safely be re-adjusted after it is once lowered on to the mounting board.

Alkaline chloride of gold will not keep long after being mixed, the gold becoming reduced. This is no doubt the case with your bath. Remedy:—Mix it only in small quantities at a time, when about to use it. Read Mr. Hughes's paper in a recent number of this Journal.—Ed.]

DISORDERED NITRATE BATH.

To the Editor.

Sir,—Will you have the goodness to inform me in your next what I must do in order to get rid of acetic acid in the bath, so as to use nitric acid instead? I have generally understood that the two acids should not be employed simultaneously; yet, in some directions which I have by me, it is first said—add so many drops of acetic acid to each pint of nitrate bath, &c., and further on, minute directions are given for correcting the bath with nitric acid.—I am, yours, &c., A. Y. V.

[When once acetic acid has been added to the bath, you will find it difficult to eliminate it, and to bring the solution back to the same state as before; for if the acetic acid be neutralised with an alkali, then an *acetate* will be formed, and produce its characteristic effects. Acetic acid is a volatile substance, and therefore it might be supposed that by evaporation it would be entirely expelled. To say nothing, however, of the uncertainty introduced by applying heat to a solution containing nitrate of silver and also organic matter tending to reduce that nitrate, it is always difficult to expel the last portions of a volatile body from its solution in another liquid. At present, therefore, we are disposed to advise you to work the two acids together, if you really require the retarding effect of the nitric acid.—Ed.]

THE CENTRAL SPOT.

To the Editor.

Sir,—1. Seeing your notice of "Onward's" explanation of the cause of the "foggy spot" on negatives taken with a portrait combination, when the stop is placed between the lenses, I could not refrain saying a word or two as to the improbability of either your own or "Onward's" being the correct explanation. That the "foggy spot" is an image there cannot be any doubt, but that it is caused by reflection from the surfaces of the lenses is preposterous!

2. Neither can it arise from the shade in front, which can be shown practically by removing the shade; the "spot" is still there (?).

3. When it projects too far, the picture on the screen diminishes gradually in luminosity from the centre to the edges. In this case the spot has a tolerably well-defined outline.

4. You say, that "to form an image the diaphragm itself must be capable of readily radiating light." It does radiate light. By the diaphragm I understand the space or area within its circumference, and I maintain that we have, on the screen, a representation of this diaphragm by radiated light—probably not perfect, because not necessarily in focus, and not wholly, or perhaps not very visibly, represented, because coated with black, except the aperture which is light, and consequently represented.

5. The front lens pictures on the glass everything before it; why should the posterior lens skip, as it were, over everything in the interior, and only begin to picture the objects outside the anterior lens? There is an aperture, circular or otherwise, and if the "foggy spot" is not an image of it, where is its image? I feel persuaded that everything, whether diaphragm, aperture, or lens, placed before the posterior lens, is represented by it according to the light radiating from such object.

I am, yours, &c., C. B. GREEN.

[1. Our correspondent has a perfect right to feel dissatisfied with our explanation of the "foggy spot," as well as of that of any other expounder, and to express his objections we are willing to afford him an opportunity; but, when alluding to others than ourself, we should prefer his using some milder term than "preposterous." The editor may be "hit hard," upon the presumption of his "having no friends." 2, 3. These paragraphs directly contradict one another. 4. Not very intelligible. The *diaphragm* is the piece of metal in which the aperture is pierced, through which the rays pass, and, in the supposed case before us, is placed between the lenses of a portrait combination. If, then, the diaphragm radiates light it is improperly constructed; it should be made of a dead black, so as *not* to radiate light (perhaps the word reflect would be better understood than radiate, but is not strictly correct). 5. The proposition is too general. No lens can form an image of anything that is nearer to it than its principal focus; the diaphragm, being between the lenses, is clearly, of necessity, nearer to the posterior lens than its solar focus, hence it is impossible that any image of its aperture can be formed by the posterior lens.—Ed.]

PHOTOGRAPHER'S HALF-HOLIDAY.

To the Editor.

Sir,—I have read the letter in your last on this subject, and have taken breath after it. After a second effort I think I almost understand what the writer means, notwithstanding his odd jumble of antecedents and relatives, and utter disregard of grammatical construction. If I understand him, he wishes to receive six days' pay for the labour of five days and a-half.

But, sir, I fancy operative photographers will be much tempted to exclaim, "save me from my friends!" for if the arguments of "J. Hart" be the best that can be advanced in support of the weekly half-holiday, the case is, I fear, a bad one. Mark the first conclusion which flows from his argument. All the operator "requires is that four or five hours on a Saturday be awarded him by his employers, for the purpose of visiting those places of instruction and amusement," &c. It is not then the duty of the operator to be qualified by education and habit for the efficient discharge of the duties of his profession before accepting its emoluments, but it is the duty of his employers to bear the expense of such education. Again, mark how conclusive the next argument is: at the termination of his weekly labours the operator has an interval of forty hours for rest, but he returns to duty "on Monday morning with a half sluggish air;" extend the interval to forty-four or forty-five hours, and he is to be imbued with life, energy, and—art!

The connection between photography, or a photographer's half-holiday, and the magniloquent periods about "foreign climes," "sunny Italy," "grand ideas," &c., I fairly confess I cannot understand, nor how a "profession" can constitute a "tomb."

I remember a quaint old saying to the effect that "there is a great deal of human nature in mankind." Remembering this, I think such letters as that of "J. Hart" are calculated to retard rather than advance the half-holiday movement. Employers do not feel they have any right to be held up to the scorn and execration of such an extensive public as read The British Journal of Photography, simply because they do not, the first moment it is suggested, give to each of their operators what would be equivalent to an annual present of eight, ten, or twelve pounds sterling. The absurdly puffing mention of a single firm is equally injudicious. We have it, sir, on high authority, that "comparisons are odorous."

Let us by all means, sir, have the half-holiday, either on Saturday or any other convenient day; but let it be honestly regarded as a boon, a goodwill offering on the part of employers, and I believe there will be found operators grateful and conscientious enough to repay their employers in the extra effort and care which will result from a sound mind in a healthy body.—I am, yours, &c.

A PHOTOGRAPHER IN THE CITY.

P.S.—I have some doubt whether your correspondent is or is not a wag, enacting the Spartan Helot or "awful example," exhibiting his own deplorable need of a weekly half-day for grammatical instruction, and referring to the "pictures which few equal and none surpass" to show the extremely low *calibre* of his own art-culture.

PHOTOGRAPHIC GOSSIP.

No. I.

To the Editor.

Sir,—In a recent number of The British Journal of Photography appears an article by Mr. Forster *On Gum as a Preservative Agent*, and it has been lately re-suggested by Mr. Hardwich for that purpose. As Mr. Forster's experience is similar to mine, a short gossip on the subject may not be out of place.

He complains of "marbling" or "brain-like markings." I should like to know exactly what these are, never having met with what I designate by these terms in any other way than by careless development in allowing the developer (pyrogallic especially) to remain stationary for too long a time. I have not, however, been able perfectly to overcome certain marks resembling *watered silk*, or a series of concentric rings formed in drying. This is more especially the case when using a firm collodion, but with a rotten film the difficulty does not appear to nearly so great an extent. The blistering to which Mr. Forster alludes arises, I think, from his using his gum solution of *far too great a strength*. I have never been annoyed in this way. Mr. Hardwich in No. 1 of his "Photographic Comments"—a series of papers which I am sure will be of great benefit and interest to photographers—recommends that the gum should not be washed off, but allowed to dry on the surface of the film. By this method the chance of blistering would be increased. In my trials I have thoroughly washed, first, to remove the free nitrate of silver, and, secondly, the gum. Mr. Forster states the keeping qualities of the plates as rather limited. Let him add a portion of albumen, an acetate or citrate, &c., to the gum solution, so as to convert any remaining free nitrate of silver into an insoluble salt, and he will find less difficulty in this respect.

Mr. Keene, in a letter to a contemporary, mentions that a plate coated with albumen, and dried, collodionised and sensitised, and afterwards well washed, is nearly as sensitive as a Fothergill plate. This is almost exactly the process as practised by Mr. Barnes. I believe it to be good, and may have a word to say on the subject hereafter. The plates will not keep.*

I next turn to panoramic photography, as discussed at the last meeting of the Photographic Society. From the first it appeared very evident that the feeling of the meeting was strongly against the subject—or perhaps I might say against Mr. Sutton. Many came there who had decided on their verdict before hearing a jot of evidence. Some who spoke against it did not even know the principles on which the lens was constructed. You yourself, Sir, pointed out the fact that the apparatus was original, and not a combination of M. Martens's panoramic camera and Archer's fluid lens. I speak thus plainly because I consider Mr. Sutton did not get fair play. It was "hit him again, he's got no friends." Why was this? Evidently that gentleman has forgotten that photographers living in glass houses should never throw stones. His *energetic* remarks sometimes amuse, but often irritate. Sometimes he forgets the gentleman, and then ——! Nevertheless, all personal feelings should be ignored in so important a discussion; but this I am more than afraid was not entirely the case here. For my part I have faith in the lens. I do not expect its performances nearly to come up to what its enthusiastic inventor promises; but that it can produce good results, at all events from rural scenes, we have what I consider proof in the view looking up the path leading to St. Brelade's Bay. The lens will be a favourite with the artist, whatever it may be with the photographer; and in this opinion I am supported by my friend Mr. Wall, whose excellent articles in your columns, on artistic colouring, prove him to be no mean authority. It is usually the custom for societies to pass a vote of thanks to the authors of papers read at their meetings, but I do not remember its being done in this instance. If omitted, it was evidently unintentionally so.

The remarks made at the same meeting on burnt-in photography were very interesting. The experiments given in the paper read by the Secretary do not appear to me to have been made in the right direction, inasmuch as they are founded on one of the carbon printing processes, wherein the picture is produced by *mechanical* instead of *chemical* action. The same subject, you will remember, was previously mooted at the last meeting of the North London Photographic Association, and I am experimenting on some of the processes for printing in various metals, given by Hunt, and more recently by Burnett. What are the colours obtained from different metals on their being burnt into glass, &c.? I shall be glad of information on this point.

Mr. H. P. Robinson has read a ridicul—— singular paper before the Photographic Society of Scotland, *On Printing from Several Negatives.* He says, "Art can be extracted out of almost anything." I don't doubt it. "A Hunt, inspired by a Ruskin, can make a picture from an oyster-shell." Very true, Mr. Robinson; *but he makes it look like an oyster-shell.* Would he throw up a tank in his "small back yard" to serve as a model for "the top of a mountain?" Or would he copy a small stream of water from "a print-washing apparatus," and call it "a river?" No, Mr. Robinson, it is not at all "singular that so little has been done in this branch of photography." I certainly advocate printing from several negatives, but let them be legitimately obtained.—I am, yours, &c.

MICHAEL HANNAFORD.

[Our lively friend surely cannot "live in a glass house," because he is clearly not very particular about the direction of the stones which he throws: they seem to be cast north, south, east, and west, and as we get our share, we presume our friends will not think we treat them shabbily in publishing the preceding letter. We do like fair play, and for every one to have a hearing, opponents as well as allies, and so we will not, at any rate for the present, reply; but, to prevent misapprehension, we will simply remark, that we dissent *in toto* from a considerable portion of the opinions above expressed.—Ed.]

* [Mr. Keene favoured us with a duplicate copy of the letter alluded to, but as there was nothing in it that we had not published long since, we did not think it needful to repeat the matter. Our present correspondent, however, errs in supposing that these plates will not "keep."—Ed.]

Case of Fatal Poisoning.—We regret to have to record the death of a son of Mr. J. A. Stennett, photographer, of Chester, a child not two years of age, occasioned by drinking a solution of bichloride of mercury which had been left upon the floor of the operating-room.

ANSWERS TO CORRESPONDENTS.

J. P.—We published it more than twelve months back.

Viator.—If you do not like a tent, why not try some of the dark boxes so ingeniously contrived?

Nemo me impune lacessit.—Fair criticism we never hesitate to publish, but anything spiteful we prohibit. Send us what you propose, and we will consider of it.

T. B.—To clean glasses that have the collodion dried on them, we find a little old spoiled collodion one of the simplest agents to employ for the purpose.

Caleb I'Anson.—You will find that a double combination lens is a nuisance for field work—particularly if you require pictures ten by eight inches in dimensions.

Margaret.—Print on albumenised paper, and tone with gold, by the process recently published by Mr. Hughes, or by Maxwell Lyte's formula.

W. B. C.—Dr. Hill Norris's process has been patented, and we are not at present in possession of such information as would enable you to prepare plates exactly similar to those supplied by the firm.

R. T. Dick.—The manufacture of positive collodion does not present the same difficulties as that of negative collodion, and you will find no difficulty in obtaining it of the best quality. The maker you speak of, for lenses, has been successful in some of his attempts, as we can testify.

I. W.—Perhaps you will succeed better if you warm your toning-bath by placing the vessel in a dish of hot water for a few minutes. The temperature will only require to be raised to sixty-four or sixty-six degrees.

Inquirer.—We could not in fairness to our subscribers occupy space with such an article as you desire, which, though interesting enough to those engaged thereon, is certainly not in any way connected with photography that we can perceive.

Transit.—We have never examined the varnish to which you allude, but should think it is probably composed of mastic dissolved in benzole. It is not generally advisable for photographers to make their own varnish, though they should know *how* to do it. Gum *benzoin* may possibly be suitable for your purpose, or gum dammar.

A Manchester Amateur.—We are not aware that Mr. Mudd has any peculiar kind of aceto-nitrate of silver bath, but would not your simplest plan be to call personally upon him? Almost any collodion will do for the process named; in preference, probably one made after the formula of Mr. Hardwich, recently published in our columns.

J. Cunningham.—A dry plate by Dr. Norris's process will do exceedingly well. Expose under a negative in the printing frame by just *showing* it to the light for an instant, and develop with pyrogallic and citric acids, of course adding a few drops of solution of nitrate of silver. Citric acid does not bring out the shadows better, but produces a more agreeable tone than acetic acid.

John Reynolds.—The dimensions of your moveable screen must depend chiefly upon your own convenience. Seven feet high by five in width for the back, would be a minimum size. The sides may be seven feet by three feet, and the top three feet by the width of the back. If you can find place for stowage, you will find eight or nine feet wide for the back preferable, as it will then be suitable for groups as well as single figures.

An Amateur.—Perhaps it will be hardly safe at present to rely upon the papers you name, which were given more in the way of experiment than of complete research. The mucilage of linseed has been employed successfully in the dry processes, and, although we have not ourselves used it, we are of opinion that it promises well. With reference to the methods of washing Fothergill plates, why not try them both, and ascertain for yourself which is most suitable for the collodion which you employ?

Beginner.—You must not expect to obtain such rapid results in a glass room as when working in the open air, for all ordinary glass, from its colour, &c., impedes the light to a greater or less extent. 1. If you use the room for portraiture only, you need not alter the east side at all, and certainly not the door. As one side of the sitter should be shaded, the light reflected from the *pale*-blue east wall would afford sufficient illumination on that side. 2. It would be an advantage to glaze the entire *west* gable, and to add two more glass panels on the same side. 3. Do away with the gable *b*, and make your glass roof slope from the present wood-work of gable *a* to the top of your dark room, and put a lead flat over the dark closet; or remove the dark room, as you propose, and continue the glass slope to the extreme north end of your room. Arrange two roller blinds to pull up from the bottom of slope, one blind for each half of the roof.

A Little One.—You are quite right. We are always ready to afford our best advice to correspondents, and are gratified that you have received useful information. You cannot make a portrait combination and a view lens work together for dissolving views; neither will you find a half-plate double combination give you so large a picture on the screen from the same negative as a quarter-plate one. You must not quarrel with the "great guns" for abstaining from entering more into elementary principles when reading papers at the societies: their audiences are too well informed on the subjects to allow such a course to be desirable or permissible, and the papers are published just as delivered. We endeavour to supply the vacancies to our uninstructed readers when we are apprised of what they consist. Send a stamped directed envelope and we will endeavour to relieve you of the difficulty not answered here.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 118, Vol. VII.—MAY 15, 1860.

At the last meeting of the North London Photographic Association, a paper of no small interest and importance was read by Mr. George Dawson, *On the Reaction of Chloride of Silver upon the Hyposulphite of Soda*, which we laid before our readers in our last issue, and upon which we have a few remarks to offer. To meet the requirements of our numerous subscribers and agents, both in this country and on the continent, we are compelled to "go to press" at least two days before the day of publication, in order that this Journal may be included with others in the provincial and continental packages; we were in consequence unable to correct the paper under consideration after it was "in type," and in the manuscript the fact of the chemical substances being expressed symbolically escaped our attention: we therefore fear that some of our readers may be somewhat puzzled to comprehend the completeness of the demonstration laid before them by the author of the article. Under these circumstances we propose to recapitulate briefly the conclusive experiments of Mr. Dawson, by which the probable source of the error into which the eminent French chemists, MM. Davanne and Girard, were led, was discovered. It is not a little surprising, however, that these gentlemen, whose elaborate investigations relative to the cause of the fading of positive proofs upon paper have been constantly referred to in these pages, should—in the instance which gave rise to the extraordinary announcement made by them to the effect that "one quart of a new solution of hyposulphite of soda, of the strength of ten per cent., is requisite to fix properly and safely only one sheet and a-half of paper of the dimensions of 22½ inches by 17½ inches"—have entirely omitted to act in the same cautious manner that characterised most of their other operations.

It will probably be in the recollection of many of our readers that several years back a committee of English photographers was appointed by the Photographic Society to investigate the same subject, upon which committee we had the honour of serving; we are consequently well informed as to what results really were arrived at upon that occasion.

MM. Davanne and Girard, in commencing their operations, did not content themselves with taking up the matter where it was left by their English predecessors, but began *de novo;* and very properly so, for there is always a satisfaction in conducting an important inquiry by commencing at the very foundation, if only to verify what has been already ascertained. During the publication of several of the earlier portions of their researches, while giving full credit for the systematic manner in which they had been conducted, we felt called upon to record a protest against the manner in which many of the ascertained facts were put forward as new discoveries, totally ignoring the circumstance that they had been previously published in this country. It makes but little difference if it be contended that these gentlemen were unaware of what had been done in the direction in which their labours were to be exerted: they could not have been ignorant that *something* had been done; and it is a recognised principle among scientific men of all countries that in such cases they are bound to ascertain what that something is, in order to avoid the appearance of attempting to appropriate the fruits of previous researches as their own. We wish it, however, to be understood, that we do not for a moment intend to charge these gentlemen with any deliberate injustice, but we cannot acquit them of at least a disregard of the ordinary precautions usually adopted in such cases.—To return, however, to the immediate object of our consideration.

Mr. Dawson, as a preliminary experiment, ascertained that the solvent power of hyposulphite of soda for chloride of silver is not—at least in any important degree—dependent upon the actual strength of the solution; but that a given quantity of the former will act upon a definite quantity of the latter, whether the quantity of water employed be much or little.

In order to make the experiments assimilate pretty closely to the ordinary conditions under which the photographer has to operate, the hyposulphite of soda and nitrate of silver were selected of good but not absolutely pure quality; the solvent of the former being ordinary spring water, while the latter was converted into chloride of silver by precipitating it with chloride of sodium (common salt). The chloride of silver was washed, dried, and subsequently added to the hyposulphite of soda in *small quantities* at a time.

Having prepared a solution of hyposulphite of soda, of the strength of ten per cent., and divided it into several portions, to the first portion chloride of silver equal in weight to one-third that of the crystals of hyposulphite of soda contained in it was added gradually; a part of this solution exposed to the air for three weeks remained clear, and without a precipitate of any kind being formed therein. This is at least a very strong fact in direct opposition to the statement of MM. Davanne and Girard, "that hyposulphite of soda becomes saturated with the double salt when thirty-six grains of the chloride of silver are added to twenty-five of new hyposulphite."

Again: Chloride of silver was added to another portion of the ten per cent. solution till a white crystalline precipitate fell abundantly, which deposit, on exposure to a heat of 180° Fahr., quickly resolved itself into sulphide of silver. The supernatant liquor, standing in a warm position exposed to the air, decomposed into sulphide of silver and sulphuric acid; but another portion of the same liquid was kept at a pretty even temperature below 60°, *for more than a fortnight, without manifesting any signs of decomposition.*

Now, let us note carefully what follows. Mr. Dawson states:—"I saturated a ten per cent. solution of hypo. with chloride of silver, and continued adding the latter till hyposulphite of silver ceased to fall.' Part of the liquor was boiled in a test tube without the expected deposit of sulphide of silver. It then occurred to me that, if this body were absent, it (the liquor) might contain chloride of sodium only; and this surmise seems to be borne out by the few tests I have as yet had time to apply." What tests were applied will be found recorded at page 127: so conclusive however were they, that the liquid

itself was employed as a salting solution for positive paper, upon which, after sensitising in the ordinary way, prints were taken perfectly clean, and presenting the ordinary appearance of well-executed untoned photographs; and two of these proofs are still in our possession. Now, had the smallest quantity of hyposulphite of soda remained in the solution undecomposed, it could not have failed to render its presence perceptible by producing discoloration of the paper.

It is clear that the error committed by MM. Davanne and Girard was in at once adding an excessive quantity of chloride of silver and yet not enough to effect the complete double decomposition. We have little doubt that they will immediately rectify the mistake into which a very large number of photographers will be liable to be misled by the authority of names so renowned as theirs—unless, indeed, they still consider it needless to ascertain what their English *collaborateurs* are doing; in which case perhaps a few months may elapse before we hear anything more of the matter, when, judging from former experience, we may expect that by some happy coincidence, finding that their assertions have been totally misunderstood, they will limit their former statements to so and so, and detail results subsequently arrived at in consequence of pushing their former experiments to an extreme, when the surprising effect of total decomposition of the original salt (hyposulphite of soda) will have been discovered to have taken place, of course simply because they will not be at the trouble of reading the English Journals.

We cannot conclude without an expression of thanks to Mr. Dawson for so clearly proving to our readers that they need be under no apprehension about fixing their proofs in the manner recently employed by all careful photographers.

It will be remembered that we published in our number for March 15 an article on *Perspective and Distortion*—the principles then advocated being mathematically correct and conclusive; but as some of our artistic and non-mathematical readers seem to fancy that a departure from the principles laid down can be allowed *without deterioration of the result*, we publish, by permission of the writer of that article, a very satisfactory demonstration, contained in a letter sent to a friend in reply to certain objections that were brought forward in defence of a departure from strict mathematical accuracy being admissible in art. The question, however, was not one of practice, but of fact, and was intended not to deter an artist from adopting it when serving his purpose, but that he should do so with a full knowledge that it involves a departure from principles by which he is usually governed. It is a subject of much interest, and we strongly recommend our readers to re-peruse the original article before or after reading the letter in the present number.

ON THE VALUE OF COLLODION AS A PHOTOGRAPHIC AGENT.

By T. F. Hardwich.

[Read at a Meeting of the London Photographic Society, 2nd May, 1860.]

We are met together this evening for the purpose of discussing the merits of a formula for negative collodion which a Committee of your Society have reported on. It will be still perhaps in your recollection that the original suggestion for the appointment of such a Committee emanated from me, and therefore I think that I am in order in desiring to open this meeting with a few introductory remarks. There are members of our own Society, and also of other Societies, who have expressed themselves as dissatisfied with the course which we have pursued, but I think that it will be easy to justify that course on the ground of necessity. The subject was not only one of great importance, but was much in need of further elucidation. Let me take these points in order.

1. The subject of collodion was one of fundamental importance to photographers. Some doubted this at first, and conjectured that in a very short time a material would be found as superior to collodion as collodion is to paper. Several years, however, have elapsed, and nothing of the kind has been discovered. Further than this, we may affirm that the more complete our knowledge becomes, the greater the difficulties appear of superseding collodion by a vehicle more adapted to fulfil the requirements of the art; for the photo-chemical properties of iodide of silver are so much affected by the exact condition in which its separate particles are precipitated, and likewise by affinities exerted towards it by other bodies, that the list of substances available as supports for that iodide is considerably reduced. Before we can select any film, it must be decided that it has certain facilities for penetration by liquids, and that the movement of the particles of iodide will not be interfered with by reactions other than neutral, such as many bodies, organic and inorganic, are known to possess. The question arises, then, whether collodion is not *the* particular substance which photographers require; if so, we cannot be at too much pains in bringing it to perfection. I have heard it said that in the chemical laboratory we should be constantly at a stand-still without a fluid metal, and that, *therefore*, we have fluid metal, viz., mercury. So in photography, since we require a support for the sensitive iodide of silver, we have a substance which is calculated to answer as a support, and that substance I believe to be collodion. If the members agree with me, they will see that the appointment of a committee to inquire into the best mode of manufacturing collodion was a proper step for the Society to take.

But 2, the question of collodion is not only important, but difficult, and to a far greater extent than at first appears. This assertion has also been doubted, but nevertheless it admits of the most satisfactory proof. Those only who have manufactured collodion in large quantities, and have continued the manufacture for a long time, are fully aware of the strange anomalies which may arise. Just when they have begun to esteem their process perfect, a new difficulty starts up; and if this be disposed of, it is by-and-by succeeded by another. In the early days of collodion photography a little manual was published by Mr. Hennah, of Brighton, which rapidly passed through four editions, and was much prized by amateur practitioners of the art. In one of these editions—I think the third—we find the author apparently satisfied with the collodion process as it then stood, and pronouncing it nearly perfect; but in the succeeding editions he is compelled to put in a foot note qualifying his previous statement, and speaking of the art as, after all, but in a transition state. "The great impediment," he says, "is the absence of a collodion of uniform character. A remarkable and almost unaccountable difference is commonly observed in the degree of sensitiveness to light of different samples of collodion, independently of the iodising solution used; and it is believed that more remains to be done in the preparation of a good collodion than in any other branch of the process; for there is no doubt that most of the superiority of this over other methods is due to the little understood properties of the collodion itself. All who have the time are earnestly recommended to give their attention to the perfecting of collodion, as the most likely means of rendering this beautiful art not only more popular, but also of extending the range of its usefulness far beyond anything it has yet reached."

I have quoted the above remarks as according with my own views, and because their author is known in this Society as a good and candid observer. If it be objected that the book to which I refer was written five years ago, I would say that, as far as any information on collodion in the possession of the Society is concerned, it might have been written six months ago; for although individual makers of collodion have improved its quality, their improvements will not be found in the pages of the Society's Journal; and this consideration brings me to my third and last point, viz., the insufficiency of our published information when this committee was appointed.

In making the assertion that the Journal of the Society contained no complete information on the manufacture of photographic collodion, I do not mean for one moment to ignore the valuable papers of Mr. Hadow and others, to whom I have on many occasions acknowledged my obligations. I simply wish to observe that there was not in the Journal such a full and minute description of the commercial manufacture of collodion as would enable an intelligent person to prepare a gallon or two gallons of that substance per diem, and to compete, as regards quality, with makers who have acquired a reputation for producing a good article. I may, however, go further than this, and affirm that any individual desiring to become a manufacturer of collodion would, by many communications contained in our Journal, be entirely led astray. It is true that, appended to these communications, we have a distinct announcement that the Society is not responsible for the correctness of the views entertained by the authors; but are we to pass our whole existence in this negative state? and will the

public, who look to us to advance the interests of the art, be satisfied by our simply collecting all that comes to hand, and putting it into the Journal with the above reservation? What they require is something for which the Society *is* responsible; and therefore, since it is well known that we have amongst us members who understand what a really good collodion ought to be, it was most natural and proper that those members should come forward and make a report? If any one thinks differently, let him state in what manner he would advise the Society to expend its funds, and to attempt the fulfilment of the expectations which have been formed of it. It has been said that to legislate on a question in which different makers have to compete and exhibit their skill is wrong; and so no doubt it would be if these makers worked by one and the same formula: but if it can be shown that a new principle is involved in the formula to be reported on, the aspect of the matter changes. It would be premature to attempt at this time to prove that the collodion now before the Society differs fundamentally from other collodions, but at a later period of the discussion this evening I shall be happy to do so. Admitting such to be the case, we are certainly in the right path; and if our efforts to give a definite formula for collodion be crowned with success, the oft-repeated inquiry, What does the Photographic Society do for the advancement of the art? will be replied to for the present.

FURTHER REMARKS ON PERSPECTIVE & DISTORTION.

By Thomas Grubb, M.R.I.A.

The enclosed is a nearly verbatim transcript of a letter which I sent two months since to a friend who had his doubts on the question of which it treats. This letter, my friend informs me, he considers as perfectly conclusive and unanswerable. Had the reasoning applied only to a certain angle of view (as 60° more or less), I should not have sent it to you for publication; but it will be seen that the reasoning applies *irrespective of the angle included;* and my chief object in publishing the letter is, that it may act as an antidote to the error promulgated in the incongruous assertion that those principles of delineation which, being carried out for an angle of 60°, give no distortion, produce a hideous picture if carried out in an angular extent of 120°.

"To ——— Esq. "*Dublin*, 1st *March*, 1860.

"Dear Sir,

"It is evident from your letter that you adopt that view relative to perspective delineation on a plane surface which, judging from my experience, I should say not a few hold as correct. Such is, indeed, what may be termed the natural *surface view* of the matter; but it is also that which will neither bear the application of sound reasoning nor the test of direct experiment. Having been led, not a few years since, to examine the question independently and for my own satisfaction, I arrived at conclusions entirely opposite. In this I am quite aware of not having discovered any new fact, or anything which had not been recognised,—at least by the few, though, it may be, unrecognised by the many. I am not able to refer you to any standard work where you will find the matter adequately treated; but I shall here shortly rehearse that line of argument which not only convinced myself, but which has enabled me subsequently, and at sundry times, to convince others of that which can alone stand the test of inquiry.

"Your ideas may be shortly thus defined, viz., that a correct perspective front view of a long rectilinear building, occupying a considerable angular extent of view, is not correctly represented on a plane by rectilinear and parallel lines, but that, on the contrary, these should be converging as they approach the extremes of the picture; and your reason for such is that ordinarily advanced, viz., that inasmuch as the lateral portions of the object are farther from the eye, and therefore subtend a less proportional angle than the more central, so they should occupy a correspondingly less space on the surface of representation.

"I am not aware whether you propose to assume that these lines shall be *curved*, in addition to being converging. That lines, straight in nature (and appearing so to the eye), should be represented on a plane projection by curved ones (where they must of necessity appear as curved lines), appears inconsistent with *ordinary* sound reasoning.

"You will, of course, bear in mind the limiting conditions:—The object, or objects, to be represented lie in one or more vertical planes parallel to each other and to the surface of delineation (or *perspective plane*); and the question at issue is — How are vertical and horizontal lines in the object to be drawn in correct perspective on the surface of representation?

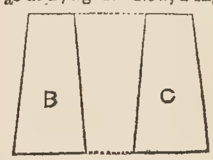
"I hold that such lines in the object are to be rendered (under the conditions) by similar lines in the drawing. The nature of the first proof I shall advance is that of the *argumentum ad absurdum*, and the case I here assume is that of a *tall* rather than of a long building.

"Suppose the object to be represented to be one of the faces or sides of a square vertical tower, having parallel and of course upright sides, the horizontal line of sight touching the bottom or base line of the tower, and the point of sight at that distance which will cause the top of the tower to subtend an angle of 30° to the horizontal line of sight, I assume an angle of 30°, not that there is any peculiarity connected with that angle, but partly because it is about the maximum which an artist expects to include in a plane projection, and partly because a lens can be so constructed as to include that angle on each side of the central (or vertical) ray, without palpable distortion.

"If, in the delineation of the proposed tower, we adopt those principles which would lead to the adoption of curved as well as converging lines in representing a long range of building, then the tower would be represented as in fig. 1; or, if you prefer to adopt straight converging lines, then the tower would be represented as at B, fig. 2. Now, I shall take

FIG. 1.

FIG. 2.



the liberty to add another tower C to fig. 2, similar to B, leaving a space between equal to the breadth of a tower.

"The force of the *argumentum ad absurdum* is now apparent. By giving the lines representing the sides of the towers the supposed necessary convergence due to the tops of the towers being farther from the point of sight than their bases, a diametrically opposite process has necessarily taken place with the space between, by virtue of which this space—*equally retreating at its top with the towers*—is made to *increase* instead of the reverse. If you attempt to project this space *converging*, as the towers, by making the latter lean, you get a step deeper into the dilemma; and should anyone imagine that a tower and a space as above are not to be drawn upon the same principles, I drop a third parallel tower between the other two, retaining the visibility of the bounding lines of contact, and presume that no one will have the hardihood to say that the resulting drawing represents a vertical triple building with vertical parting lines. It is indeed easy to observe, from mere inspection, that *none but vertical* lines will, under the conditions, represent such triple building.

"We have also a most ample mathematical proof of this, as follows:—

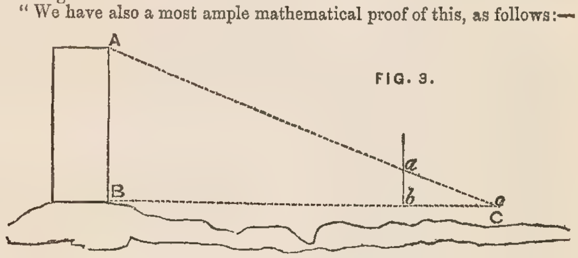


FIG. 3.

"Let A B, fig. 3, represent one such tower, C the point of sight, a b section of a transparent plane placed parallel to that side of the tower which the point of sight is opposed to, and suppose a ray proceeding from each of the four angles of the side A B of the tower to pass through the transparent plane a b, and meet at the point of sight C.

"A pair of these rays is represented by the lines A C, B C, and as the larger triangle, A C B, and the smaller, or a C b, are similar, it follows that $a\,C : b\,C :: A\,C : B\,C$; therefore, whatever reduction in *angular* measurement the top of the tower suffers at the point C, by its increased distance, as compared with the base, the same reduction in angular measurement will the corresponding part of the image bear (or suffer) from the same point C, when viewed from C on the transparent plane.

"We thus have a *full, perfect*, and *exact* equivalent in the varying distance of the plane from the point c, for the varying distance of the face or side of the tower, and therefore the vertical lines of, or on, the tower's front are to be represented on the transparent plane *by vertical lines, and by no other.*

"I shall now give you another mathematical proof, not only that these lines of representation on the plane must be vertical, but also that they must be *straight.*

"Take any straight line on the aforesaid tower's front—vertical, horizontal, or inclined, it matters not—and suppose rays to proceed from as many points of this line as you please, to the point C, without being refracted (or bent). Now the horn-book of mathematics teaches us that all these rays must lie in one and the selfsame plane, and it would be absurd to suppose that any section of that, or any other plane, can be a curve—it must be straight, and, therefore, wherever the transparent plane of representation a b cuts this plane (it may be close to the tower, or nearly touching the point C, or anywhere between) the section is a straight line, and where, as in the case before us, the surface from which such a series of rays coming from a straight line in the object emanates, and the surface of representation (or transparent plane a b) are parallel, the line in the object, and its representative line on the surface, a b, *are parallel*

lines in the same plane, and therefore must be *equally straight and perfectly parallel*.

"The foregoing proof you will, I doubt not, perceive to apply equally to horizontal (or flat) and vertical (or tall) subjects. This is easily demonstrated. Whatever is true in respect of the single tower of 30° above the line of sight, must be also true for a similar tower inverted and subtending 30° below the line of sight. The two towers thus united would form, in outline, an equivalent to one tower of 60°—one half being above, the other half below the line of sight.

"This object, revolved in its own plane, and on the line of sight as a centre, through 90°, would give an outline similar to a long range of low buildings, the line of sight being exactly central.

"To suppose that such change of position of the object can involve any alteration in the nature of its projection on the transparent plane, *a b*, is too absurd to require refutation; but, as you are a photographer, you can try the matter experimentally by rigging up a good broad plank on a centre, and observing its image in the camera in all positions. You surely will not expect to see the pheuomenon of a straight-lined figure in one position swell out into a barrelled or cigar fashion in another. In conclusion, I would remark, that although I have taken the illustrations as for 30° from the line of sight, the reasoning is equally good for 60°."

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 4.

There exists at the present time, amongst English photographers, a disposition to criticise the papers of MM. Davanne and Girard; and, although the writer of these "Comments" objects very strongly to enter upon any discussion which may become personal, he will not permit that feeling to prevent him from expressing his opinion. MM. Davanne and Girard have undertaken to examine the whole subject of positive printing, and to explain it in a scientific and rational manner. Their papers bear no appearance of being mere compilations, hastily thrown together, and asking for indulgence on the part of the critic; but are evidently intended for experimental researches, carefully matured previous to publication. It is, therefore, with a feeling of disappointment that, after a careful perusal of them, we find we have little that is new to enter in our note-book, and that many statements advanced by them are directly opposed to what we believe to be the truth.

The first cause of complaint which we entertain against MM. Davanne and Girard is that they do not sufficiently inform themselves on what has already been done; consequently we are continually startled at finding observations which we distinctly remember to have seen published years ago, either stated as new, or inserted in such a manner that they might fairly be taken to be new. The English journals are perhaps less read in France than the French journals are in England, and it is well to exercise charity in these matters; still the omission has the appearance of carelessness, and, to say the least, it does not prepossess in favour of the writers. Hence, if at the present time a voice should suddenly rise, and accuse us in plain language of being prejudiced against MM. Davanne and Girard, it is doubtful whether we should be able to offer a denial: we could only say that no prejudice of ours should be allowed to interfere with a cordial recognition of any new facts which they might discover.

But a more serious drawback to the usefulness of the researches now under criticism is, that they are too dogmatic and authoritative on matters which do not admit of being settled in a summary manner. It is an easy thing to step in with chemical formulæ and to decide at once a question which has agitated the minds of photographers for years, but will the intelligent reader be convinced by such a course of proceeding? We think not. For instance, in the paper on the fixing of proofs, we find it said to the effect that the sub-chloride of silver is decomposed by the fixing agent, and leaves a residue of spongy metallic silver, which forms the image.* Now we wish to protest against such an hypothesis, and to put on record our most confident prediction that, in ten years from the present time, no well-informed chemist will entertain it. In order to be sure that the views which we now express are, in substance, the same as those brought forward in July, 1856, in a paper *On the Composition of the Image*, we have referred to that paper, and find it therein stated that the author believes the only essential elements in photographic printing to be oxide of silver and organic matter; that the oxide of silver is reduced more or less completely, and that the product remains in union with the organic matter. Nothing definite was said as to whether this product of reduction consisted of metallic silver, or of a low oxide, but the probability was thought to be in favour of the latter, inasmuch as sub-oxides are known to unite with organic substances, whereas metals have not been shown to do so. Observe, we make no allusion whatever to chloride of silver, because we believe that photographic prints are obtainable without chloride of silver, although this body is useful in giving *rapidity* to the insolation. We have on many occasions expressed our belief in the existence of an inferior chloride of silver, containing less chlorine than the white chloride; but, that a decomposition of this body by the fixing agent forms the photographic print, we are not for a moment prepared to admit. The proper view to take of the photographic print, in our opinion, is that of a sub-compound of silver attached to the animal or vegetable supporting basis by a mordant action; and the nearest resemblance we can think of at this moment is the red stain on linen, known as "an iron-mould," and caused either by an oxide or a basic salt of iron attached in a peculiar way to the fibre.

As regards the fixing of a paper print, we also prefer to dismiss from our minds all preconceived ideas as to the solubility of chloride of silver in hyposulphite of soda, and to consider that we have in this process to deal with animal matters, albumen or gelatine, coagulated by nitrate of silver; or sometimes with vegetable substances in union with nitrate of silver. Let no one suppose that the whole of the nitrate of silver will be extracted by a previous washing of the print with water, for it has lately been shown that not even salt and water will immediately decompose these organic combinations with nitrate of silver. Moreover, a fixing agent, if intended to dissolve them thoroughly, must be much stronger than theory would indicate for chloride of silver; and time must be allowed for its proper action, otherwise the print, although fixed on the surface, will exhibit yellow patches in its substance. Any one who is doubtful of this may precipitate a little albuminate of silver, and, after darkening it slightly, try to extract the excess of oxide of silver from it by means of hyposulphite. He will find that he has a far more refractory substance to deal with than simple chloride of silver.

P.S. Since the above article was written, a paper, read before the North London Association by Mr. Dawson, has been placed in our hands; and although at the present time we have not had an opportunity of repeating the experiments therein described, we are nevertheless quite prepared to believe them; for we have observed the behaviour of hyposulphite of soda with salts of silver, and have noticed how strong its affinities in that direction are.

* We are aware that MM. Davanne and Girard have of late spoken of argento-organic compounds, &c., but no mention of organic matter was made in their first communication, in the *Bulletin* of June, 1855. At that time they considered the image to consist of pure metallic silver, and it does not appear that they have ever made any acknowledgment of error in having originally entertained such an opinion.

ON THE INFLUENCE OF LIGHT & HEAT IN CHANGING THE PHYSICAL PROPERTIES OF BODIES.

By J. Kibble.

[Read at a meeting of the City of Glasgow and West of Scotland Photographic Society, Thursday, May 3rd, 1860.]

It might almost be considered, from the voluminous papers written upon the influence of light in darkening the various salts of silver when in contact with organic matter, that the subject by this time must be nearly exhausted; but, as a proof against any such supposition, we have only to remember that an ordinary lifetime is insufficient to mix a very few grains of any two substances in their various proportions; so that what is yet to do in submitting the 62 elements already recognised by chemists, which comprise the earth we inhabit, in all their different proportions, to the action of each other, and that under different degrees of temperature, of pressure, under the influence of electricity, and of the two former combined in vacuo, and numberless other arrangements, will require a period of time as difficult for the mind to conceive as the comprehension of eternity itself. This remark I make chiefly to remove the idea possessed by many that their time is too limited or their means too inadequate to enable them to enter into the field of investigation. Also, many consider their chemical knowledge too feeble to enable them to add any information to that already amassed. But I trust a very simple question will dissipate any such false impression—and that is, whence our knowledge of the darkening influence of light on the chloride of silver? Was it originally the result of investigation? Certainly not. It was the effect of a cause made palpable to the eyesight when wholly undreamed of, and which could no more be hindered from imprinting the fact on the retinæ than the sounds which I now utter from being the means of communication between us. The whole merit, after having seen the effect, consisted in analysing the mode of action of the cause, which merit without doubt belongs to the illustrious Scheele. Yet, notwithstanding the laborious researches

of subsequent philosophers, on account of the mysterious nature of the subject, there still remains much to be learned. All must admit who have practised photography that wonderful changes have resulted from apparently trifling causes, which, although not satisfactorily explainable, are nevertheless of great value. One great source of change is heat. The annoyance given by a very few degrees above the average summer temperature must be too familiar to all of you to require any enumeration at the present time; but, perhaps, although not directly connected with photography, I may be allowed to bring under your notice a few instances of the important part caloric plays in chemistry, and which in all probability exercises similar actions in many of our own processes, as yet unsuspected, which will at the same time show the necessity of precision in noting all experiments carefully, so that when a result of any consequence is attained, the same can be accurately repeated. The first substance I shall mention is one familiar to all of you—that fluid by which the yolk of egg is surrounded, albumen. In its ordinary state it is semi-transparent, nearly colourless, soluble in water in all proportions. Increase its temperature to 165 degs., and mark the change. The mobility of its particles, until acted on by some other force, is destroyed, its transparency gone, it no longer dissolves in water; it now presents a beautiful white porcelain aspect, which will dissolve with the aid of heat in hydrochloric acid, producing an exquisite purple solution, although *both* substances *previous* to solution were colourless. Gelatine, on the other hand, which is almost insoluble in cold water, by the addition of a very few degrees of caloric, loses the cohesion of its particles and enters into solution. Again, the carbonate of lime, when crystallising from cold solutions, arranges its particles in the form of Iceland spar; when from hot solutions, in the form of aragonite. Both these minerals, although composed of exactly the same amount of carbonic acid and lime, are physically quite different. Still more striking, and also from the authority of Liebig, cyanuric acid, which is crystalline, soluble in water, capable of forming salts with metallic oxides, when heated in a hermetically-sealed vessel, and a high degree of temperature applied, becomes a volatile and highly corrosive fluid, which cannot come into contact with water without *instant* decomposition, and which, if kept at the common temperature for some time, is converted into a white substance resembling porcelain, absolutely insoluble in water, *no* constituent being separated, nor any body taken up from without. Thus we see the same constituents, in *exactly* the same proportions, when made subject to a different molecular arrangement by heat, form compounds with totally different properties. Phosphorus also undergoes similar transformations. In its ordinary state it is almost colourless, dissolves in bisulphuret of carbon in all proportions. In small quantities it is exceedingly poisonous; when exposed to moist atmospheric influences, it *oxidises*, forming a deliquescent acid. If heated in a vessel from which air is excluded, and kept at a temperature ranging from 464 to 482 degrees, its former properties are destroyed, it becomes of a brownish red. A quantity that formerly would produce certain death is now inert on the animal system; it does not change in moist air, and is now insoluble in bisulphuret of carbon. A low red heat once more restores its original properties. Another very singular instance may be adduced, in the conversion of alcohol, by the influence of heat and sulphuric acid, into that most invaluable of all bodies to the photographer, ether. If the alcohol be above 90 per cent. the amount of sulphuric ether obtained is proportional to the amount of the former used. The sulphuric acid on the other hand, until weakened by the water left by the alcohol, retains its powers of conversion unimpaired. Witness the action of heat on metallic zinc. Up to 210 degrees it is brittle, from 210 to 300 degrees, the particles admit of considerable freedom of motion on one another, and can be rolled into sheets without at all impairing the cohesion. Raise the temperature a very little, its ductility is destroyed—the metal now separates with the blow of a hammer. Again, increase the heat, fluidity begins; the particles now move over each other with the greatest freedom. At a still higher heat, repulsion ensues; the particles now repel each other. If in a close vessel the metal distils, becoming solid once more on the loss of caloric. May there not exist analogous actions, although more imperceptible, and of a more delicate nature, in the arrangement of the particles in the act of reduction by actinism, or in the toning by heated solutions? Would such a result be more wonderful or inexplicable than the following:—Take two parts of sulphate of soda, one of water, dissolve by a high heat; almost fill a glass vessel with the solution, set it aside to cool where it will be free from vibration. After having covered the mouth of the vessel with a card-board to keep out dust, and when cool, say three or four hours afterwards, take a glass rod, immerse it in the solution; crystallisation immediately takes place, radiating from the rod until the whole becomes a mass of crystals. Repeat the experiment, but this time heat one end of the glass rod in the flame of a spirit lamp. Then, after it has thoroughly cooled, immerse it as before. Mark the change; no crystallisation takes place, even although freely moved about in the solution. In the first instance, the motion communicated by contact with a piece of the same material as that holding the solution, but which has *not* been heated and cooled along with it, is propagated from particle to particle, until the fluid becomes a solid. An increase of caloric seems to have destroyed some property possessed by the end of the rod that was heated; on applying the opposite end, which has *not* been heated, crystallisation again takes place. The glass rod, if kept in a closed vessel, does not regain its original properties for about 14 days; in the open air 3 or 4 days is sufficient. Here once more an immaterial agent acts a part that cannot satisfactorily be explained: at the same time, not more wonderful than bottling light, and photographing with it in the dark. If proof of the above could not be established, the assertion would be considered about as idle as the idea of the alchemists of old, that the inferior metals could be transmuted into the nobler. Nothing *material* added to or abstracted from; nevertheless, a body loses all its former properties and becomes possessed of new ones. Seeing the very remarkable part caloric plays in ordinary chemistry, is it not more than probable that its influence may be exercised to an equal extent in photographic chemistry, such as in the toning bath? That heated solutions darken the image more rapidly will, I think, be admitted; but whether it fixes or puts beyond the farther influence of light to a greater extent than solutions at the ordinary atmospheric temperature, time alone can determine. May there not exist particular points in the process, at which the *converse* of fixture takes place—at which the particles may arrange themselves in a manner ready to be acted on by a very slight disturbing force, such as the actinic rays? Have we not in the photogenic science a very striking example of opposite effects from a continuation of the action of the same cause? It is well known to all of you that a certain amount of exposure of one of the sensitive surfaces—viz., iodide of silver—to the actinic rays produces a certain effect which is again destroyed by a prolonged exposure. Indeed I attribute the great success in producing what are termed instantaneous results to accident in shutting off the exposure in the camera at *that particular* time when the intense lights, such as from clouds and water at the angle of reflection have, as it were, to a certain extent neutralised the actinic force after it had reached its maximum—the action of the high lights decreasing, whilst the feebler lights increase their force. For instance, let the subject be a highly illumined landscape, with hazy clouds overhead; allow the proper exposure for the cloud to be *one* second, for the landscape five seconds; but suppose that five seconds would completely destroy the action established by the cloud-rays, by shutting out the image say at three seconds, the action originally gained by one second will be considerably weakened. At the same time the rays from the landscape will have been increasing in force, so that you can easily imagine a point when the two states of the actinic force will be nearly balanced, and an exquisite result attained. I had in my possession at one time a positive upon paper which during a few years underwent a succession of changes until latterly the image became quite faint, and has all the metallic lustre of sensitised positive paper that has been exposed for days to bright sunshine. There was undoubtedly a re-arrangement of the particles of silver from the action of light itself, or, perhaps, in conjunction with some chemical unwashed from the paper: if the latter, it points out the necessity of thorough washing. About four years ago I varnished several paper positives with albumen in the state you get it from the egg. After being thoroughly dried I enclosed them in their frames, covering the back of them carefully to exclude dust. The whole of the delicate tints have now vanished, whilst others from the same negative—which were sensitised, printed, and fixed in the same solutions, but without the after coating of albumen—seem in no degree changed, although hanging side by side with the others. This must be due to the small quantity of phosphorus and of sulphur existing in the albumen, forming combinations of the metal, both of which are subject to re-arrangement of particles under the actinic rays. This may also account for the very small quantity of hyposulphite of soda that will render photographs destructible, if not properly dissolved out of the paper. I may here mention the apparatus I used when working with small photographs, and which thoroughly separated all the loose chemicals from the paper in a few minutes. This was effected by first steeping any number of them in a large quantity of clean water, then passing them—several at a time—

between a pair of glass rollers mounted for the purpose, the upper journals of which are acted on by stiff springs so that a considerable amount of pressure was given out, at the same time neutralising any bad effects from the inequality of the rollers. This pressure could be increased at will by turning a pinching screw over the springs; the imbibed fluid being well expressed in each passage was immediately replaced by the clean fluid, into which they fell, and so on until satisfactorily washed. I found a very few minutes of this mode superior to hours of steeping, dripping, or pressure with a sponge. Brass rollers, electroplated with silver, with a thin wash of gold on top of it, would be equally efficacious, and much more easily made correct—of course, in a system of this kind care must be taken not to use too much pressure, or elongation of the paper will take place. When on the subject of the fading of photographs, I will communicate for your investigation a theory that arose in my mind some time ago, but the accuracy of which circumstances prevented me from satisfying myself by experiment to the extent that I at one time intended. It is as follows:—The surface of sensitised paper that has been allowed to darken under the influence of the actinic rays, is considered, according to the atomic theory, to be composed of innumerable atoms of the darkened body, placed at inappreciable distances from each other—that is, every particle is surrounded by space, not filled with the body itself, and which allows room for freedom of motion under a disturbing cause; at same time, so nearly approximated that the highest optical power fails in discovering separation. Now, when chloride of silver is subjected to the ray power, a visible change takes place, doubtless effected by motion of the particles in the act of a new arrangement; also, accompanied by reduction of the chloride to metallic silver. We have only to imagine, during this change, one or more revolutions of every atom composing the external film of the chloride, which after the change may be considered as so many infinitesimal spheres, composed externally of reduced silver, internally filled with almost unchanged chloride, which has been protected from the further influence of light by the outer film. Now, in the fixing of hyposulphite of soda, you have only to conceive a partial thinning of the sphericles, which will bring them into a condition unable to resist the penetration of light under a continued exposure, which, by getting access to the inner chloride, will, by reduction, cause chloride to evolve, which, in turn, will act upon the metallic surface by which it is surrounded, and although producing the very substance (chloride of silver) that formed the image originally, will now exist under very different circumstances, and only darken to that faint violet tint so similar to faded photographs. By way of illustration, a similar action, but purely chemical, may be given:—Precipitate chloride of silver from an extremely dilute solution of the nitrate. It will fall in a very finely divided state. After washing the precipitate, pour over it a weak solution of aqua potassæ; boil it for a short time; stop the process immediately it is pretty dark; again wash; pour over it nitric acid; the darkness will disappear, the chloride appearing as before. This arises from the nitric acid dissolving the external coating of oxide of silver from the particles of the chloride, the boiling with potassæ not having been continued long enough to effect decomposition throughout the mass, and may represent a certain exposure of the chloride under actinism. Indeed the same experiment can be made with the chloride which has been exposed for a considerable time under light. I am of opinion there is a considerable field in this direction for future investigation, and of a highly-interesting nature. But knowing there is other business on hand this evening, I will trespass no further on your kind patience.

ON PHOTOGRAPHY IN ITS RELATIONS TO THE FINE ARTS.

By M. Claudet.

[Abstract of a Paper read at a Meeting of the Photographic Society of Scotland, May 8th, 1860.]

After expressing the pleasure he felt in having been admitted a member of the Society, M. Claudet said, that in Scotland the art of photography had already attained the highest state of perfection; in proof of which he referred to the annual exhibitions of the Society, in which from time to time were gathered together pictures displaying a high degree of merit. The subjects embraced in these pictures were of a very varied character, comprising mountain scenery, general views, old ruins, &c. The Scotch possess in their country rich and abundant subjects for their pictures, which could not fail to develop in them a taste for the photographic art. Every country imparted to photography a peculiar merit of its own, and for this reason Scotland was called upon to occupy a conspicuous position among the various schools of photography.

He would at that time treat of photography in its relation to the fine arts. When the present state of photography was considered, and the vast strides it had made during the last four years, it would seem that a more perfect process could scarcely be wished. The highly sensitive plates on which even such subjects as the waves of the sea could be fixed, were results which only a few years ago would appear difficult to have attained; and supposing photography to make no further progress, it was in its present state a most valuable auxiliary to the artist, as an agent in the hands of whom its application required taste and discrimination.

In taking a picture the first care was to select a fine subject, and that attained, the next point was the selection of a proper point of view from which to take it, and, lastly, the hour of the day at which the lights and shades would be most effectively rendered; for by taking the same view under different conditions of light very important changes were apparent. All those points having been attended to, the photographer should then never leave the place until he had obtained as perfect a picture as possible. He must seize his subject at precisely the right moment, otherwise, although he might obtain a perfect photograph, it would not be an artistic picture.

Photography was an art in which only genius and talent could rise to a high position. In the immense number of photographs exhibited during the past five years how small was the number meriting the designation of really fine photographic pictures! There was neither pleasure nor merit in doing that which did not cost trouble or talent.

Photography would increase the taste for the productions of art; and, reciprocally, art would increase a taste for photography. Photography was the imitator of nature—the drawing was perfect, and the perspective correct. It was the image of the objects depicted in the retina which, if transitory, still was susceptible of leaving on gifted minds an impression capable of being continually recalled by the powers of memory. Photography was to the fine arts what logarithms were to mathematics; by its means work was more easy, and was more rapidly accomplished. It was to the artist a vocabulary which guides him as the handbook of nature.

Why had photography been invented? The story was a simple one. Men of science had long ago tried to ascertain the action of light upon certain chemical agents. This was merely as a philosophical inquiry, but such inquiries being sufficient to prove that light caused changes in such substances, a desire was awakened in artists that the images of nature represented in the *camera obscura* should be fixed. Wedgwood was one of the earliest to enter this field of research; but, although he obtained photographic pictures, he was unable to fix them from the further action of light, hence they had to be kept in the dark, and could only be viewed by a feeble light. N. Niepce having found that certain bituminous substances were rendered insoluble by light, founded on it a process then well known. This process, however, was too slow to admit of its general application, and at that stage Daguerre and Talbot came into the field with their experiments. By a curious coincidence, the two discoveries of these gentlemen were made simultaneously in France and England; and, more singular still, they each presented a novel and peculiar feature, for both of them had found substances sensitive to light, but not sufficiently so to bring out a picture by an ordinary exposure to its action. They argued in this way:—If the light of the camera has not been intense enough to produce a complete impression, the sensitive surface must yet have received an action which must be capable of being completed by other chemical re-agents.—The difficulties in their way were innumerable, but both eventually succeeded in developing a latent picture: one by the action of the fumes of mercury, and the other by a solution of gallic acid. The Daguerreotype process had since that time been very much improved. He himself (M. Claudet) discovered the peculiar accelerating effect of chloride of iodine and bromine, which he had published on June 10th, 1841; and subsequently others had laboured to improve photography, chief among whom were Niepce de St. Victor and Scott Archer—the latter a most unpretending and deserving man, who died before he got the reward of his merit; but a collection for whose children was now being made, which he hoped would be liberally contributed to by all who had derived pleasure or benefit from the practice of the collodion process.

From the moment of Archer's improvements being introduced Talbot's process might be called instantaneous; and he considered that Daguerre and Talbot were justly entitled to be considered as the fathers of photography. Daguerre was a professional painter of some reputation, and was renowned for his invention of the diorama. He was in the habit of making his sketches by the aid

of a camera, and had often thought how much his labour would be lessened were it only possible to fix these pictures at once. Fox Talbot, an independent gentleman, was in the habit of taking sketches during his travels, and was induced to try to fix the camera image by means of some chemical application. Both were amply successful in their endeavours. M. Claudet thought it was only an act of justice as well as of courtesy that the name Talbotype should be continued to be applied to the pictures invented by Mr. Talbot. Since photography had been invented because fine art was in want of it, was it not ridiculous to suppose that art could be injured by it? In miniature painting it had been of the most signal advantage, as it very materially shortened the sittings. A photographer of taste, feeling, and judgment, although not a painter, might yet know how to place a model so as to give the greatest possible grace to a picture, and a painter could not fail to find among the productions of such many excellent models for study, as photographers arrange and pose many subjects daily, while the painter only arranges what he can paint. M. Claudet spoke at some length of the commercial importance of photography, showing how it had given an impetus to various branches of trade and science, more especially to glass-making for optical purposes—the construction of glass-houses—chemistry—the construction of lenses, which had been brought to a high state of perfection; and he concluded by some remarks on the application of photography to the stereoscope.

THE FOTHERGILL PROCESS.

By Alfred Keene.

[Read at the Meeting of the Birmingham Photographic Society, April 24th, 1860.]

(Concluded from page 129.)

The principle of the Fothergill process is the formation of a sensitive compound of albumen and nitrate of silver, not on the surface, but in the porous cells of the collodion, by diluting the silver solution on the surface of a sensitised collodion plate, to a point that does not coagulate the albumen afterwards applied, and subsequenly washing away all excess of the latter; and it has been received as an established fact (first, I believe, promulgated by myself, and confirmed by general experience), that sensitiveness decreases in proportion to the extent of the dilution until it reaches a point equivalent to non-sensitiveness—hence the necessity for the bath solution and albumen being brought together in certain relative proportions. This, however, has lately been denied by a correspondent, "M. N. P. S." in one of the journals, who maintained that little loss of sensitiveness was produced by even thoroughly washing under a tap previous to the application of albumen, and advocated the preparation of plates in this manner, asserting that he had practised it with much success. A statement so diametrically opposed to all former experience, and likely, as I fully believed, to cause much disappointment, necessarily led to a discussion. In order more completely to satisfy myself of the correctness of the opinion that there was the decrease in sensitiveness generally believed to be produced, I prepared something like thirty or forty plates, with the use of various quantities of water, and exposed and developed them under circumstances that would ensure a correct comparative effect. The following is a summary of the result, which fully established the opinion I had arrived at:—

The use of one drachm of water to every five and a-half superficial square inches of sensitised surface taken as the standard, 1; the use of one half more water, being one and a-half drachms, reduces sensitiveness to half; the use of six drachms reduces it to $\frac{1}{18}$; and the entire removal of all free nitrate, by washing in *pure* distilled water (to prevent the formation of a sensitive chloride of silver) subsequent immersion for an hour in a three-grain solution of iodide of potassium, and again for half-an-hour in a second three-grain solution, and well washing, required, in November, an exposure of four hours to direct light under a negative, equivalent practically to *non*-sensitiveness.

Finding, however, "M. N. P. S." still to adhere to his former statement, notwithstanding the publication of these facts, and having no reason to doubt his veracity, it became necessary to look for a solution of the enigma to some peculiarity in the mode of preparation that admitted of the thorough washing, but had not received credit for the important influence it exercised; and after some consideration, it occurred to me probable that if the plate were coated with albumen previous to the collodion (a plan, as you are aware, much adopted, both in the wet and dry processes, to make the film adhere more firmly, and save the risk of damage from imperfectly cleaned plates), there might be, by endosmosic action, *the same sensitive compound formed as in the Fothergill process*, which would, of course, admit of any amount of water being used previous to the second application of the albumen, and at once account for our varied experience.

A few experiments settled the matter. They showed that a plate, little less sensitive than an ordinary Fothergill one, could be prepared by first coating with albumen, and, when dry, with collodion, sensitising and well washing, *without* any second application of albumen. This, which at first sight promised to give a most simple dry process, has not so far proved practicable, it being necessary to use a second application of albumen, or something similar, to sufficiently get rid of free nitrate, to avoid stains. The following is the plan of preparing plates I have as yet found answer best:—Coat the plate with thin albumen, composed of—

White of egg.................................. 1 ounce.
Distilled water .... 24 ounces.
Strong liquor of ammonia......... 20 or 30 minims.

Agitate and filter, and quickly dry, by holding it near a brisk fire; then coat with collodion; sensitise in a thirty-five-grain bath; wash under a tap or in a dish with two changes of water; apply either the dilute albumen previously mentioned or the ordinary stronger one (the latter I prefer); wash as before, and drain and dry, as recommended for Fothergill prepared plates. At first, I used the strong albumen for the first coating and the weak one for the second; but with this there was a tendency to blister, which has not shown itself, so far, when the thin albumen is used first. I am disposed to consider that the sensitiveness of plates prepared in this manner is quite equal to the Fothergill process ones. Less care and skill is certainly required in their preparation, and from the sensitive compound being under the film, and free from atmospheric influence, the keeping properties may be expected to prove almost unlimited; and if the results should prove equal, and blisters absent, it is a modification likely to be much practised.

In conclusion, I have the pleasure to lay before you a few prints, kindly lent me by Mr. Ebbage, of Leamington, all from negatives prepared according to No. 1 plan, viz., the use of one drachm of water to every five and a-half superficial inches of sensitive surface; also a negative, illustrative of the keeping properties of this plan, the plate having been prepared a month prior to exposure, and kept in a temperature frequently reaching as high as from sixty-five to seventy degrees. You will perceive it shows no signs of decomposition, and had not lost anything in sensitiveness. Mr. Ebbage informs me that his average exposure with a Ross's lens for 10 by 8 inch plates is not more than three minutes.

ON THE ENLARGING OF POSITIVE PROOFS.

By M. Bertsch.

When a section of the cone of solar rays, transmitted through a non-achromatic converging lens, is projected on a screen, we remark, if the experiment is made within the principal focus, that the field is composed of a brilliant central disc, representing about a fourth of the illuminated surface, then of concentric circles of varying intensities. This appearance is due to dispersion. The central disc is the image of the pencils which traverse the axis and neighbouring parts without being sensibly refracted; while the zone that surrounds it, produced, on the contrary, by the most inflected pencils, is only a mixture of violet light with white light.

Next come, in the well-known order, zones of blue, green, yellow, orange, and red, so that the field of light is always fringed with red. If the experiment is made beyond the principal focus of the collective lens, the phenomenon will be reversed: the central parts will become red, and the borders violet.

Masked by the great quantity of white light resulting from the mixture of a large number of rays of different colours, this arrangement will really be apparent to the eye only upon the borders of the field, but, as we shall see, it exists nevertheless in every part of it.

Let us take a crown illuminating lens, of which the focal distance of the red ray is thirty centimètres, we shall see that, for the violet rays, this distance will be only twenty-seven centimètres. The mean rays are found comprised, at unequal distances, between these two points.

For an amplifying apparatus, take a simple achromatic converging lens, and project upon a screen the enlarged image of the sun which is found in the focus of the collective lens. We have seen that on account of the dispersion this focus is not single, but comprised between two caustics of a certain length. If, therefore, we focus the most distant, which is consequently the most refracted, we shall have a red image of the sun upon the screen. Suppose this image is focussed at thirty centimètres, we shall see that, to obtain the same clearness for the violet image, we must bring the

screen five centimètres nearer to the amplifying lens — a position where only the violet ceases to be divergent. Now substitute in place of the screen a sensitised plate, also placed at thirty centimètres: the image that it will give will be a sort of target, composed of concentric rings of very different intensities. The central disc produced by the red, although it appears very luminous, will have but very feebly impressed the film, while the exterior zone, composed of the divergent violet light, will have given an opposite result; the intermediate zones will also have given their images in proportion to their chemical action. It is unnecessary to add, that if we have taken for the centre of the image the shortest, that is, the most refracted rays, the effect will be inverse, and we shall have a centre much more impressed than the borders. A negative, or any other object, composed of translucid and transparent parts, submitted to amplification in such a light, will give a proof unequally illuminated from the centre to the circumference,—the field being composed of concentric rings of different intensities.

We shall see that the inequality of the lighting is not the only inconvenience the convergent light presents. Two other phenomena also concur in this case to disturb the clearness of the images. When we wish to project a slightly-enlarged image of a small plane object by means of an objective in which the spherical aberration is well corrected, one thing at first surprises us—we cannot focus all the parts at once. The focus for the centre is much shorter than that for the circumference. This difficulty is explained by the effect of chromatic aberration, not by spherical. The field of light, as we have seen, is composed of zones of colours of unequal refrangibility: the object sends no specular light, and but little diffused light, because it is almost transparent; so that lighted in the centre by light transmitted red, starting from this point it is successively lighted by yellow, green, blue, and violet, the undulations of which have neither the same length, amplitude, or duration. The amplifying apparatus also shows us in this case that the field of light is only white light mixed with the tints resulting from dispersion.

With convergent or divergent light there are then no means of lighting or focussing equally from the centre to the circumference all the parts of an object of any size, and this is one reason why the solar microscope, as at present constructed, has remained an instrument of curiosity, and that without the modifications I have made in it it would be useless for photographic purposes.

It remains to demonstrate that a third cause of disturbance, and one of the most important, also results from the convergent lighting. To avoid complicating the question, and to confine ourselves within the practical limits of superficial enlarging of five or six times, we shall admit that the convergent rays which emerge from the collecting lens are white light. In examining these rays after interposing a parallel glass in their path, we see that the caustics which limit their focus are much lengthened, while at the same time the field of light changes its aspect. We now encounter the phenomenon of interference. From the centre, where the refraction is *nil*, unto the circumference, where it is at its maximum, the pencils fall upon the glass with very different incidences, so that upon their emergence the relation between their sinus of refraction and their incidence is changed: they then proceed in a less parallel direction together, and interfere with each other before arriving at the focus. The final result is a new disturbance in the equality of the lighting, which is also complicated by the fact that the glass that sustains the film has never parallel faces.

It is only necessary to substitute a microscopic object for the transparent glass to recognise the influence of this new cause of perturbation. Fringes of diffraction form upon all the contours; the details are vague, the lines faint, blurred, and multiplied.

It is said that a convergent lighting is the only condition which admits of the employment of all the transmitted light; and the reason assigned is, that the focus of the lighting cone is found upon the optical axis of the amplifying apparatus, or rather upon the first lens of the doublet of which it is composed.

To become satisfied, on the contrary, that this luminous point is of more harm than good, we have only to fasten a wafer in the centre of the first lens, where the collective lens has its focus: the image is immediately improved. Finally, let us follow the path of the light in the amplifying apparatus as we have done in the lighting. What is this luminous point? It is the image of the sun, which I suppose to be single, although the convergent lens, not being achromatic, gives a good many. It does not contain the miniature image of the negative, as might be supposed, for the light of this point to be efficacious. On the contrary, it results from the union in the focus of all the pencils which have traversed the transparent parts of the glass.

To examine what will be the effect let us imagine a case. This image will be nearer or farther from the principal focus of the doublet of which the objective is composed, or rather it will coincide with this focus. In this case it will give upon the screen a bundle of parallel rays or a smaller disc than the field of light necessary to illuminate the negative. If farther, as the principal focus is enlarged only by one of the lenses of long focus composing the objective, it will form a round image of the sun in the midst of the amplified negative; if nearer, a bundle of divergent rays which will cover the projected image with a luminous veil. Far from strengthening the effective light, it will serve only to veil the proof and make it less vigorous. From what we know of interferences we may say that, penetrating the apparatus under a different incidence from that of the light transmitted by the negative, it is the cause of a supplementary diffraction.

The study I have for a long time made upon the influence of the lighting upon the clearness of the results would, nevertheless, not have led me to make these remarks, if I were not prepared to propose a simple means of diminishing the inconveniences of the convergent light, otherwise scarcely evident in practice in the slight enlargements employed. I should not have pointed out these sources of troubles if it were necessary to have recourse to expensive instruments to remove them. Understanding that, between an apparatus intended for superficial enlargements of ten or fifteen times and one for lighting objects enlarged a million times, there must be a very considerable difference, I should have said nothing about them if I had not thought they could have been rectified without expense.

I have contrived an instrument which, like the solar microscope, is composed of a reflector moving in two planes, intersecting each other in such a manner as to permit at any moment the bringing the sun into the optical axis; of a plano-convex lens; and of a concave lens of variable diameter and focus for three positions. This lens, of the same dispersive power as the first, is calculated, in its diameter and vertical focus, for the place it must occupy in the convergent cone, the rays of which it is intended to render parallel at their emergence.

To lose none of the light transmitted, and to concentrate upon the negative all the parallel light sent by the reflector upon the whole surface of the collective lens, I have made three negative lenses for changing; the operator is therefore enabled to limit the diameter of the bundle of rays parallel to that of the negative to be enlarged. By these means we see that, in the limits of practice, no part of the incident light is lost. The intensity of the bundle of rays is in the inverse ratio of the square of the diameters of the negative lenses employed; thus there is the advantage of making use of that upon the surface of which the negative may be placed.

In the conditions of parallelism in which I place myself, both at the entrance and upon the departure, the rays in their passage through the plate suffer no refraction, and the interference of this latter produces no modification. Experience has long demonstrated to me that, with this light, most of the disturbing phenomena disappear, as the focussing is more exact, and the aberration less evident; and lastly, the fringes of diffraction only begin to appear at a distance ten times greater than with convergent light, that is to say, with enlargements a hundred times greater. Still, although presenting advantages over convergent lighting, which appear to me indisputable for the end proposed, in very delicate experiments, and when we endeavour to obtain an image of which the superficial dimensions are magnified five to six hundred thousand times, they give rise to effects which do not admit of their being employed.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this Society was held on Tuesday evening, the 1st instant, in the Library of King's College, — Henry White, Esq., in the chair.

The Chairman, on taking his seat, stated that it had been fully anticipated that their President, the Lord Chief Baron Sir Frederick Pollock, would have presided on the occasion of the Society's first meeting at their new rooms in King's College; but, as his Lordship had not arrived by half-past eight, he had been requested to take the chair.

The minutes of the last meeting having been read and confirmed, Captain R. L. Playfair and George Lowie, Esq., were duly elected members.

Mr. Shadbolt exhibited two views of Trinity College, Dublin, taken by Mr. Grubb, with an aplanatic lens of nine inches focus, which included an angle of 60°.

Mr. Hardwich then read a paper *On the Value of Collodion as a Photographic Agent.* [See page 142.]

After the reading of the paper had been concluded,

The Chairman suggested that the discussion on the Collodion Report should then be proceeded with; and as Mr. Malone had formerly expressed a wish that that subject should be discussed that evening, perhaps he would favour the meeting with his views.

Mr. Malone observed that, with such an appeal, he could not refuse to rise; but he begged to state that although he had been anxious that the report should be fully discussed, yet he was not anxious to commence the discussion. If his memory were correct, it was Mr. Mayall who at the last meeting proposed that the discussion should be re-opened, and he (Mr. Malone) certainly expected to see Mr. Mayall present that evening. That gentleman's absence had placed him (Mr. Malone) rather in a difficult position, as he was there to defend the report, and nothing had as yet been said on either side. He should therefore place himself entirely in the hands of the meeting, and thought he could not do better than sit down, expressing his willingness to rise at a later period in case anything should be said which might call for a reply from him.

Mr. Heath expressed his unwillingness to commence the discussion, and rose to suggest that some mistake had arisen as to the day, for Mr. Mayall distinctly moved the adjournment of the discussion, and assuredly he was not the man to exhibit any disrespect towards the Society. There was a conviction in the minds of many that there must be a mistake as to the day, or that some other cause had prevented his and, perhaps, the Lord Chief Baron's attendance. Under the circumstances he begged to put the question, whether the meeting could not extend its indulgence to Mr. Mayall, and again postpone the discussion?

The Chairman considered that as it was the last meeting but one of the season, and as Mr. Hardwich was present to meet all comers, and likewise that there were many gentlemen present for the purpose of hearing the proposed discussion, it could not be further postponed. He saw Mr. Williams present, and as he was a practical chemist he should like to hear his opinions as to Mr. Hardwich's formula.

Mr. Williams said he had tried Mr. Hardwich's formula. He mixed the acids in the proportions, and according to the directions as to temperature, &c., given; but, when he placed the cotton in the liquid, it dissolved entirely. He knew that Mr. Hockin and other persons had also tried the process, and they had also failed. Mr. Hardwich might possibly be able to explain the cause of their failure. He could say that the proportions were totally different in Mr. Hardwich's formula from those which he had ever employed, and therefore it was quite possible he had entered upon the experiment with some little prejudice against the formula. His own mode of operation was to mix

40 oz. sulphuric acid ..............................S.G. 1·846
64 oz. nitric acid .... ,, 1·45

the temperature would then show about 115° Fahrenheit. Eight ounces of cotton then to be immersed, and the vessel containing the whole submitted to the action of a sand bath until the temperature became elevated to 160° Fahrenheit, when the operation is stopped,—the time occupied varying from ten to twenty minutes.

Mr. Malone said, after the important phase the discussion had assumed in consequence of Mr. Williams's statement, he (Mr. Malone) considered himself justified in rising to state his own experience, which was quite of an opposite character. The very first time he tried he succeeded perfectly; but there was an extraordinary discrepancy between Mr. Williams's experience and his own, and in order to prevent any possibility of mistake he would state exactly what he did. He took one measure, viz., one fluid ounce of nitric acid, and ascertained the specific gravity of the acid, first proving his specific gravity bottle to ascertain that it was perfectly correct, for that was a matter of very great importance. He had even taken the pains to weigh water into the ounce measure which he used, and in doing so he found that it only held seven drachms, or one drachm less than it ought to do. Nothing was more common than errors of this kind in the measures ordinarily employed; and he might here observe that it was of the utmost importance, in conducting delicate operations like the present, that the apparatus employed should be carefully tested before being used, for that error alone was sufficient to cause failure in every trial. Then, having weighed just one fluid ounce of nitric acid—the specific gravity of which was stated to be 1·446, but which, by actual experiment made with the very accurate balance in the laboratory of the London Institution, he found to be a little higher, say 1·447 or 1·448. To this he added three fluid ounces of sulphuric acid, of the specific gravity of 1·842 or 1·844. The consequence was, that the acids were weaker than those recommended by Mr. Hardwich. Having mixed the acids in the proportion of one to three by volume, seven fluid drachms of water were added. The actual temperature of this mixture was fully 180° Fahrenheit. The acids were then allowed to cool down to 150° by one thermometer and 148° by another thermometer, which was nearer the truth. He mentioned these figures to show that his experiment was not one of chance, but that every point was accurately determined; and operators might be assured that unless they took similar precautions they would be liable to be misled. Well, then, with this mixture at 148°, he placed in it fifty grains of cotton, which had been previously treated with an alkaline solution, washed, and dried. After remaining in ten minutes the temperature was reduced some 3° or 4°. The cotton was then taken out and well washed in plenty of water. The whole process was the simplest matter in the world. He obtained sixty-eight grains, which he produced, and he was told he ought to be satisfied if he got fifty grains. Yet Mr. Williams and others had absolutely obtained nothing, the whole of the cotton being dissolved by the acid! How was that to be accounted for? He (Mr. Malone) could give no explanation of such an extraordinary discrepancy. No doubt the managers of the London Institution would allow their laboratory to be used for the purpose, as they had done on other occasions; and he would be happy to repeat his experiments before any competent person who might wish to investigate the subject, in order to place the matter beyond dispute. His success was not owing to his intercourse with Mr. Hardwich, although Mr. Hardwich had been very kind in the matter. He was convinced that any one could obtain the same result by taking the same precautions. Chemists knew that the action of these acids at a given temperature upon a given body was a definite action, and it was impossible it could be otherwise. Possibly the cause of the failure of Mr. Williams's experiments might be in the cotton, as that was an article which varied much in character. It was a matter of considerable difficulty to determine what was cellulose. He said that Messrs. Gilbert and Law, recently writing upon agricultural chemistry, had defined cellulose in rather a singular manner: they said that all vegetable substances which did not give way under acids might be regarded as woody fibre, and all that did give way might be regarded as the portion which constituted the food of animals. The substance used for the base of collodion not being definite, Mr. Hardwich had done the only thing he could do under the circumstances. He had said that he took a certain cotton, which he bought at a particular shop, which was of a particular growth; and he had told them at the same time that he had found cotton to vary as to the place at which it was grown, and even flax did so. It was to be borne in mind, also, that he could not tell when he obtained a piece of cotton how far it might be affected by oil or other impurities. Chemists could not take anything for granted; but, when they wished to secure successful results, they should treat the cotton with alkalies, in order to get it as definite as possible before using it. If, for instance, cotton were treated with caustic potash, and showed a yellow colour, the result would be that it would not dissolve in acids which otherwise would have dissolved it. In the experiments named by Mr. Williams it was possible that the cotton might be wrong, or it might be improperly cleansed, or it might have been imperfectly dried after cleansing, which was a very important matter, or there might be an error in the strength of the acids: it was impossible for him to determine which was the case of failure—it might be any or every one of these causes combined. The process was a very nice one, but with good and proper instruments it was easily worked. Mr. Malone, resuming the subject of his own experiments, said the cotton remained in the acids ten minutes. On taking it out it was tested with one of Mr. Newman's thermometers; and he might observe that a standard thermometer was a very valuable instrument, and he believed that Mr. Newman valued his thermometers at twenty guineas each. Although he did not recommend members to give twenty guineas for a thermometer, yet he recommended them to have their thermometers compared with a standard thermometer, for doing which there was an arrangement at Kew Observatory. Mr. Malone then exhibited some of his pyroxyline, which he remarked was not particularly rotten, and it cohered well. He took five grains of this cotton—put it to half an ounce of alcohol of the specific gravity of 0·806, distilled off chloride of calcium, and half-an-ounce of ether of the specific gravity of 0·725. Although in the manufacture it was not necessary to have everything absolutely pure, still if the acid or ether contained oxidised or ozonised particles the result would be unsatisfactory. The ether, a very good chemist had told him, should be neutral, but Mr. Hardwich believed that the ether ought to be alkaline; and at last he had found it so in all samples he had employed. The cotton was washed some hours in ordinary water—of course theoretically he should recommend distilled water, yet in practice he did not find it to be necessary; and he agreed with Mr. Hardwich that it was not desirable unnecessarily to refine upon a process. The five grains of pyroxyline being dissolved in alcohol of the specific gravity of ·805 or ·806, and ether ·725, he had added two grains of iodide of potassium and two grains of iodide of cadmium; and here he remarked that all chemicals were not to be found of the best quality at one place—for instance, if the best iodide of potassium were to be obtained at a certain house, it might be necessary to go elsewhere for the iodide of cadmium. He made that remark, not for the purpose of over-refining, but to show those at the head of the trade the importance of not leaving these matters entirely to assistants. At the same time, it must be remarked that amateurs must be prepared to pay the best price for the best articles. Mr. Malone then demonstrated to the Society that the pyroxyline which he had prepared was perfectly soluble in some ether and alcohol which he had brought with him. He then observed that the collodion which he thus obtained made a perfectly clear and tenacious film. Such was the result obtained by the formula which had been made public by the communication of Mr. Hardwich, and which he considered to be of great importance to the photographic world, notwithstanding the entertainment of a contrary opinion by other persons. Because the committee entertained a high opinion of Mr. Hardwich's collodion, and had given it the stamp of their approval, a neighbouring Society had thought fit to take the Photographic Society to task, alleging that its members did not know what they were

about. Mr. Malone would then tell that neighbouring Society that they knew perfectly well what they were about. No one had given the minute information respecting the manufacture of collodion which Mr. Hardwich had done, and by which he (Mr. Malone) had been enabled to make an excellent collodion, as might any other person. He must confess he believed Mr. Hardwich had been incited to obtain a perfect formula because he had felt rather galled at the remarks which had been made some few years since. Another maker of collodion, for instance, had said, "If it were not for my collodion, photographers might shut up shop." No doubt that gentleman was very lucky to have hit upon a good collodion "by rule of thumb;" but, if he were to shut up shop tomorrow, photographers would still be able to obtain a very good collodion by the process now published by Mr. Hardwich. Mr. Malone did not recommend all photographers to make their own collodion—on the contrary, he recommended them to go to a respectable maker; but the importance of the formula was not lessened because it was not desirable for each individual to become his own collodion manufacturer. The reason the Society published the report was that they found a really good thing, and were desirous of making it public. It was not for him to speak on behalf of the Committee, but he ventured to think, with regard to the other formulæ sent in, that they had acted kindly by *not* bringing forward all the points that struck them. The other formulæ sent in were imperfect. There was one in which the author had not quite made up his mind as to his formula, but recommended the Committee to try this or that. Surely this was not the business of the Committee: the gentlemen composing that body had not time to devote to the task of perfecting a person's imperfect formula. They had simply to inquire into the characteristics of formulæ as they were presented to them. Another formula sent in contained a fundamental objection. He believed that any formula that recommended paper as a base ought not to be received or considered. The gentleman who sent it in said, if they took Swedish filtering paper they would obtain what chemists knew to be a good cellulose. Any person acquainted with the manufacture of paper, as he (Mr. Malone) happened to be in the early period of his life, knew perfectly well that it was impossible for any person to tell what were the constituents of a piece of paper, and how far they might differ from another piece nominally of the same manufacture; in fact, it was a heterogeneous mass, some portions of which were soluble and others not. He knew an instance of a gentleman who had succeeded perfectly in making collodion with some Swedish paper, but upon taking another batch of the same manufacture, and treating it in precisely the same manner, he entirely failed. With regard to the sensitiveness of Mr. Hardwich's collodion various observations had been made, and even in the body of the report one gentleman stated that he had obtained a collodion twice as sensitive as that of Mr. Hardwich. The Committee had been taken to task for the contradictory nature of the report, but the apparent contradiction to which exception had been taken only showed the honesty with which the Committee had conducted its investigation. He (Mr. Malone) did not doubt for a moment but that Mr. Heath had stated what he believed to be true, but had he shown such a collodion as to be twice as sensitive as Mr. Hardwich's? Could he show it? He (Mr. Malone) thought he could not. If such a collodion could be obtained, it would have been advertised from one end of London to the other. He was anxious that Mr. Hardwich's labours should be properly appreciated: he had given them very important facts, and a collodion, he would not say better, but he would say as good as any other that could be procured. If manufacturers of collodion were candid, they would admit that they frequently found difficulties unexpectedly arising from the uncertainty of their process. He believed that Mr. Hardwich had given the clue to a means of producing this article with something like certainty; and, if so, he had conferred a very great boon upon the photographic public. He (Mr. Malone) was sure that the Committee would be happy to take into consideration any formula that might be presented by any competent experimenter.

Mr. HARDWICH wished, at this state of the proceedings, to remark that he should be exceedingly sorry to think that this was a formula that any practical man could not succeed with. He thought he was justified in stating that Mr. Williams had written to him, and had told him that his time was very much occupied in the manufacture of various chemicals, and that he had given his (Mr. Hardwich's) formula for making collodion a trial once, and it broke down. He had heard Mr. Hockin's name mentioned as one of those who had failed with his formula. He believed that Mr. Hockin himself had a process for making collodion which he possibly considered a better one. If not, probably he would have succeeded. He was very sorry that it should go forth in print that his process had been tried and failed. Mr. Malone had tested the formula in a very philosophical manner, and with successful results; but he was sure Mr. Malone did not wish to convey the impression that success was only obtainable by these extraordinary precautions. Everything which had been published about this formula as yet was against it; but the meeting was not to suppose that no one had been successful. He (Mr. Hardwich) had received letters reporting success on the first trial; but, whereas failures generally found their way into print, successes were seldom reported. The question, he apprehended, for the Society to consider was, whether his formula gave better and more certain results than any other published formula? If it did not, then they should cease to trouble themselves about it. The manipulation required care, but not more than a maker who desired to produce the article would be willing to give. The question had been put to him by Mr. Williams, Why did the cotton dissolve in the acids? If the whole of the cotton dissolved, he should say that more water had been employed than the formula indicated; but if only a part of the cotton disappeared, and, say only a quarter could be got out, this might depend upon the cotton being imperfectly cleaned, or upon the acids being contaminated with chlorine. He found that the more water he used in the acids *up to a certain point*, the better was the collodion. If made with less water some small defects—perhaps a streak here and there that interfered with the perfect uniformity of the background, such as the amateur did not see, but which the professional photographer did see—were apt to occur. In fact, the amateur might obtain a very respectable collodion, and with greater certainty, by using less water than was recommended in the formula given. He had purposely allowed for a range between the maximum and minimum of water in drawing up the formula. The question, he repeated, for the consideration of the Society was simply whether the formula was worth the trouble which had been bestowed upon it?

Mr. WILLIAMS said that his experiment certainly was not made with that care which he should have taken had he known that he would have been called upon to express an opinion on the formula. He only stated his experience because the Chairman invited him to do so.

Mr. MALONE said that if his remarks had appeared unusually warm, they were so because persons had stigmatised the Society elsewhere, and even in its own Journal, in a most extraordinary manner.

Mr. HEATH said it might be his misfortune that it had fallen to his lot to originate this discussion. He had, on a previous occasion, used expressions which he trusted were perfectly friendly to Mr. Hardwich, and conveyed in a tone which he hoped he should always use in that room, but which the circumstances fully justified; consequently, the remarks Mr. Malone had made did not apply to him—("No, no," from Mr. Malone). At the same time, he was compelled to say that he saw no reason, from anything which had since transpired, to alter one single expression he had used on that occasion. He believed this subject was still misunderstood. He entertained the highest opinion of Mr. Hardwich's collodion; but he remembered how that Committee was formed, in the first instance—not to consider the best method of making collodion, but to consider Mr. Hardwich's collodion. ("No, no.") Such, he believed, was the case.

Mr. MALONE acknowledged that that was the original intention of the Committee; but it was modified, so as to admit other collodions.

Mr. HEATH asked why this resolution was afterwards modified? because it was found that it could not be entertained in its original form. And if so, why was Mr. Hardwich's collodion placed in such a prominent position in the report? He would ask Mr. Malone if it were at all likely that men whose business it was to manufacture collodion would come forward and publish their formulæ? It did not follow that, because Mr. Hardwich's collodion was good, that other collodions were not so. If the injustice done to other manufacturers in the report, by the grammatical error of employing the comparative degree where no comparison had been made, could be altered, and if the report could be regarded as only conveying the opinions of the gentlemen who signed it, and not as pledging the Society to the opinion expressed in the report, then let it remain on the transactions of the Society, and let the Society at once make all the acknowledgments that were due to Mr. Hardwich for his painstaking experiments. He (Mr. Heath) would never use that room to vaunt the names of other collodion manufacturers; but Mr. Malone, in speaking of the sensitiveness of Mr. Hardwich's collodion, had thrown down the gauntlet. He (Mr. Heath) would take it up, and he would undertake to prove to Mr. Malone any time he pleased, that there was a collodion in the market not only two-to-one, but three-to-one more sensitive than that of Mr. Hardwich's.

Mr. MALONE admitted that he thought the report was open to verbal criticism, and in Committee he had suggested one or two verbal alterations. Thus, the term "superior excellence" had been objected to, and possibly a more guarded expression might have been employed; but if it were said of any gentleman present that he was a man of "superior mind," did it follow that he was to be regarded as the best man in the assembly? And yet that was the construction attempted to be put upon the expression used in the report. The report really only attempted to convey the truth, in stating that the collodion was of superior excellence. He must say that he was no believer in universal collodion; he believed that it would have to be modified to suit the particular work and season. But as a normal collodion, he knew of none equal to that of Mr. Hardwich. He did not wish to speak disingenuously, but he was only speaking the truth when he said that the strongest opposition to the report came from parties who were personally intimate with the makers of other collodions; therefore, it was perhaps excusable that gentlemen whose interests might be touched should scrutinise the report very closely. He thought that the Society ought to come to a decision that evening, and accept the report; and that the Committee ought to be thanked for the pains they had taken and the desire they had shown to investigate the formula that was brought before them. He thought Mr. Williams would confirm his statement, that photographic investigations would assist chemical science. When he first went to the College of Chemistry, he was told that ammonia did not precipitate oxide of silver. This was contrary to his photographic experience; and he found that the statement arose because a very weak solution of silver had been usually employed for analytical work in the laboratory, so that

the oxide was dissolved as fast as it was precipitated, which would not be the case if strong solution of silver were used. Again, it was stated, by an authority, that ether ought to be neutral; and yet Mr. Hardwich always found that it proved alkaline. With regard to the challenge of Mr. Heath, he was astonished at the statement that there was a collodion three times more sensitive than that of Mr. Hardwich; and could not understand why he had not brought that collodion before the Committee. He accepted the challenge, but he questioned whether Mr. Heath could produce such a collodion.

Mr. Heath asked Mr. Malone the real English of "unsurpassed sensitiveness," for that also appeared in the report.

Mr. Malone said that was answered by the same argument as he had used as to the "superior excellence."

The Chairman said he presided at the meeting of the committee at which the report was arranged. It was criticised verbally throughout, and was the result of the deliberation of all the members present, who spent two hours in settling the wording, and he believed they ought not to alter a single word. The arrangements for furnishing a report were these:—A committee agreed that its various members should work separately. At the end of the year they were requested by letter to send in their individual reports to Mr. Fenton, who drew up the draft of the report, incorporating the sentiments of the individual members. It was the opinion of the majority that the collodion was unsurpassed in sensitiveness. When the majority of the members said unsurpassed, they meant in regard to their previous experience; and if their opinion was favourable to Mr. Hardwich, he did not think that the trade, or Mr. Heath, or any one else had a right to find fault with it. Then the last sentence of the report was objected to. He did not think that the words "superior excellence" could with fairness be objected to. The expression was comparative, but not superlative. It was not thereby meant that the collodion was *the* best, but one of the best in the market. Of course it was not the interest of the Society to encourage secrets. If the manufacturers of collodion did not choose to compete or communicate their formulæ, the Society was open to obtain the best formula it could in which the whole process was described; and, if Mr. Hardwich was good enough to communicate his process, there was no impropriety in the Society receiving the report and stamping it with its approbation. He thought that the photographic world was as much indebted to Mr. Hardwich as it had formerly been to Mr. Archer. He did not interpret the report as Mr. Heath read it; and he, as a member of the Committee, did not feel disposed to alter a single word.

Mr. Hughes said he could hardly allow the occasion to pass without calling the attention of the meeting to the very emphatic observations made by Mr. Heath on a former occasion, and equally emphatic on this. In the report the individual opinions of the members were certainly fully expressed; but, whilst the expressions as to the merits of the collodion were only generally noticed, the faults discovered by each operator were specially pointed out: but this very candour of the report seemed to defeat its object, and it was called contradictory when it was only just. Mr. Heath upon a former occasion objected to the Committee being appointed.

Mr. Heath begged Mr. Hughes's pardon, and said "No."

Mr. Hughes had a most vivid remembrance of the words.

Mr. Heath said he did not object to the appointment of the Committee. His observation was, that the Committee was appointed for a distinct and specific purpose; and, because no other formulæ were sent but that from Mr. Hardwich, the object of its appointment could not be carried out, and therefore the Committee virtually ceased to exist.

Mr. Hughes understood Mr. Heath to say—first, that it never should have been appointed; next, that it should not have sent in its report; and, finally, that the report was contradictory. Now, supposing that the Committee had been appointed conditionally upon formulæ being sent in, and only one gentleman sent in such formula, and other samples were sent in without the formulæ, and the Committee had compared those various samples of collodion, or suppose they compared this collodion with others well known, what would be the consequence? If the report had been laudatory of any one of those collodions, it would clearly have been an advertisement for the maker; but, supposing that that individual maker had died, and taken his secret with him, where would have been the advantage to the photographic world? Or, on the other hand, supposing the Committee had condemned these other collodions, then the various manufacturers would have come forward, and have said, "Why did you condemn our particular collodion? We never courted your Committee. We held aloof from you, and why did not you hold aloof from us?" And now it was because the Committee did not report on other known collodions, the formulæ of which were not sent in, that this charge was made against it. The Committee, in justice to Mr. Hardwich, could do no otherwise than it did. Only one formula was before it,—was that one submitted to their notice by a gentleman likely to give a valuable one? He thought that there was no question on that point. On that Committee were some of the most distinguished photographers the world ever produced; and if a Committee of such a character met together, and gave their recorded observations of many months' work, and presented a report, he held that their opinions ought to be received with respect by any Society, and more particularly by that Society.

Mr. Hardwich said that at that late hour in the evening he would endeavour to be as brief as possible. He did not think that there were many in that room who could exactly understand his feelings in the matter. The discoverer of the collodion process was Mr. Archer, and what was being done now was simply to improve the details of his process. He (Mr. Hardwich) did not care about seeing his name in connection with the making of collodion; but he had been a maker for the last three years, had made large quantities, and had experienced many vexations. He had, for instance, sent collodion to India, and had received letters saying that when it had arrived there it was utterly useless. This sample had been made of linen. The same thing happened, though not with his collodion, to a gentleman travelling in the interior of Africa, to whom it occasioned a loss of six months after all his materials and apparatus were out there. He had consoled himself with the idea that the moment he had any formula that could honestly be reported upon he would lay it before the society. Had collodion been left in the position Mr. Archer had left it the data would be very unsatisfactory. The real truth was, that in collodion little matters were of the greatest consequence, and unless these were experimentally determined they would never have an article that could be depended on. He did not wish to set himself up as a martyr: on the contrary, he admitted he had been very successful commercially, and was perfectly satisfied; and now that he had settled the formula, he invited its examination by the society. If another manufacturer could produce a collodion three times as sensitive as his own, he should be exceedingly delighted, because such a collodion would be a great boon, and he would advise the Committee to take that collodion into consideration, even if the maker declined to publish the formula; but he must say, candidly, that at present he had a firm conviction in his own mind that that assertion could not be substantiated. If it could, he would be the first to praise it. It was not his intention to allude to the subject again, but he should keep a strict look-out upon what was doing; and if any one introduced an improvement, he should catch hold of it, and tack it on to his formula. He did not think any injury had been done by the discussion. He met some gentlemen the other day, who said that good collodion could be procured all over London, and were quite at a loss to understand why this Society should be taking so much trouble about a formula. The Committee, however, entertained a very different opinion. He could understand individual members entertaining objections to this movement, without attributing to them illiberal motives—("Hear, hear," from Mr. Heath). He did not consider the question of the manufacture of collodion could be settled till every minute particularity connected with the subject had been ascertained, and especially as to how samples would be affected in India, Africa, Australia, and other places. He allowed, then, there were weak points—as, for instance, the manufacture of ether. There were very few persons who made ether—not more than three or four—so that part of the subject rested with them. He thought if the Society spent £100 upon the investigation of the subject as to what ether was, it would not be wasted. They must find out the cause which makes some collodion, with the iodising solution, perfectly red. Then there were so many sorts of cotton, and, supposing those cottons to be equally cleansed, would they all agree in character? It was his impression that they would; but this had not been proved. All one could do was to go to the maker, and inquire into the growth of it. He believed if these two points were settled, the formula would be in a better position than it was at the present moment, and he was convinced the inquiry would result in good to the cause of photography.

The Chairman announced that, at the next meeting, Mr. Dallmeyer would read a paper *On Distortion, as Produced by the Present Form of Lenses, and on an Improved Description of Lens, Free from this Defect.*

The meeting was afterwards adjourned.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of the above Association was held at Myddleton Hall, Islington, on Wednesday, the 25th ult. George Shadbolt, V.P., occupied the chair.

Mr. Hill, Treasurer, officiated as Secretary, in the absence of Mr. J. Barnett.

The minutes of the last meeting having been read and confirmed,

Mr. George Dawson read a paper *On the Reaction of Chloride of Silver upon the Hyposulphite of Soda.* [See page 127, No. 117.] Mr. Dawson during the reading exhibited two halves of a stereographic print, produced by floating paper on the liquid alluded to in his paper, and demonstrated to consist of chloride of sodium *only* in solution, after the hypo. solution had been acted on by chloride of silver, as described. After being dried the paper was then sensitised on a nitrate of silver bath, exposed under a stereoscopic negative, and one half fixed by hypo. and the other by ammonia, the result being well-marked ordinary positive prints, thus serving as an *experimentum crucis* to the chemical tests employed.

After the conclusion of the paper, a general murmur of applause followed, and the Chairman remarked that it was unnecessary to propose the thanks of the meeting to Mr. Dawson for his paper, as they had been already spontaneously accorded. He observed that a paper like that they had just listened to left but little room for discussion, as it was so utterly conclusive; still the meeting would be glad to hear any observations upon it.

Mr. Hill inquired whether some test had not been suggested for detecting the presence of hyposulphite of soda?

Mr. Dawson considered that the testing was not of much importance with regard to paper photographs, inasmuch as if any hyposulphite were left in it, heating the print would by the scent evolved infallibly betray its presence. He mentioned the importance of having an alkaline fixing bath, in order to avoid the possible chance of sulphurisation, and adverted to the weakness of the solution employed by MM. Davanne and Girard.

The Chairman adverted to Mr. Maxwell Lyte's plan of diffusing chalk in the fixing bath.

A somewhat desultory though instructive conversation then ensued between Messrs. Barker, Hill, G. W. Simpson, and Dawson, on printing and toning generally, during which it was remarked that the successful use of the chloride of sodium solution, produced from the hyposulphite of soda by the reaction of the chloride of silver, as a salting solution for printing paper, was a most convincing proof of the absence of any hyposulphite solution remaining.

Mr. Hannaford demurred to this, and stated that he should have expected *a priori* that solution of hyposulphite of soda perfectly saturated with chloride of sodium, used as a salting solution for paper, which should be subsequently sensitised with nitrate of silver, would produce a print.

The Chairman thought that Mr. Hannaford probably had not been able to follow the reading of the paper closely, as he would have seen that the case supposed by him could not have occurred.

Mr. Hannaford explained that as a solution of cyanide of potassium, saturated with chloride of silver, could be used to prepare printing paper to be sensitised on a nitrate of silver bath, analogy would lead one to imagine that the same effect might follow with the hyposulphite of soda solution as the solvent.

The Chairman pointed out that the two cases were not analogous. Mr. Hannaford had forgotten, that in drying, the cyanide solution became decomposed, the cyanogen escaping in the form of hydrocyanic acid, leaving naught but the chloride of silver behind; whereas with hyposulphite of soda, even supposing it possible for it to be saturated with chloride of silver, the same reaction could not occur.

The following letter from the Secretary, who was absent from indisposition, was then read:—

April 25th, 1860.

Gentlemen,—I much regret that I cannot be with you this evening. I am suffering from an attack in the throat; my medical attendant prohibits my leaving the house. I intended asking a few questions respecting the extremely unsightly appearance of the portraits you will find in the minute book. The albumenised paper is old, the nitrate bath sixty grains to the ounce, new hypo., and used for those pictures only; it became quite discoloured: the gold I used was of the strength of one grain to six ounces distilled water, and no *soda*. Can this be the cause? You will see some of the pictures have an ungrained, mottled appearance, as though the size or albumen were decomposed. More flat, dead, dull, and unsightly prints I never produced, and the negative will and has produced some excellent and bold results.—I am, Gentlemen, yours, &c.

The Committee North London Photographic Association. J. Barnett.

The prints alluded to were then handed round, being, as described, dull, flat, and presenting the appearance of what Mr. Hughes called on a former occasion "measly spots," though evidently printed from good negatives.

Mr. Dawson demonstrated that the unsightly appearance was not due to sulphurisation by warming a print at the fire. After some discussion the opinion pretty unanimously expressed was, that some decomposition of the albumen may have arisen from keeping the paper long, the original practice of coagulating the albumen by heat having been abandoned by many manufacturers; that the time allowed on the nitrate bath might have been insufficient to convert all the chloride into chloride of silver, and at the same time leave a sufficient excess of free nitrate to produce a vigorous print; and, lastly, that the acid chloride of gold may have removed a portion of the starch in the paper, and the prints being probably removed *direct* from the toning to the fixing bath without an intermediate washing, the latter may have become decomposed by the acidity of the former.

The Chairman exhibited two proofs from negatives of Trinity College, Dublin, taken with an aplanatic lens (Mr. Grubb's) of nine inches focus, and covering a plate ten by eight inches, by which an angle of view of 60° was included. These excited considerable curiosity and attention.

Mr. Goslett exhibited some specimens of glass taken from an operating-room, showing a considerable darkening of the colour from exposure to light, as was manifest from the part which had been covered by the putty retaining its pristine colourless brilliancy.

The Chairman reminded the members that this fact had been pointed out by Mr. Forrest, of Liverpool, more than a year and a-half ago, and in precisely the same way. That gentleman had shown that some glass of ancient date, taken out of a window of a cathedral or other ecclesiastical edifice, had, where covered with the putty, kept its colour, while the exposed part was darkened to a surprising degree.

Mr. Goslett had not been aware of the fact having been before noted, and was pleased at the corroboration.

Mr. Hare exhibited one of his very portable folding stereoscopic bilens cameras, with box and several spare backs, similar to one shown at a previous meeting, but with a few more improvements adopted from observations which he had noted on the former occasion. The camera in its present form received general approval.

The following gentlemen were duly elected members of the Association, viz., Messrs. Francis Bedford, H. J. Godbold, King, and Bawtree.

Votes of thanks to Messrs. Dawson, Goslett, Hare, &c., having been passed, the meeting adjourned at an unusually late hour.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

This Society met in George Street Hall, on Tuesday, the 8th instant. The chair was occupied by the president, Sir David Brewster.

The following gentlemen were elected ordinary members:—Mr. Thomas Elder and Mr. R. Murray.

The Secretary then read a paper from Mons. A. Claudet, of London, *On Photography in its Relation to the Fine Arts*. [See page 146.]

After the reading of M. Claudet's paper,

Mr. C. J. Burnett read a few remarks *On Burning-in Photographs on Porcelain*. His remarks were supposed to be, that it was advantageous to this operation that in certain cases the muffle in which the burning-in is performed should be filled with hydrogen, or even carburetted hydrogen gas in lieu of common air. His principal remarks, however, were relative to some part which the Blackheath Society had taken in giving to Niepce de St. Victor the merit of applying uranium salts to photographic purposes, a merit which he considered due to himself.

Mr. Walker protested against Mr. Burnett's introducing such subjects, which were quite foreign to the subject he had announced as his paper.

Mr. Taylor said that he himself had no doubt as to the superior claims of Mr. Burnett in this matter; still he could not agree to such strongly-expressed opinions against the Blackheath Society, as he considered that that Society had, in a sensible and straightforward official letter, entirely set the matter at rest.

Mr. Tunny thought that it was the duty of the Society to see that no one appropriated the valuable discoveries of Mr. Burnett, to whom the Society lay under a debt of gratitude.

Sir David Brewster said that certainly the Society would protect its members in such matters, and that the best way would be to propose a small committee to investigate and report on the rival claims of Mr. Burnett and M. Niepce.

This suggestion was adopted, and the following gentlemen were appointed:—Messrs. Walker, Johnston, and Tunny.

The Chairman said he had a subject to bring before the Society. It was an invention of Mr. Walter Hardie, of Edinburgh, by which duplicate pictures could be taken for the stereoscope from a single picture—that is, a left eye view being given, a right eye view could be produced. Considering that there would be no time that evening to read the paper describing this invention, he would, if the Society agreed to adopt it as part of their proceedings, send the paper for publication along with the other transactions of the evening. This was agreed to.

The Secretary then read the Council's Annual Report, which was to the following effect:—

That on the termination of the fourth year of the Society's existence, they were happy in being able to report that during the past year the success which had hitherto attended the Society in all its departments had been fully maintained. An addition of upwards of twenty three members had been made to the roll of the Society,—an addition which included not only many enthusiastic and successful amateurs, but also some of the chief professional photographers in the kingdom. Nor was the list of members of the Society now confined to residents in this country; in India, as well as in different parts o Europe, the Society had members, who doubtless would be valuable contributors to the exhibitions and to the meeting of the Society.

The Society had sustained a great loss by the death of one of its most distinguished members, Professor George Wilson. Taking a lively interest in everything connected with the art, although not himself a practical photographer, he was ever ready to give to the Society the information which he possessed. The communications which from time to time he made to the Society were of the most valuable and suggestive kind; and there would be no doubt that, had he been spared to prosecute his researches, he would have done much to advance a knowledge of the chemistry of photography.

The Fourth Exhibition of the Society had been again held in the Exhibition Rooms of last year, No. 90, George Street. Although, from various causes, several members had been prevented from contributing as they had done on previous occasions, a larger collection of works was sent in than had ever before been received, several of the chief photographers in England contributing for the first time. For evidence of the excellence of the exhibition itself, the Council would refer to the various critiques which appeared in the newspapers and photographic journals. These, almost without exception, pronounced the exhibition to be greatly in advance of any previous exhibition, either in Edinburgh or elsewhere.

Excellent as the exhibition was, however, the profits arising from it, after clearing all expenses, although very considerable, had not been so great as those from the exhibition of last year. This the Council thought might be accounted for by the severity of the weather during the greater part of the period that the exhibition was open.

The Society's Medal had been this year awarded to Mr. H. P. Robinson and Mr. James Mudd, and the Maconochie Wellwood Prize to Mr. Thomas Rodger. It was believed that this award of the prizes had given general satisfaction.

During the past year several interesting and valuable papers had been read at the monthly meetings; and several new processes, and improvements on the processes already in use, had been brought before the Society. The most remarkable of these was the wort process for preserving the sensitiveness of collodion plates, which had been invented by Mr. Macnair; for which invention the Council would recommend that the Society should award a bronze medal to him.

Members of this Society had been supplied gratis during the past year with the *Journal of the Photographic Society*. The Council proposed that this arrangement should be continued, with this modification, that as some members did not care to have that Journal, such members should be supplied in lieu thereof with photographs of the same price, purchased at the next exhibition of the Society.

The Secretary, Mr. Kinnear, having expressed a wish to retire, the Council had secured the services of Mr. Adam, who they doubted not would fill the office in a satisfactory manner.

An abstract of the Treasurer's account was then read, which showed a balance in favour of the Society of £315 12s. 8d., the balance at the close of last year being £229 9s. 9d.

Sheriff Hallard said he had been requested to propose the following gentlemen as office-bearers for the ensuing year:—

President — Sir David Brewster.
Vice-Presidents — Horatio Ross and George Moir.
Secretary — A. F. Adam. | *Treasurer* — H. G. Watson.
Council —

Alex. Young Herries.	W. S. Elliot.
George Harvey.	W. Walker.
T. M. Raven.	C. Kinnear.
T. B. Johnston.	John Moffat.

Auditor — John Cay.

This was agreed to, and the meeting separated.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The last meeting for the session of this Society was held at the rooms of the Literary and Philosophical Society on Wednesday, the 2nd inst., —W. T. Mabley, Esq., in the chair.

The Hon. Secretary announced to the members that the Council had resolved to continue the usual monthly meetings of the Society throughout the summer, as many of the members had expressed a wish to have the opportunity of meeting each other all the year round.

Mr. A. Brothers said he wished to call the attention of the Hon. Secretary to the report of the proceedings of the last meeting in the organ of this Society,* which stated rather incorrectly some remarks he had made — namely, that he (Mr. Brothers) had found that the alkaline toning bath was very liable to remove the albumen from the paper. What he had said was, that an alkaline nitrate of silver bath was liable to dissolve the albumen, but he had found that by adding acetic acid the effect quite ceased.

The Chairman then called upon Professor Roscoe, who read a paper, entitled *Some Points Concerning the Measurement of the Chemical Action of Light.*

At the commencement Dr. Roscoe noticed the great importance of the establishment of an accurate means of measuring the chemically active rays, as a step towards attaining a knowledge of the fundamental laws regulating photo-chemical actions; of which, notwithstanding the great progress made in practical photography, we know as yet almost nothing. The principles upon which the chemical photometer depends were then explained, and experiments illustrating these principles were shown (see *Philosophical Transactions*, 1857, p. 355). As examples of the results obtained by the employment of this instrument, the method was described by which the amount of chemically active light emanating directly from the sun had been measured. It appears that at two different times on the same day the rays contained in direct sunlight are capable of producing equal chemical effects when the sun is at the same height above the horizon and the sky is cloudless; thus the chemical action produced by direct sunlight alone at nine A.M. and at three P.M., at eleven A.M. and one P.M., &c., is the same. The chemical action effected by the whole diffused daylight had been likewise measured, the amount produced at an equal distance before or after noon being likewise the same. These statements were only true where the whole of the direct sunlight or diffuse daylight from a perfectly cloudless sky was examined. Photographers working in covered rooms, with various aspects, must naturally arrive at totally different conclusions. The laws regulating the variation of the photo-chemical intensity of direct solar and diffused daylight with the height of the sun above the horizon was next pointed out. From these laws many most interesting conclusions could be drawn; thus, for instance, it was seen that at every point upon the earth's surface, where the sun did not rise beyond a certain height, the chemical action produced by the total diffuse light was, during a part of the day, greater than that produced by direct sunlight. When the sun rose beyond this height the direct sunlight effected a greater chemical action than the total diffuse daylight, and between these situations there was a time when the chemical energy of these two sources was equal: this point is called the phase of equal chemical intensity. As another instance of the results attained by the method in question, Professor Roscoe described the experiments made for the purpose of determining the amount of chemical action effected by the variously coloured rays of the solar spectrum, and by help of diagrams and experiments illustrated this part of the subject. He concluded his communication by urging the necessity of having a simple and accurate method for registering the daily and yearly variation of chemical light falling from the sun upon the earth, not only as affording to photography a great help, but as furnishing important data towards an entirely new field of meteorological research.

After a very animated and interesting discussion upon the subject of Dr. Roscoe's paper, a vote of thanks being passed to that gentleman and to the chairman, the proceedings terminated.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Society was held on Wednesday, the 9th instant. Mr. Griffiths, one of the Vice-Presidents, occupied the chair.

The minutes of the last meeting were read and confirmed.

A letter from the Honorary Secretary of the Manchester Photographic Society was read, requesting the assistance and co-operation of the Society in the exhibition of photographs about to be held at the Salford Royal Museum and Library, Peel Park. Several specimens were promised.

A discussion followed on the paper read by Mr. Griffiths at the last meeting, *On a New Dry Collodion Process.* [See page 111, No. 116.]

The members who expressed their opinions were much pleased with the result, except as regards loosening of the film, which some had experienced.

Mr. Green found, by mixing a small quantity of albumen with the milk, that that was obviated.

Mr. Griffiths explained that, as he named in his paper, a coating of varnish round the edge of the glass would prevent that defect, which was very liable to take place with some collodion; it might be done after developing, when the film was surface-dry, as the risk of splitting was greatest after using hypo. or cyanide for fixing. He had found the mixing of albumen with the milk to give a peculiar redness to the negative, which he would rather not have. He had intended to state to the meeting his views and opinions as to making photographic societies more generally useful; but he should content himself by giving an outline of them, leaving the next meeting to consider them more fully. He considered that every member should do something to add to the common fund of information; and he should like to see a register of every member's name, and the processes that he could work, so that when there was no very important business on hand the register should be brought out, and each member in turn give the mode he employed of working. Much discussion would follow which would be profitable to the members present.

Mr. Ashley afterwards described the way that he had worked in taking portraits by artificial light, and Mr. Fawcett also gave his mode. Both gentlemen promised to show to the next meeting specimens of their productions.

A vote of thanks to the Chairman concluded the business.

CITY OF GLASGOW AND WEST OF SCOTLAND PHOTOGRAPHIC SOCIETY.

The third ordinary meeting of the above Society was held on Thursday evening, the 3rd instant. The President, J. Kibble, Esq., occupied the chair.

The minutes of last meeting having been read, and five new members ballotted for and unanimously admitted, the President read a paper *On the Influence of Light and Heat in Changing the Physical Properties of Bodies.* [See page 144.]

A short conversation followed the reading of the paper.

Mr. Bowman exhibited a dark cell for non-reversed pictures, which he had found to answer the purpose remarkably well.

Three highly-coloured miniatures on ivory were submitted to the meeting, and were much admired. These had been printed by Mr. Stuart's process (which he described at last meeting).

A vote of thanks having been awarded to Mr. Kibble for his most interesting paper, the Chairman intimated that, in consequence of the recess, the next meeting would not be held till the first Thursday of October. The meeting then terminated.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

If your photograph should chance to be one of those dull specimens which would destroy the purity and character of the transparent flesh-wash recommended, adopt another, composed of madder-pink and pale lemon-yellow or Naples yellow (the first is the better because most permanent), and then proceed to hatch upon this with the tint of the first wash, &c., as described. This second wash being semi-opaque, will cover and kill the grey tint of a bad or indifferent photograph better than the wash of purely transparent colours. If Naples yellow be adopted, you must remember that there are two preparations of this pigment — the one cold and greenish, the other warm — named respectively No. 1 and No. 2. The warm is the better for flesh tints; but if you use the cold for the wash in question, it must be corrected with a larger proportion of madder-pink. Beginners should use the warm. At this stage your photograph should be but faintly tinged with colour, and if the colours appear too positive or strong reduce them by working upon the surface with *pure* water only; or wash them partially off with a *soft* clean brush and water, using blotting paper to absorb the superfluous moisture — adopting the latter plan if all the colours applied are too powerful, and the former if such is the case in parts only. After washing off, the surface of the paper is sometimes found to be rubbed up; to harden and smooth which take an agate burnisher, and placing your print upon a sheet of polished plate glass, lay over the surface disturbed a piece of *clean* smooth writing paper, and firmly, and with an even steady pressure, rub it down with the burnisher until it is again glossy and hard. The

* Our report being an "official" one, the MS. copy furnished to us is of course our guide in the matter. We are not therefore personally responsible for the error noticed. —Ed.

burnisher may of course be used for this purpose whenever necessary. To such colourists as labour long at a picture, or wash frequently, it is indispensable.

THE GREYS.*

(See Maxims 41, 43, 13, 19, 16, 39, 32, 37, 54, 55, 56.)

Now mix a little Indian yellow and cobalt, using just enough of the former to give the latter a *slightly* greenish effect, and with this hatch over such of the demi-tints as by careful attention in examining your model you find assimilate to the hue obtained in working with this over the corresponding tints of your photograph. Here, as before, substitute the more opaque lemon or Naples yellow for specimens which are either bad ones, too dark, or ill-printed. In this and all other directions for compounding the tints of flesh (more especially the greys), you must consult your model, inasmuch as they not only invariably differ in different complexions, but also in their different positions. Where the skin is yellow they are most green; where whiter, most blue; where ruddy, most purple; where pink, of a violet hue, &c.; but in all parts of the flesh they abound.

Having worked in this slightly-greenish grey, take next a little ochre, cobalt, and madder-pink for such greys as are to be found upon the edges of shadows or upon the retiring surfaces. The same mixture will be useful in softening the eyebrows into the flesh, and working near or upon the outline of hair which cuts against the brow or cheek. On the cheek, owing to the presence of the carnation, the grey will be composed of cobalt and pink-madder; and the same hue may be used in rounding that part of the chin which is pinky in colour: it may also be selected for the half-tints of the eyelids, and used near that corner of the eye which is nearest the nose, on the receding outline of the nose itself, &c., as due examination of your model may decide. A little more or less of the pink or blue will be used in this mixture according to the effect desired, and sometimes a little Indian yellow may be added to destroy to some extent the purplish tone. In applying these colours, the tints covered having their part in securing the desirable effects, you must not use them unmodified for putting in half-tints which, although not secured in the photograph, exist in nature.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

Miss D., Kingsland.—I am sorry to say you have failed; but you must not forget that in undertaking the management of such a large mass of flesh you had a task of extreme difficulty. In addition to my own remarks, read these by G. Barnard:—"But there are other causes that influence this delicate study [that of flesh]. These are, the gloss or oily smoothness of the skin; the almost imperceptible down with which it is covered, but which produces a greyish tint; and the semi-transparency of the surface skin, showing the light through, as well as the blue veins, whether in light or shade. This effect of transparency or transmitted light has considerable power, as may be proved by tearing an orange in half, and looking at the pulp in shadow and in light—the deepest colour will still be deepened and greyed orange or crimson. The same with the shadow between the petals of a rose, or between rosy fingers, which no one would think of painting green. The colour of shadow must therefore be influenced by the part in light and the colour it assumes." This quotation will point out your sins of omission and commission more effectually than a few critical remarks upon your picture, and will at the same time be useful to others.

A. S.—If you must put in such pretentious landscape backgrounds you should at least know something about linear and aërial perspective, the symetrical arrangement of lines, the laws of *chiar'scuro* and harmonious colouring, &c., otherwise you will merely offend the eye of every tasteful observer, and destroy your picture's value. The importance of such a study should be obvious, for all your labour will be misdirected and vain without its aid. You must not expect me to write an essay on æsthetics in order that I may induce you to give attention to a subject the importance of which is admitted by all authorities, and instinctively recognised even by those totally ignorant of its theory. Lines must be as judiciously balanced as masses of colour and light and shadow. I would advise you (and all photographers) to give serious attention to the subject of composition and *chiar'scuro*.—See the works of Burnett, Sir Joshua Reynolds, &c.

Foreign Correspondence.

Paris, May 10, 1860.

M. Niepce de Saint Victor, continuing to persevere with his studies upon the persistent activity of light, has just published another experiment bearing upon the great question of "bottled light," undertaken with the view of ascertaining how long a time light would retain its activity in darkness.

In this experiment M. Niepce opened a tin tube, which was soldered up on the 4th of June last (1859). The interior of this tube was lined with cardboard, impregnated with tartaric acid (any other organic acid gives the same result), then exposed for some hours to the light of the sun. The cardboard inclosed within the tin tube was covered, and the cover soldered down. M. Niepce observed that the soldering was imperfect, admitting the light. In this state the tube has been kept (in the dark?) eleven months. Immediately upon its being opened, M. Niepce threw some drops of a solution of nitrate of silver into the tube, and closed it again. The tube being re-opened in a few minutes, the nitrate of silver was found blackened, forming spots of great intensity upon the cardboard. It appears from this that not only the luminous activity acquired by the cardboard impregnated with tartaric acid is retained for this long space of time, but also that it has lost nothing of its power; the reduction of the silver was as prompt and complete as when a tube is opened after the lapse of a few days.

One of our most accomplished photographers has announced the following method of obtaining direct transparent positives:—Take a collodion iodised with iodide of cadmium, sensitise in a silver bath of the strength of thirty grains to the ounce, dissolve in this bath, little by little, as much iodide of cadmium as it will take up; immerse the collodion plate in it as usual, then expose in the camera double the time required for a negative, and develop with pyrogallic acid: the image will come out as a positive instead of a negative. If this process prove satisfactory in other hands, it will recommend itself for its extreme simplicity and great facility of execution, which abridges the manipulations in a most remarkable manner.

M. Poitevin, whose name is so favourably known in connection with many ingenious suggestions in photography, particularly with photo-lithography, has lately announced a new collodion process, which has the remarkable feature of suppressing the nitrate bath. He uses an alcoholic collodion, to which he adds four to five per cent. of crystallised nitrate of silver, or about twenty to thirty grains to the ounce of collodion. When the plate is coated with this, pour over it a solution of iodide of potassium of the strength of two or three per cent., to which iodide of silver is added nearly to saturation. The plate is then washed freely and dried. When made ready for the camera, a solution of nitrate of silver is poured over the plate, which, when drained, is put into the slide, and exposed as usual. If this process be found practicable, it will take rank among dry processes. J. P.

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

CHECKMATE.

To the Editor.

Sir,—My last communication would be incomplete without taking some notice of the attempt of that party, to whose "good nature" (?) I am, *according to his own account*, so much indebted, to impugn the accuracy of the optical paper which I lately contributed to your Journal. I would first, however, say that, when he assumes that I have endeavoured to produce misapprehension with respect to the motives of his conduct, he assumes that which is not borne out by the facts. In my paper published in your number for March 15th last, I have confined myself as nearly as practicable to a simple statement of facts, which he has not attempted to disprove. If those facts be evidence that, while writing to me that the aplanatic lens had "precisely" the same distortion as the ordinary meniscus, he also wrote to Mr. Wilson, influencing him either to believe, or to continue in believing *the contrary*, and to publish that which he (the editor) knew, or thought he knew, to be incorrect, then has he (the editor), under the cloak of contributing truthful information, been playing false with both Mr. Wilson and his other readers. I believe that the foregoing must stand for *a deduction from facts, and not an endeavour "to produce misapprehension"* on my part.

Now, with respect to his last attack on my optical communications:—1st. He never reads them because they are unreadable. Answer: They have been read and understood by persons of still less mathematical knowledge than myself, and they have been read and approved by persons of far higher mathematical knowledge than necessarily appertains to a junior wrangler.

2nd. He writes:—"Mr. Grubb is now engaged in finding the optical centre of a combination of lenses;—rather a singular occupation considering that *combinations of lenses have no optical centre, and that the definition of that point only applies to a single lens.*" Answer: *That* I have been, or am, so engaged as he here states is exactly the reverse of truth, as my lately published paper fully bears witness. I would here observe that I have put in italics a portion of the foregoing extract from your

* Mr. C W. Day justly observes, in his cheap little work *On the Art of Miniature Painting*, that "in observing the colour of the human face the uneducated eye sees nothing more than the general or local colour, making no nice distinctions between shadows, 'demi-tints,' 'pearl' or 'grey tints:' yet such gradations and varieties do exist; and very much of what is called 'flesh-colour' is composed of purples and greys."

contemporary's essay, though not printed in italics in the original. My reason for so doing will appear by-and-by.

3rd. He extracts a sentence from my late optical paper having reference to the focus for parallel rays, and then writes:—"This is an erroneous statement as applied to any compound." Answer: My statement is not only perfectly correct, but it is consonant with what all *sound* writers on optics who have preceded me have stated, whose deductions are not to be overturned by an *ipse dixit*. But

4th. He attempts a proof of his *ipse dixit* after an old and perfectly illegitimate fashion of his own, viz., by interlarding words of his own, altering my proposition; and not only this, but he goes a step further, and *supplies a centre or point for his own convenience to measure from, which centre he has just before stated does not* (cannot) *exist*. [See the extract from his essay which goes before, and which I have marked in italics.]

5th. He states that if he happen to stumble upon a sentence of one of my optical papers, he is "nearly sure to find some erroneous statement made in it." Answer: This is an insult, aggravated by the circumstance that he made a similar and equally untrue statement some years since, and did not then, nor has he since, with all his assiduity, proved me in error in a single instance.

It is to *his* absurdly erroneous optics (not to mine), and his subsequent pertinacious defence of them, thus compelling me in my own defence to show who was wrong and who was right, that I am (so far as I am aware) solely indebted for his unscrupulous and continued hostility. How far his optics are more instructive now than years ago may be judged by a late sample. In one of his contemptible attempts to write down the aplanatic lens he states that I "facetiously" called it aplanatic. Why? *Because forsooth it is not aplanatic in the reverse position to that in which it is invariably to be used as a view lens!* Even a junior wrangler of Cambridge ought to have known that on the same grounds the aplanatic lens of a telescope is *as "facetiously"* called aplanatic. Does he mean to accuse Sir John Herschel (with whom I believe the term originated) of facetiousness in giving the title "aplanatic" to a lens which is only so in one position? or is he ignorant that no single (and probably no double) combination extant is aplanatic in both positions? Apparently he is, for I think he says so much of one of his own combinations, the aplanaticity of which, though asserted by him, rests merely on his "*ipse dixit*," contravened by another.

Fortunately the course which your contemporary has so long and with increasing perversity pursued ultimately works its own cure, and his (personal) optics must be strangely blinded if he see this not. The private communications which I occasionally receive—some from indifferent parties and entire strangers—show me that, while I need care little for the result of his tirades, he ought. Would that he saw this and studied his own interests better! I speak not as concerning myself alone. His fondness for abusing appears as too great to be lavished on the head of a solitary individual. It is not unfriendly advice to him to ponder his path ere it be too late. He who pursues an unworthy and mischievous course until he is no longer able to follow it, gets not much credit in the end for resigning it.—I am, yours, &c.

THOMAS GRUBB.

SYSTEMATIC INVESTIGATION OF DETAILS OF THE PROCESS OF POSITIVE PRINTING.

To the EDITOR.

SIR,—I had prepared a continuation of my paper on printing for the May meeting of the Manchester Photographic Society, but as the whole of the evening was taken up with matter which was entitled to precedence, I had not the opportunity of reading it. It has been determined to continue the meetings of the Society throughout the year, and I propose to resume the subject next month. I will at once, however, reply to those matters which I appear to have clothed in some ambiguity; but I desire, in the first place, to get rid of any credit to which I may have appeared to lay claim, but which belongs to others. I was aware that MM. Davanne and Girard had made known the results of experiments in photographic printing previously to those now in course of publication, but I had an impression that the inquiry had reference to the composition of the photographic image; at any rate, I had no recollection that they were conducted upon the comparative system that I adopted. I cannot now refer to the articles, but you are no doubt correct; and I at once retract that part of my paper bearing upon this subject.

It appears to me that it is not a matter of any importance whether I used paper or glass negatives; as requiring less trouble, I adopted the former plan, the strips of paper being fastened at each end upon the glass of the printing frame.

The sensitiveness I spoke of was that which enables prepared papers to receive impressions quickly, and had not reference to the ultimate darkening—that part of the subject was reserved; but, as the end in view is to obtain brilliancy and depth of tone, it was in part answered by the second division of the subject.

In reference to a supposed discrepancy between the results of my experiments and those of MM. Davanne and Girard, you will observe that my experiments showed a decrease in sensitiveness, due to the presence of nitric acid, but only in a slight degree; and in that principle we therefore agree. The greater effect, which appears to have been observed by others, may, as you observe, be due to the presence of albumen in the one case and its absence in the other.—I am, yours, &c.,

Manchester, May 8, 1860. WM. TUDOR MABLEY.

[We feel obliged to Mr. Mabley for this communication. We had not the slightest intention of imputing to him any unfounded claim to credit: our remarks were dictated by our estimation of his labours, and we felt convinced that our directing his attention to a simple fact that he had accidentally overlooked would be correctly interpreted by him.

The other points noticed we regard as more interesting than the writer appears to do.—ED.]

CATECHISING.

To the EDITOR.

SIR,—I shall feel much obliged by your answering the undermentioned questions:—

1st. If I am allowed to take photographs of the pictures in the Kensington Museum?

2nd. How long my developing solution will keep good after being mixed?

3rd. Which is the best way to take portraits in a room (it being more convenient than out of doors, as my dark room is at the top of the house)?

4th. What is the best material for a focussing cloth?

5th. Shall I be able to dry the prepared plates, 6×5 (in the Fothergill process) in an oak box 24 in. by 13 in., instead of a cupboard or in the dark room, it being more convenient?

6th. Is the crystal medium detrimental to the nitrate bath?

And, lastly, having purchased a good set of apparatus, I should like to know which process is best to commence with?

Being sorry for troubling you with so many questions at one time, and thanking you for past favours, I am, yours, &c.,

A PERSEVERING AMATEUR.

[1. We should scarcely think it probable.

2. It depends upon its nature, whether kept excluded from the air or not; and also much upon temperature. Use it till it ceases to act.

3. Place the sitter near the window (but not immediately in front of it), and have a white screen to reflect the light on the shaded side, which will otherwise appear offensively dark.

4. Black cotton velvet;—black twill answers very well.

5. Yes; but a tin box is better.

6. No; the crystal medium is simply talc.

7. Wet collodion, which must be mastered before any dry process is likely to give good results in the hands of a novice.—ED.]

DE OMNIBUS REBUS.

To the EDITOR.

SIR,—With your usual kindness please to oblige me with a reply to the following:—

1. How is gelatine (Dr. Norris's process) prepared, and does it require filtering before using?

2. An iodiser for Ramsden's (neg.) collodion, and quantity to collodion?

3. I have eight good negatives developed with iron. I tried to intensify one of them with pyrogallic acid three grains, glacial acetic acid fifteen minims, four ounces water, adding three drops of silver bath to the ounce: the picture is so weak that it will not print at all. Can I intensify them? If so, will you give a formula?

4. I filter my bath every day: on account of a black deposit always in the bath, the plates sensitised in it are covered with it. Do I lose silver by filtering so often?

5. What is the consequence of common tap water for the silver bath? I use a gutta percha bath. As I cannot procure distilled water, does it matter if I boil rain water in an iron tea kettle or saucepan, and filter before using it?

6. How is the honey made for your dry process, and what developer is used? also does the plate require much more exposure than wet plates? will the plates do for lantern slides? are they exposed and developed in the same way as you recommend to J. Cunningham in the Journal for May 1st? and in what number of your Journal shall I find an account of your honey process?

I hope I am not employing too much of your valuable time.

I am, yours, &c.

May 4th, 1860. JOSEPH DAY.

[1. Dissolve eighty grains of transparent gelatine in eighteen ounces of distilled water, to which add two ounces of absolute alcohol. Place the mixture in a bottle in a saucepan of boiling water, and apply the gelatine when warm. Filtration is unnecessary.

2. Most makers sell with their collodion an iodiser which they consider best suited for it. Unless the formula by which a given negative collodion is prepared, or at any rate its characteristics, be known, it is not so easy to say what iodiser would be *best* suited for it. The usual proportion is one of iodiser to three of collodion. Try the following:—

Alcohol	1 ounce.
Iodide of potassium	12 grains.
Iodide of cadmium	8 grains.

3. Your *negatives* cannot be "good" if they are "so weak that they will not print at all." You probably mean *positives*. It is not *always* possible to intensify positives into negatives that will give good prints; experience alone will guide you as to what kind of pictures are adapted for the intensifying process. Proceed thus:—Add a few drops of tincture of iodine to water, until a deep sherry colour is produced; pour this over the plate, and the image will soon become converted into one of iodide of silver, of a light straw colour: wash, and while still wet pour on a weak solution of nitrate of silver (two or three grains to the ounce), *in the daylight;* then in your dark room use your pyrogallic developer.

4. By repeatedly using the same filter, the loss of silver is very immaterial. From what you state your bath solution must be very much out of order.

5. As common tap water is very variable as to its mineral constituents, it should never be employed for the nitrate bath. Distilled water can generally be obtained in country towns, though it is not always to be depended on as *chemically pure;* but as you say you cannot procure it, collect rain in *a perfectly clean* glazed earthen vessel, boil it in a clean tinned vessel, and when cold filter it. This would be better than employing spring or river water, which contains salts that form precipitates with nitrate of silver. *Some* waters, however, produce so slight a deposit on the addition of nitrate of silver, that *on emergency* they might be employed after the following treatment:—Boil, cool, and filter as above; suspend crystals of nitrate of silver, tied up in a piece of muslin, at the surface of the water; stir—a greater or less precipitate will take place; as soon as fresh deposits cease to be formed, remove the remaining undissolved crystals; allow the liquid to stand at rest for some hours; decant the supernatant liquid, or filter. The water is then ready for use. With many waters this would prove rather an extravagant operation.

6. See Vol. II. for 1858, page 89, of this Journal, for the description of our honey process, and your queries pertaining thereto. Any dry plate, exposed under a faint negative, would probably afford views suitable for the magic lantern.—Ed.]

WET OR DRY?

To the Editor.

Sir,—1. Which is best suited for an amateur (both as to convenience and results)—viz., the *wet* or the *dry* process?

2. If the *dry* process should be adopted, which particular system would you recommend as most satisfactory and convenient—viz., the Taupenot, the Fothergill, &c.?

3. Which is most advisable to take—*stereoscopic* or larger views?

4. Will the ordinary portrait lens do for stereoscopic pictures?

I am yours, &c. S. S. L.

[1. Amateurs should always commence by perfecting themselves in the wet process before attempting to succeed with any of the dry methods.

2. The Fothergill process for facility—the Taupenot process if you wish to keep a stock of plates indefinitely.

3. It depends entirely upon your own requirements—stereoscopic to commence with.

4. *A quarter-plate* portrait combination, with a small stop placed between the back and front lenses, is well adapted for taking stereoscopic pictures; but a stereoscopic view lens is better suited for taking stereographs when both very distant and near objects are to be included in the view.—Ed.]

DEVELOPING SOLUTIONS.

To the Editor.

Sir,—After having often, as an amateur, made preparations in photography for a little exercise therein, I have frequently (and how many amateurs have been similarly situated), through business engagements or disappointment in visits from friends or the weather, to throw away my preparations for developing, from their not keeping sufficiently long to be ready when the opportunity for their use did arise.

With a view to aid the keeping of the developing solutions, it has occurred to me that if in each case the chemical which would itself deteriorate, and those in connection with it, were kept in a separate state in solution, to be mixed when about to be used, some loss of chemicals and vexation of temper might be avoided.

I make use of Mr. Hardwich's developer for my negatives; and having the impression that deterioration takes place sooner from the union of the acetate of soda and acetic acid with the other chemicals, I intend preparing the solutions in two separate equal quantities, keeping the acetate of soda and acetic acid with half the quantity of water in one bottle, and the protosulphate of iron in a state of solution with the other half of the water in another bottle.

For the positive developer I use the formula of MM. Davanne and Jouet, and intend keeping the iron and alcohol in solution with one half of the water in one bottle, and the acetic and sulphuric acids in the remaining half of the water in another bottle.

Then for a developing glass I make use of a test tube (according to the size of the plate), and graduate the same by a slip of paper gummed on outside and varnished over, and then whilst the plate is taking its dip, or after exposure, prepare the developing agent by pouring into the tube equal quantities of the two solutions.

Should it be requisite, in order to keep the solution, to apportion the chemicals into three or more separate bottles, then the test tube must be similarly divided.

Perhaps some of your chemical photographic readers will aid the amateurs with their views and advice on the subject, and save them from the labour and expense of *experiments in the dark*.—I am, yours, &c.

London, May 3rd, 1860. J. P. H.

P.S.—I trust the gentlemen whose aid is invoked will give me credit for a little more generous motive in attempting to cling to the skirts of their garments than that which actuated the monkey in obtaining the chesnuts from the fire.

[By the course of proceeding proposed you will not add to the stability of your iron solutions, though you may save some of the acetic acid and alcohol occasionally. You will find a better plan to be in weighing out convenient quantities of the iron salt for use, wrapping each quantity in separate papers, and keeping the same in a wide-mouthed stoppered bottle. When about to use a paper-full, have a small Wedgwood mortar in which you can readily triturate the crystals, and the solution will not occupy above a few minutes; or you can keep the iron ready powdered in your paper, if the bottle be closely stoppered.—Ed.]

ECONOMISING OLD BATHS.

To the Editor.

Sir,—I have a very acid bath, made for Sisson's waxed-paper process, as follows:—

Nitrate of silver	30 grains,
Lemon juice	8 drops,
Acetic acid	½ drachm,
Distilled water	1 ounce,
Iodide of potassium	½ grain,

which I wish to convert into a negative bath, *if possible*. Will you kindly say if this can be done, and how?—I am, yours, &c., D.

[We do not think it feasible to attempt to convert the above bath into a solution for negative collodion work. You may, however, succeed in using it for the paper printing process, if you first evaporate nearly to dryness over hot water to expel the greater part of the acetic acid. Then re-dissolve in exactly half the originalquantity of water, and add first five or six grains of citric acid to the pint, and then the same number of drops of ammonia. Citrate of silver will thus be precipitated, and will carry down the whole of the iodide of silver with it. Filter through blotting-paper, and satisfy yourself by using test paper that the bath still retains a slightly acid reaction.—Ed.]

ANSWERS TO CORRESPONDENTS.

Thankful.—We are very glad you have got over your troubles.

Samuel.—We shall be happy to give our opinion. You may send it if you please.

Something New.—Not in your communication; the idea is "as old as the hills."

S. Jones.—The subject you mention was embodied by Mr. Rejlander, of Wolverhampton.

C. F. (Lincoln).—We cannot perceive in what way your suggestion would be beneficial.

Sarah.—Touch the stain with tincture of iodine, then use cyanide of potassium, and yon will succeed.

R. Allen (Dublin).—See Mr. Dawson's paper in our last, and our leader in this number; you will then have the facts and opinions founded thereon.

Capt. A. N. Scott.—We have forwarded a letter and package, as desired, by mail, on the 4th instant.

James Allen.—We know of no work on the subject in the English language except "Hardwich's Manual."

Viator.—We are now "building" a new camera, constructed especially for rigidity, lightness, and simplicity; when finished, we may describe it.

Optico.—We believe that the compound photographic lens was first *made* by Mons. C. Chevalier, at the time Professor Petzval was *calculating* what its formulæ should be.

J. D. V.—If a subscriber, you can scarcely have been a *reader* of this Journal to ask for information which has been so recently given. Consult Mr. Wall's articles on colouring, and you will find all you wish to know.

A. B.—For replies to your several questions relative to Mr. Barnes's dry processes, we must refer you to a pamphlet published by him on the subject. We are not quite clear as to what his recommendations really are. We believe the pamphlet is to be procured of Messrs. Knight and Son, Foster Lane, Cheapside, London.

A Young Photographer.—Develop with—

Protosulphate of iron	15 grains.
Nitrate of potash	10 ,,
Distilled water	7 drachms.
Alcohol	1 drachm.
Nitric acid	1 drop.

Constant Reader.—Your signature is evidently a misnomer, or you would not inquire where to find information published in the 15th March number for the present year. We are always ready to afford information, but we do not carry an index in our head; and we do not perceive that there is any more trouble for you to look back a few numbers than to write, and virtually ask us to do so for you. Please have a little consideration.

S. F.—We never ridiculed the pictures produced by the panoramic lens, we simply corrected the false statements put forth relative to the *lens*, viz., as to its alleged freedom from causing distortion of the image, perfection of sharpness, &c. Be so good as to refer to our article again. We cannot join you in rejoicing at its shortcomings: we should have been delighted had it been a real advantage. It is, in our opinion, a *clever* failure, as already stated.

Received.—Israel Holdsworth, J. B. Hockin, Horne & Thornthwaite, J. Tyler, Aliquis, and C. D. Will all have attention in due course.

⁂ A large number of articles in type are unavoidably postponed.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

All Advertisements *and* Letters *on the* Business *of this* Journal *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 119, Vol. VII.—JUNE 1, 1860.

We would not pay so ill a compliment to our readers as to suppose their devotion to our art capable of being influenced by any such consideration as that of Court patronage; but assuredly they cannot feel otherwise than gratified to learn that Her Majesty and her Royal Consort, who have upon very many occasions publicly expressed, both by word and deed, their more than common interest in the advance of photography, not only continue to manifest proofs of their appreciation of its productions, but to show also that the same increases. Nor is this interest confined to the two most exalted members of the royal household, many, if not most, of the younger branches of Her Majesty's family partaking in the predilection.

Our readers will probably have observed an announcement in the daily papers that, on the 17th ult., Mr. Mayall, of Regent Street, was honoured by a command from Buckingham Palace to attend for the purpose of taking some photographs. Having had occasion to pay Mr. Mayall a visit on the following day, he favoured us with a private view of the negatives taken (upwards of half a hundred in number), as well as a few proofs from them, in an unfinished condition. We need scarcely state that the series is a highly interesting one, embracing as it does the representations of so many illustrious personages; and we can also affirm that the photographer has not only been a very successful operator upon the occasion, but that his artistic skill has been called fully into play, as evinced by the easy and graceful attitudes of his sitters, which add an additional charm to the productions, and testify that the "sittings" have been submitted to *con amore* in every instance.

A few weeks ago, by the courtesy of Messrs. Murray and Heath, we had an opportunity of inspecting the photographic outfit, just then completed by that firm, for H.R.H. Prince Alfred, which was intended to accompany him on his maritime expeditions. The whole of the paraphernalia were arranged in the most systematic manner in several cases, but in such a manner that whatever operation may be in contemplation, all the requisites for that operation in particular are readily separable from those that are not wanted; while the packing is so managed that no time is lost either in the operation of unpacking or of putting away again. This is a very great convenience, though one in which only the favoured few can indulge, in consequence of the additional expense involved from the necessity of having some duplicates amongst the chemicals and apparatus, as well as from the increased bulk.

Amongst the apparatus we would particularly notice a new stereoscopic camera, which is very compact and handy, the lenses, dark slides for a dozen dry plates, focussing screen, &c., all being included within the camera, which, when closed, forms a rectangular box, with lock and key, without any projection whatever. As this is a matter that will interest photographers generally, we will endeavour to describe it concisely.

When placed on the tripod for use, and unlocked, the back of the instrument opens like an old-fashioned pianoforte, so that the back and half of the top lie flat upon the remaining part of the top. The front also opens upwards, being hinged to the top, and when down, acts as a cap or shutter to both lenses at once. By the addition of an india-rubber band attached to a couple of pins, the same is applicable as a contrivance for giving a very short exposure.

A species of open box or deep tray, containing the double and single slides and focussing glass, is lifted out of the space uncovered by opening the back part previously adverted to, the tray being capable of suspension beneath the camera, not loosely, but by means of a tongue and groove of thin metal, so that any desired slide is immediately at hand, in a convenient position. Within the front, which is hinged at top, and at about one inch distant from it, is a second front in which the lenses are inserted; and attached to its opposite side is the working body of the camera, on the bellows principle, which closes up, when not in use, into the space not uncovered either at back or front, and when in operation is simply drawn back, and adjusted for focussing, into the space previously occupied by the tray of slides. It is not quite so light in weight as some we have seen, but is ingeniously constructed and pleasant to use. Amongst the accessory apparatus we must not omit to mention an improved form of pneumatic plate-holder, which is highly effective. We are surprised that any photographer should dispense with the use of such a simple luxury as a good plate-holder,—a luxury which not only conduces to the personal comfort of the operator, but also offers additional security against accidental stains on the plate and injury to the film.

We find from a recent number of a foreign contemporary that the experiments of Mr. C. J. Busk, detailed at page 98 of the current volume of this Journal, have attracted some attention in France, and with the singular pertinacity for which our continental brethren are noted, the phenomena are at once referred to the myth that was designated the "new action of light." It should be borne in mind that it was expressly stated at the time of the supposed discovery that paper "impregnated" with light parted with it if kept in darkness, unless in some hermetically-sealed receptacle; that, however, is a trifle not to be regarded for a moment by our contemporary, and we find the "absorbed light" theory applied to Mr. Busk's experiments in spite of the following passage which we quote verbatim, viz.:—

> "It is *not at all* necessary to expose the engravings or writings or other designs to sun or daylight before placing the prepared papers in contact with them. *A design that has not seen light for years can be taken equally well, and in as short a time.*"

Comment on the above would be simply loss of time.

In our impression of the 1st proximo our friend Mr. Hannaford, in his "Photographic Gossip"—in which, by the way, we regarded him as throwing stones right and left—while his hand was in, cast one at the practice of printing a proof from several negatives, combining portions from each. Had no one else done so we should not have considered it necessary to remark upon the subject; but in the present number we publish a letter (purporting to come from "Mrs. Spriggins," a lady who favoured us with some observations on the use of calomel upon a previous occasion), in which the same "air, with variations," is performed as that executed by Mr. Hannaford. Now we should

much like to know why any odium is sought to be attached to the practice in question? It appears to us perfectly legitimate; for observe there is no question of deception except an admitted and agreeable one—in short, it appears to us just as reasonable to condemn such a piece of ingenuity as it would be to object to a novel because it should bear the semblance of truth. Moreover, we cannot perceive the exact point where the odium (if any there be) could be said to cease. Roger Fenton, Lake Price, Grundy, and a host of others are equally guilty with Rejlander and Robinson; for have they not composed *genre* pieces, *e.g.*, "Turkish Water Carriers," "Bayadères," &c., "Don Quixote," "Robinson Crusoe," &c., "Fishermen," "Turks," *et hoc genus omne?* In what consists the difference between composing a subject and taking it on one plate, and taking portions of the subject on separate plates, and combining them subsequently, except that the latter is the more troublesome method, and, we may add, produces better results?

A LATE case of poisoning by photographic chemicals recorded in our publication of the 1st May, and a knowledge of the occurrence of other somewhat similar cases, has induced one of the members of our editorial staff to draw up a "Table of Antidotes," which will be found in another place, as useful to meet any future emergency.

It is intended to reprint this important Table on cardboard, with convenience attached for hanging up, in order that it may find a permanent place in every photographer's studio and chemical laboratory. Subscribers, Agents, and Booksellers may apply for copies to the Publisher of this Journal.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 5.

It is now a prevalent opinion that almost any substance may be used as a preservative agent in the collodion dry process, provided it be of organic origin, and be nearly neutral to test-paper. That such an idea should be entertained is not at all surprising, when we consider the number of methods which have been published, and from the practice of all of which success more or less constant may be anticipated. Nevertheless, we do not share in the belief that the choice of a preservative substance is a matter of indifference; so far from this, we believe that each substance has its specific reactions, and that much is to be gained by observing them closely. Mr. Macnair has lately read a paper on a dry process in which the plates are preserved by infusion of malt. A discussion followed the paper, and the members appeared almost unanimous in praising the results which had up to that time been produced by the process advocated. We confess to having entertained, in the first instance, an unsatisfactory feeling with reference to the employment of a changeable liquid like "sweet wort" in photography; but, as a friend observed, if it makes good pictures, what matter? A simple preservative method, economical and quickly performed, is likely to be useful, even if the plates could only be guaranteed for one day.

Taking our friend's advice, we stifled our scruples, purchased the malt, and mashed it in due form. That part of the process is simplicity itself. It seems scarcely necessary to weigh the malt; but any convenient quantity may be put into the recipient vessel, and a mixture of two measures of boiling water with one measure of cold water poured upon it, until it is well covered. The temperature of this water, as it flows on to the malt, will be about 160° F., and it immediately falls 15°, so that the thermometer stands about 145°. Doubtless the observation made at the time the paper was read on the importance of observing the proper temperature was correct, for the higher the temperature the larger the proportion of sugar in the wort, whereas at a lower temperature the dextrine is increased in quantity. When the temperature is raised still higher, or nearly to the boiling point, the mixture becomes pasty, and the changes due to the action of the fermenting principle are interfered with.

Infusion of malt is a liquid prone to change. We observed that it ran through the filter, at first nearly colourless, but after standing for a few hours on the table became as dark as sherry wine. The reaction to test paper was acid; in fact rather more strongly acid than we anticipated. The next point to examine was the effect of nitrate of silver upon it; and here we may digress for a moment to observe on the importance of testing any new liquid proposed for employment as a preservative agent, with nitrate of silver, to ascertain whether it throws down an insoluble salt of silver. When Dr. Norris's process was first published we did not meet with that complete success in practising it which we expected; and it is more than probable that our partial failure was due to the presence of chloride of sodium in the gelatine, the effect of which appears to be to weaken the image at every part, unless nitrate of silver be left upon the film in quantity sufficient to convert the salt into chloride of silver. Since then we have invariably adopted the plan of examining the proposed preservative with nitrate of silver and nitric acid; and on doing so with the "sweet wort," a very considerable turbidity was produced. The precipitate darkened in the sun to a brick red colour, and was easily soluble in ammonia, but not soluble in dilute nitric acid. We shall probably not be far wrong in saying that this precipitate consisted principally of a nitrogenous organic substance coagulated by nitrate of silver, and combined with a little chloride and likewise a little phosphate of silver.

With the hope of separating vegetable albumen, or any body of analogous composition, we next added absolute alcohol to a portion of the liquid, the effect of which was to throw down some flaky curds. These collected were found to be perfectly soluble in cold water and to precipitate nitrate of silver white: the inorganic salts went down in combination with the curds, which was precisely what we anticipated. What then, it may be asked, was the curdy matter? Probably it was *diastase*, or diastase mixed with vegetable albumen. Diastase is an unstable nitrogenous principle, present in malt to the extent, as we read, of $\frac{1}{500}$ of its weight; and in the warm aqueous infusion of malt exist also dextrine and sugar, both of which are products of the fermenting action of the diastase upon the starch originally present in the grain. We have never attempted to prepare diastase, and therefore if we were to attempt to describe its properties we should merely quote from books. Another body, however, of an analogous character, viz., "emulsine," is more familiar to us, and of this we proceed to give a short description. If the rough cake of the almond from which the oil has been expressed, be macerated with water, two organic principles are present in the liquid, amygdaline and emulsine. Amygdaline is a complex body soluble in water, but nearly destitute of taste or smell; and emulsine is what we term "a nitrogenous ferment." The molecules of this emulsine in presence of water are in a constant state of change, and by contact with the amygdaline they propagate their motion to the particles of that body, and cause it to split up into oil of bitter almonds, prussic acid, grape sugar, and formic acid.

In order to separate emulsine from its solution in water, highly concentrated alcohol is added; this occasions a flocculent deposit, which is the substance in question combined with a trace of earthy phosphate; the reaction of emulsine to litmus paper is slightly acid. From this description we see that emulsine and diastase are bodies of a similar nature; for just as the former resolves amygdaline into prussic acid and oil of bitter almonds, &c., so does diastase convert starch into dextrine and sugar. When water is absent, however, these changes do not take place; and emulsine, properly dried, may be kept in a bottle for any length of time, retaining its fermenting properties without deterioration.

The diastase contained in one part of malt is sufficient to convert the whole of the starch present in four or five parts of barley into sugar, as distillers are well aware. Thus the addition of barley to the malt in this dry process, may be permitted without destroying its characteristic peculiarity. An infusion of barley alone, however, does not react in the same manner with tests as an infusion of malt; neither could we expect to find in it those products of the conversion of starch which we have before alluded to, since the diastase is not present in the simple grain, but is produced in the grain during the process of germination.

We agree with a speaker who took part in the discussion on Mr. Macnair's paper, that the photographic effect of an infusion of malt could not be imitated by dissolving a given quantity of dextrine and sugar in water (this we suppose him to have meant by saying that he had tried an artificial wort). No doubt the nitrogenous matter present exercises a very decided effect, for these plates appear to develop free from fogging, in the same manner that we find when *serum of milk* is employed. It was thought at first, in the early days of photography, that the sugar of milk was the most important constituent of serum of milk; but this was soon found to be a mistake. The process of coagulating milk by rennet always leaves behind a little caseine dissolved in the liquid, and a trace

of caseine is found to assist in keeping the shadows of the picture clean, and in giving intensity to the blacks. So in like manner we presume that the nitrogenous bodies which precipitate nitrate of silver are useful in the infusion of malt, and that if they were entirely removed there would be a marked difference in the length of time during which the developer would remain clear upon the film. The developer, in fact, would turn muddy rapidly if no nitrogenous bodies were present, and the use of sulphate of iron would be liable to cause stains. Gum arabic we find to be a good preservative, but it does not confer the same property of resisting fogging as the infusion of malt.

In conclusion, we would advise the readers of this Journal to give the malt process a fair trial, and not to suppose for a moment that its publication furnishes an additional proof "that anything will do for a preservative." There are principles present in the sweet wort which are calculated to produce a very decided action in a dry process, and this observation will apply to either of the theories which have been advanced as to the conditions most proper for a dry collodion process.

ON THE APPLICATION OF PHOTOGRAPHY TO SCIENTIFIC PURSUITS.

By the Rev. F. F. Statham, B.A., F.G.S.

[Read at a meeting of the South London Photographic Society, May 17, 1860.]

The rapidity of execution and the accuracy of detail which characterise impressions of objects taken by the aid of photography, might seem to point out this art as one calculated to be of the utmost service to philosophers of all denominations in carrying out their experiments or in recording the results of their researches. But it is only by slow degrees, and as chance has suggested the adaptation of the photographic art to the advancement of various branches of science, that the importance of their correlation has been recognised, or the aid which photography is so capable of rendering been duly appreciated. The object of the present paper is not so much to chronicle the services which have already earned for photography a just title to be regarded as the "*handmaid of the sciences*," as by a brief survey of some of the benefits hitherto conferred to awaken public attention to the wide field of usefulness opened up by the discovery of this invaluable agent, and to suggest one or two additional spheres in which possibly the use of the camera may be hereafter rendered available. To give a just and accurate idea of *all* that photography has done for science would be to write anew the whole history of the art, and for this I have neither the time at my command or the requisite ability to grapple adequately with the task; but I have thought that a few *plain observations* from one warmly devoted to the interests of photography, though not even pretending to a practical acquaintance with the manipulatory branches, might call attention to the subject, and induce other labourers much more competent than myself to work out this scheme in a way which its importance deserves.

And, first of all, for the aid which photography has rendered to *chemical science*. It is true that photography is the child of chemistry; and we might perhaps more justly inquire what have been the services bestowed upon the photographic art by the agency of chemistry, than put the question of the benefits conferred in the opposite way. But I am prepared to maintain that, if a child once, photography has been a grateful child; and now that she has arrived at a state of maturity, she is repaying the advantages received in her condition of pupilage with a most bountiful interest. The practice of photography has so popularised the chemical art as to have called into existence a new generation of chemical students. It has infused a wonderful zeal into the study of this fascinating science, and has caused thousands to read the works of our most established practical or theoretical chemists who would never but for their love of the photographic art have consulted their pages. Add to this, that by necessitating a vast increase in the number of chemicals, it has originated a laboratory of its own; it has called into existence several totally new combinations of matter; and has wonderfully cheapened the cost of production of many of the most useful chemicals and drugs. Depending as it does for success so much upon neatness and skilfulness of operation, photography has gradually taught the young chemist qualities all-essential to the attainment of perfection in his favourite pursuit—*patience*, which will not be defeated by the failure of several experiments; the most scrupulous *cleanliness* in preparing and manipulating his apparatus; *self-reliance*, when by perseverance and industry he has once thoroughly mastered the processes of his art; and a *spirit of inquiry and adventure* which will prompt him to seek out new modifications of matter, or to note with a philosophic eye any unexpected or not easily explainable appearances which may present themselves during the prosecution of his experiments. I apprehend that chemistry, as a science, is only just beginning to reap the fruits which it may hereafter anticipate from the wide diffusion of a taste for photography among the choicest intellects of our land. Just as the alchemists of old, while spending their lives among crucibles and alembics and furnaces in the pursuit of a totally different object, still fell occasionally upon the discovery of some new compound which, after experience, proved to be of the most vital consequence to the advancement of chemical science, so I conceive it to be impossible that so many new labourers can be imported into the wide field of photographic experiment without occasionally picking up, in like manner, some jewel of philosophic worth which may hereafter open new sources of discovery to the chemists of future generations, or establish still more firmly the value and importance of the existing body of chemical truth. Who can deny the probability that we may even now be nurturing some embryo Davy or Liebig among our young and ardent photographers, when he considers how intimate is the connexion between the two classes of truth which are the mutual objects of pursuit of the chemist and the photographer, how each depends on the other for information and aid, and how both are fired by the same glowing ambition to make some new discovery which may be useful to mankind or serviceable to the cause of philosophic progress generally?

I pass on, however, to another branch of science which has derived no inconsiderable aid from the appliances of the photographic art. I mean *geology*. There is perhaps no science which is more indebted to the arts of accurate delineation than the science of geology. To be able to give a just idea to another of any peculiar physical feature—say, for instance, of a landslip, or a section of a coast, or the crater of a volcano, or the aspect of a mountain range—how thoroughly inadequate would all mere verbal description be! We feel at once that a few rude outlines with a pencil, or a roughly-coloured draught taken on the spot, would convey a much more correct impression of such an object or scene than whole pages of printed matter, or oral explanations however lengthy and diffuse. And hence all our standard works on geology are most profusely illustrated, and the amount of artistic skill which is to be witnessed in some of the more costly of them is of itself a source of great attraction. Now, I am not going so far as to assert that, under all circumstances, a photographic view of any scene of geologic interest would possess indubitable advantages over the sketch made by hand and coloured according to the tints observable in the natural landscape. Geologists are the anatomists of nature. They are not blind, it is true, to the grandeur and sublimity of its scenery, but as a rule it does not accord with their especial object to spend much time in the mere act of admiration. They generally want to get at the origin of physical appearances, and hence they are continually on the search for sections of the earth's crust which may reveal the superposition or the relative connexion of beds, or for sea-coast views, or railway cuttings where the internal economy rather than the beauty of the outward surface may be revealed. But still there are dozens of cases in which accuracy of detail is of the utmost consequence to the geologist in order that he may preserve the memory himself or convey correctly to others the results of his discoveries in the dark bowels of the earth; and where on a large scale any striking natural phenomena are to be delineated, it is obvious that the camera must be of the utmost value, if it be only to furnish the outlines of the sketch to be filled up subsequently by separate visits to the individual parts, or to serve as an *aide-mémoire* from which to draw with the graver or pencil an enlarged copy. In many instances, as in the delineation of fossils, or the transcribing of scenes of geologic interest, which would occupy hours and hours of hard labour in mere hand drawing, photography may be rendered most highly instrumental to the cause of geologic science. As examples I place upon the table stereographs of some tertiary fossils, recently found in the tunnelling for the great high level sewer at Dulwich, and views taken in the Scilly Islands a few summers ago of disintegrated granite masses, rock basins, and other scenes possessing an interest to the geologic student. My belief is that a series of well-executed photographs of all the characteristic fossils in our national museum would be of the utmost use in an educational point of view; and that the illustration of works on geology by means of photographic agency would be a vast improvement upon the system now so generally in vogue, where the cost of production renders first-rate illustrations all but impossible except in works produced and sold at a very high price.

(To be continued.)

A TABLE OF ANTIDOTES

TO THE

POISONOUS BODIES USED IN PHOTOGRAPHY,

(DRAWN UP FROM THE MOST RECENT MEDICAL AUTHORITIES,)

BY

SAMUEL HIGHLEY, F.G.S., F.C.S., &c.

LATE LECTURER ON MEDICAL MINERALOGY AT THE SAINT GEORGE'S SCHOOL OF MEDICINE, GROSVENOR PLACE, LONDON.

"PREVENTION IS BETTER THAN CURE."

ALTHOUGH the list of deadly poisons employed in photography make a formidable array, serious consequences through the practice of the art need not be anticipated if due and proper precautions be exercised by its votaries. All chemicals should be kept in a box or cupboard under lock and key, and every bottle should have its contents distinctly labelled. Chemical preparations, solutions, &c., should never be left about the domestic apartments, or on the floor or other places within the reach of children or animals. Jugs, basins, cups, or other utensils in domestic use, should not be employed for photographic purposes, but special vessels be kept apart for laboratory work. Servants and children should be forbidden ever to enter the sanctum of the developing-room or laboratory, or to touch anything contained therein. During the preparation of gun cotton care should be taken not to inhale the fumes. In the event of a bottle of a concentrated acid or ether breaking, the room should be abandoned, and the doors and windows put open till the fumes are dissipated. Chalk should be thrown upon an acid to absorb and neutralise it.

HOW TO ACT IN A CASE OF POISONING.

Send a messenger without a moment's loss of time for the nearest medical man. If the nature of the poison be known, write the name on paper and send it by the messenger. If there be no immediate evidence of the nature of the poison taken, the breath and the containing vessel should be smelt for any characteristic odour. A small lump of whiting or chalk should be dropped on one part of the containing vessel: if effervescence ensues the poison is an acid. A drop or two of vinegar should also be placed on another part of the vessel: if effervescence ensues the poison is an alkaline carbonate. The nature and colour of any spots about the mouth, throat, neck, or hands should be observed. In the absence of any of these signs, the early symptoms should be closely watched, and compared with those given in this Table. In drawing up this Table, all medical terms have been avoided, and the remedies recommended are those usually to be found at hand in the commonest household. In the event of the patient being placed in safety before the arrival of a surgeon, it must be borne in mind that medical supervision is necessary to anticipate any after symptoms that may result.

POISON.	SYMPTOMS.	TREATMENT.
SULPHURIC ACID OR OIL OF VITRIOL. Sp. gr. 1·800—1·845.	Immediate. Violent burning pain from the throat to the stomach and bowels, escape of gaseous and frothy matter, retching and vomiting of a bloody coffee-coloured fluid with shreds of tough mucus, which reddens litmus paper, and effervesces with chalk, whiting, or carbonate of soda. The lips, mouth, and tongue excoriated, shrivelled white, after a time turning grey or brown; the mouth becomes filled with a ropy and sticky accumulation; speaking, swallowing, and breathing very difficult; face then becomes blueish or livid; hiccup; motions, if any, more or less bloody or charred; constant but ineffectual attempts to pass urine; great tenderness of the abdomen increased by any movement; excessive thirst; pain increased by drink; pulse irregular; the skin cold and mottled; clammy sweats; great exhaustion; intellectual faculties clear until the last; convulsions; death in from eighteen to twenty-four hours after the poison has been taken. Death may result from strangulation caused by the swollen and inflamed state of the organs around the entrance to the throat. EXTERNAL INDICATIONS: Brown spots on the skin of the lips, neck, &c.; yellow, red, or brown spots on the clothes.	As the action of corrosive acids on the membranes of the throat is instantaneous, it has always to be feared that the power of swallowing may cease sooner or later. No time should therefore be lost in neutralising the poison that may have reached the stomach, by administering carbonate of magnesia, or solution of carbonate of soda mixed in water, milk, or barley water, a glassful every two minutes; in the absence of these, soap, powdered whiting, or chalk, mixed in water, may be substituted. It may be mentioned that simply milk and gruel given in large quantities has in certain cases arrested the corrosive effects. If strangulation threatens, the surgical operation of tracheometry may alone save life.
THE DILUTE ACID. Sp. gr. 1·420—1·103, &c.	Symptoms less severe and slower in making their appearance, according to the amount of dilution, and their partaking more of the character of an irritant than a corrosive poison.	
NITRIC ACID OR AQUA FORTIS.	Similar to the above, but frequently of a more acute nature; the lining membrane of the mouth and throat becomes after a time of a *citron yellow* colour; teeth white, and the enamel more or less attacked; vomited matter contains *yellow* flakes; body extremely cold; frequent shiverings and rigidity; swallowing causes severe pain; obstinate constipation; stupor; death. ⁂ *Should the patient partially recover,* AFTER CONSEQUENCES *have to be feared.*	
HYDROCHLORIC ACID, OR MURIATIC ACID, OR SPIRIT OF SALT.	Very similar to the above; acrid pungent vapours escape from the mouth in the early stages; the throat is the chief seat of pain; incessant vomiting.	
GLACIAL ACETIC ACID.	Corrosive action on the membranes of mouth, throat, and stomach; pain in the stomach; convulsions; death.	No antidote known, the immediate mischief being on the organ of the throat.
CYANIDE OF POTASSIUM. NOTE!!! ($2\frac{1}{2}$ grains of the pure salt = 1 grain of anhydrous prussic acid, or 15 minims of the acid of the London Pharmacopœia.)	Poisoning by this very dangerous compound of PRUSSIC ACID may arise not merely from it being swallowed in a solid or liquid form, but also by it being absorbed into the body on coming in contact with an abrasion of the skin or a cut. The vapour that arises from this substance is that of PRUSSIC ACID. The symptoms appear and run through their course with extreme rapidity; bitter cold taste, sometimes odour of bitter almonds; constriction and heat in the throat; insensibility; spasmodic respiration; the eyes fixed, pupils dilated and glistening; convulsions; paroxysms of long-continued spasm in the muscles of the jaw and body; sometimes resembling the characteristics of poisoning by strychnia; death. When taken in a concentrated form, its corrosive action may be sufficient to produce death by strangulation.	Bottles containing this body or its solution should be kept closed. When used as a fixing agent the room in which it is employed should be *well ventilated.* From the rapidity with which the symptoms present themselves, there is rarely ever time to employ antidotes. 1. Let the patient inhale the vapour of ammonia, sal volatile, &c. 2. Cold water should immediately be poured from some height in a stream on the naked head, neck, and spine. 3. A weak solution of PROTOSULPHATE OF IRON would decompose the poison, and convert it into Prussian blue. As this is a salt usually to be found in the stock of a photographer, it should be resorted to without a moment's delay. 4. Stimulants should if possible be got into the stomach.

ANTIDOTES TO POISONS USED IN PHOTOGRAPHY.

POISON.	SYMPTOMS.	TREATMENT.
BICHLORIDE OF MERCURY OR CORROSIVE SUBLIMATE.	Generally immediate; *metallic coppery* taste; suffocating sensation and burning heat in the throat, extending downwards; pain in the stomach increased by pressure; nausea; vomiting of stringy *white* mucus, streaked with blood; profuse purging; motions of a *mucous-like* nature, streaked with blood; face, lips, mouth, &c., sometimes swollen and stained white; the tongue white and shrivelled; pulse small, quick, irregular, almost imperceptible as the symptoms progress; skin cold and clammy; breathing difficult; sometimes suppression of urine; cramps; fainting; convulsions; death within twenty-four or thirty-six hours. *** *Salivation as an after symptom has to be anticipated.*	If vomiting does not exist, it must be produced by giving every few minutes a tumbler of warm water in which two teaspoonfuls of mustard have been stirred; then administer white of egg beaten up with water, frequently and in large quantity, to counteract (by decomposition) the effect of the poison. Should eggs not be at hand, flour mixed into a cream with water or milk may be substituted.
NITRATE OF SILVER OR LUNAR CAUSTIC.	Immediate; metallic taste, generally, those of other corrosive poisons; the *whitish* flaky matter vomited darkens on exposure to light. EXTERNAL INDICATIONS: The characteristic brownish black stains of this salt on the skin.	Dissolve a table-spoonful of common salt in a pint of water, administer a wine-glassful every two or three minutes to convert the poison into the inert chloride of silver; then give mucilaginous drinks, and follow up with purgatives.
CHLORIDE OF GOLD.	Acts locally like Nitrate of Silver. No fatal cases yet on record.	No antidote recommended.
AMMONIA AS VAPOUR OR IN SOLUTION.	Immediate; producing a feeling of suffocation, with great heat in the throat, which continues for a long time; inflammation of the throat and lungs may very probably follow; sometimes croup, hence fatal consequences. — If strong, like other corrosive poisons; taste urinous; smell of breath ammoniacal; after a short time the voice becomes reduced to a whisper, with other indications of great debility; vomiting of a large quantity of stringy salivary fluid, streaked with blood; bloody purging. Death may result from the immediate consequences, or from resulting inflammation of the breathing organs.	Immediate remedies:—A draught of cold milk; and same as for Vapour of Nitro Sulphuric Acid. — Vinegar and water, or milk with barley water may be given, if the power of swallowing should not have been destroyed. Prompt medical aid.
MURIATE OF AMMONIA OR SAL AMMONIAC.	Excessive vomiting, convulsions, and general stiffness of the muscles; great pain in the bowels; early alteration of features; death.	No antidote known; vomiting to be assisted by large draughts of warm sugared water, or if not successful, to be induced by tickling the back of the gullet with a feather or the finger. The after nervous and inflammatory symptoms must be treated by anodynes, anti-spasmodics, &c., under proper medical guidance.
POTASH AND SODA, CAUSTIC OR CARBONATED.	During the act of swallowing, an acrid, caustic taste; if taken in a concentrated form the membranes are softened and corroded; sensation of burning heat in the throat, extending downwards to the pit of the stomach; *if* vomiting occurs, portions of the lining membrane may present themselves, and streaks of dark brown coloured blood; the vomit effervesces with vinegar or other acid, if the carbonates have been taken; the skin cold and clammy; purging; pain in the stomach; pulse quick and feeble; after a short time the lips, tongue, and throat become soft, red, and swollen; convulsions; death.	Give vinegar and water, or lemon or orange juice freely, to neutralise the alkali, or give oil in large doses for the purpose of converting the alkali into soap, and to induce vomiting. Afterwards give milk, gruel, or barley water to dilute any alkaline matter in the stomach or bowels.
NITRATE OF POTASH, OR NITRE, OR SALTPETRE.	Nausea; painful vomiting; purgings; convulsions; faintness; pulse weak; breathing laborious; limbs cold; tearing pains in the stomach and bowels; a kind of intoxication; speedy death.	Give an emetic of two teaspoonfuls of mustard, dissolved in a tumbler of warm water. Afterwards large draughts of new milk with egg beaten up in it, or linseed tea.
BICHROMATE OF POTASH.	Pain; vomiting; dilated and fixed pupils; cramps in the legs; and insensibility.	An emetic of mustard in warm water, and afterwards the administration of whiting or powdered chalk, mixed up to a cream with water.
CHLORIDE OF BARIUM.	Nausea; vomiting of watery mucus; twitchings of the muscles of the face; convulsive motions of the hands and feet; distressing pains in the bowels; hiccup; violent convulsions; death generally within a very short period after the poison has been taken.	A weak solution of Epsom salts should be given plentifully to produce vomiting, and also to neutralise the poison by converting it into an insoluble sulphate.
SULPHATE OF IRON.	In very large doses may produce serious and even fatal effects.	An emetic of mustard in warm water, frequently administered.
TARTARIC ACID.	Has been known to act as an irritant poison when taken to the extent of one ounce in water. Immediate; violent burning sensation in the throat and stomach; continued vomiting; death within nine days.	Whiting or powdered chalk mixed to a cream with water should be freely and quickly administered. Warm water may *afterwards* be given to assist the efforts to vomit.
THE FUMES OF NITRO-SULPHURIC ACID.	The fumes that arise in the preparation of gun cotton if inhaled produce violent irritation and inflammation in the breathing organs; in one case on record to an extent that proved fatal.	Prompt medical aid; in the meantime inhalation of steam through a cone of paper placed tightly over a basin containing water just off the boil; and the application over the external surface of the throat and upper part of the chest of thin mustard paste, spread in muslin or a thin handkerchief. The irritation of the throat will also be alleviated by *frequently sipping* the following:—Grate six large lumps of sugar on a fresh rough rinded lemon, so as to extract *the oil* of the lemon; dissolve the sugar in a tumbler of water; add ten drops of *dilute* nitric acid; stir; after a yellow scum has formed strain through muslin, and it is ready for use.
BROMINE.	In the liquid form that of a corrosive poison; in the vapour form state that of an irritant, affecting the breathing organs.	Same as for fumes of Nitro-Sulphuric Acid.
FLUORIC ACID.	The same as Bromine.	
VAPOUR OF ETHER OR CHLOROFORM.	Produces lethargy and loss of sensation; the breathing becomes slow, deep, and noisy; the skin pale and cold; the face livid, and the lips dark blue; the eyes glassy, the pupils fixed and dilated, but sensitive to light; the muscles flabby and relaxed; when the pulse slackens, the temperature of the body rapidly falls, and there is frothing at the mouth immediate fatal consequences are to be anticipated. Where disease of the brain or heart exists death may occur very suddenly.	The face and neck should be exposed to a free current of air, and cold water dashed upon the skin. In an early stage, hot bottles to the feet, and brandy and water or other stimulants given internally, may be of service, but in an advanced stage prove inert. The main chance is by keeping up respiration by artificial means, which is thus performed:—One person must press steadily downwards with both hands the breast bone towards the back, whilst another with hands outspread at the same moment presses the surface of the belly upwards, towards the direction of the lungs; this presses the bowels against the cavity that contains the lungs, and thus expels *the poisoned air*; then let both persons at the same moment steadily release the pressure; a fresh supply of air will rush in to the lungs. Repeat this continuously at the rate at which a healthy person breathes.
PURE ALCOHOL.	Insensibility; breath smells of spirit; breathing loud and difficult; face swollen, and of a bluish red colour, with apoplexy or paralysis of one side. If the pupils of the eyes are dilated and fixed, recovery rarely takes place.	An emetic of mustard, or better, half-drachm or quarter of a teaspoonful of sulphate of zinc in a wine glass of warm water, and repeated in a quarter of an hour. Cold cloths and air to the head, warm bottles to the feet, with friction of the legs; medical aid, as bleeding may save life.

NEGATIVE VARNISH.

We received, some time since, from Mr. King, of Bath, a sample of varnish for negatives on glass, with a request that we would try the same and report upon it. It is only recently that we have found opportunity to make use of it, but it is somewhat difficult to come to any definite conclusion with regard to the value of such a material until after some considerable lapse of time, so that the effects of heat and cold, friction, pressure, &c., may become apparent: all we are able at present therefore to state is, that this varnish flows readily, has a considerable amount of "body," and hardens sufficiently without being "tacky" on the one hand or brittle on the other (that is during our short experience). Personally, we prefer a varnish that does not require the plate to be heated, as in performing the operation of coating it with varnish, under such circumstances, there are the two evils very troublesome to avoid, namely, "chilling" and consequent semi-opacity if the temperature be too low, and "ridges" if it be too high, especially in parts only of the plate.

We think it right, however, to observe that for professionals and others who require to take off many impressions from any one negative, it is hardly safe to employ any varnish that will work without heat, as otherwise, with the exception of that made of amber in chloroform, which is generally deficient in body, we have never met with one that hardens sufficiently to bear the requisite amount of comparatively rough usage to which a plate constantly in the pressure frame is naturally subjected. Indeed, we have upon more occasions than one seen the greater part of the film ripped off the plate on attempting to remove the printing paper from a negative which was supposed to be *protected* by varnish; the accident having in each case occurred when the frame had been exposed to the direct rays of the sun, and the resinous matter had thereby become softened—the varnish having also been applied without heat.

We think the varnish before us promises well for stability, and that it is certainly as good at least as most other kinds in the market.

ON FIXING POSITIVE PROOFS.

By MM. Davanne and Girard.

(Continued from page 132.)

IV. ON THE ACTION EXERCISED BY THE PROOF ON THE FIXING SOLUTION.

This part of our inquiry, the chief object of which is to ascertain the causes that bring about alterations in the baths, seem, at the first glance, to present serious difficulties; but the researches given above greatly simplify the phenomena we are about to study.

Having entirely abandoned cyanide of potassium, there now only remains to be examined—with reference to the alterations in the baths—ammonia and hyposulphite of soda. Now, the first of these presents no difficulty; as for the second, the facts previously ascertained render the inquiry easy.

First, as to ammonia. This re-agent shows no chemical decomposition, even after it has been used to fix a large number of proofs: a simple solution of salts of silver in ammonia has taken place,—salts of silver which the bath retains when it ceases to be in contact with the proofs. But this solution cannot be indefinite, it has its limits. Commercial solution of ammonia dissolves about nine and a-half drachms of chloride of silver to the quart; but the quantity of chloride dissolved must, of course, depend entirely on the strength of the solution, upon its richness in alkali. Therefore when the ammonia solution is saturated with chloride it is no longer safe to use it; for if a proof is immersed in it when so saturated, the *nitrate* of silver will be dissolved, but the *chloride* will not, therefore the fixing will be incomplete. Again, if the bath be not exactly saturated, is yet nearly so, it may become so even while the proof is in it, in consequence of the evaporation of the ammonia, and, consequently, incapable of dissolving the chloride. This salt will, therefore, be deposited upon the proof, and also in the body of the paper: subsequent washings will not remove it, and when the proof is exposed to the light, it will blacken all over. Thus it is that ammonia, besides the objection to its pungent odour, and the action it exercises upon the sizing of the paper, is also objectionable on other grounds. Ammoniacal baths become *old* as well as those of hyposulphite: they are, it is true, free from the objection of sulphurisation, but are open to that of depositing chloride of silver upon the whites of the proofs.

It is possible, however, to avoid these inconveniences by determining, on the one hand, the exact quantities of nitrate and chloride of silver solutions, ammonia, of given strength, will dissolve: and on the other, by never leaving a proof long enough in the bath for evaporation to produce a deposit of chloride upon it. Thus, with ammonia as with hyposulphite of soda, we must previously ascertain to what extent a fixing bath can be employed, or, in other words, how many proofs it is capable of fixing.

With regard to hyposulphite of soda, the influence the proofs exercise upon it is easily ascertained. Whether we put into it nitrate or chloride of silver, the action is always the same: the double hyposulphite of soda and silver is formed, which is dissolved in excess of hyposulphite.

$$(Ag\,O,\ S^2\,O^2)\quad (Na\,O,\ S^2\,O^2)\,2$$

The saturating point varies with the strength of the hypo. bath, and can be readily ascertained; but it is very quickly reached in all cases. It is upon this point, solely, that the alteration in the fixing bath depends. For until it is reached, the bath will be unchangeable. It will keep, as experience has proved to us, for many months; but immediately it becomes saturated (with the double salt) it must be considered as old. It will still fix proofs, it is true, but they will inevitably change: it deposits sulphide of silver either on the proof or upon the bottom of the dish containing it, and must, therefore, be entirely rejected. This deposit is accelerated by the action of light, as experiment has proved; for upon taking two portions of the same bath, slightly supersaturated with the double salt, and placing the one in a dark place, and the other exposed to light, the latter altered much more rapidly than the former. Exposing a bath in a wide shallow dish, acts in the same manner; and we incur further risk of alteration in the baths by employing the ordinary photographic dishes.

When a solution of hyposulphite of soda has arrived at this state of continuous decomposition, it should not be filtered, but thrown away; for after filtration the decomposition continues as before, and sulphide of silver is deposited anew. By adding fresh crystals of hypo. to the bath we can, it is true, communicate to it a greater capacity for saturation. In this case, however, the hyposulphite does not dissolve the sulphide of silver, as some writers erroneously assert, but it becomes capable of dissolving a larger quantity of the double salt, and, consequently, of fixing more proofs.

But we do not recommend this practice, for it involves uncertainty. It is better to operate systematically, taking a solution of hyposulphite of soda of certain strength, and fix in it a given number of proofs, determined by experience, according to the strength of the bath; and such a number, moreover, that the bath must be considered as useless, *even before* it has reached the point at which it becomes saturated with the double salt of silver and soda, the point at which it must be considered as *old*, and when it will, inevitably, alter the proof. It is the determination of this point that will next engage our attention.

ON THE SOLAR SPECTRUM IN ITS RELATION TO PHOTOGRAPHY.

[Read at a meeting of the Blackheath Photographic Society, May 21, 1860.]

By T. R. Wheeler.

With the double view of occupying a portion of this evening, when nothing of more importance presented itself, and offering a short *resumé* to such members as have not had an opportunity of reading the very interesting report of Professor Roscoe, of the experiments made by him and M. Bunsen on the relative actinic power of light in various portions of the world, presented to the Royal Society, I have taken the solar spectrum for a test; and if I do not pretend to bring forward anything original on the subject, I trust that I shall succeed in arresting your attention while I place in correlative order some of the phenomena of that most important imponderable agent—light. We call it an imponderable agent, and so it is, for it exerts an influence in common with heat and electricity without adding to the weight or bulk of the substance acted upon; and we judge of its nature and amount by the *force* which it is capable of exerting, rather than by its tangible presence. The question, therefore, "What is light?" is one more readily asked than answered; and I shall not occupy time in discussing either the corpuscular or undulatory theory, or speak further during this short treatise of many of the phenomena of light, which are so far foreign to my present object, viz., reflection, refraction, polarity, epipolic dispersion.

> "From matter streaming, it makes matter bright;
> Matter arrests it on its onward flight;
> And so, I fancy, 'twill but have its day,
> And when that matter endeth, fade away."—*Faust.*

The investigation of the imponderable agents is attended with considerable difficulty, it being often hard to separate abstract from concrete, force from matter. If the speculations of MM.

Grove and Seguin be correct, there are only two things in nature, matter and motion—the former an "entity," the latter a "state."

The facts associated with the action of the imponderable agents come under that class called in natural philosophy "ultimate"—that is, which resist analysis, and are rather subjects for speculation than perfect comprehension, whose *effects* only we observe, and are but rarely able to refer to a *proximate* origin, while their *primary* causes will probably for ever remain with their great Originator.

In nature, however, analogy seems t obe a leading principle, nothing existing as it were isolated, and no abrupt transition being found to exist. On this account Grove has framed his theory of a "homogenesis or correlation of physic a lforce."

In this sense we conceive light, heat, and electricity to be cognate powers, one being convertible into the other by any circumstance which is capable of changing their *states*. But this change always takes place in definite proportions, and the quantity of one force expended is in direct relation to the quantity of the force generated.

A ray of light impinging upon a daguerreotype plate forming part of a galvanic circuit to which a galvanometer is affixed, sensibly affects it, and at the same time occasions a change of temperature indicated by a thermometer. The change which light causes upon any sensitive surface is believed to be in its molecular arrangement.

Hence it appears to me that a close analogy exists between the molecular action of the light and what is called "catalytic action" in chemistry, the latter being an impulse communicated by the molecules of a body in motion to those of a body in a state of rest, inducing a change in the latter without the motive body itself undergoing change. A familiar instance is known in fermentation; the presence of spongy platinum causes the chemical combination of hydrogen and oxygen gases with explosion; and, not to multiply examples, several instances of a similar nature are known to chemists.

The allotropic condition of certain chemical substances occasioned by heat, and which can only be explained by the supposition of an alteration in their molecular states, is another striking point of analogy between light and heat. Electricity being sometimes an effect, and sometimes a cause of both.

Having premised this, I proceed to the consideration of the proper matter of my discourse.

It is familiar to knowledge that several portions of the prismatic spectrum, however produced, possess different physical characters, or, to speak more plainly, exert different physical actions; and it is equally well known that the red, the least refrangible, the most slowly vibrating rays, are those which contain, so to speak, the heat principle, or which, exerting a distinct influence upon thermometric variations, modify our climate, and are the proximate causes affecting the fall of rain and the current of winds, while the most refrangible and rapidly vibrating rays, those near the violet end of the spectrum, are chiefly concerned in chemical agency, and though, not in truth, the most highly illuminating, have, nevertheless, the most intimate relation with the photographer, inasmuch as by their influence those changes are effected on which his art depends.

The importance of the subject will be readily conceded; so great an interest has been attached to it by philosophers that a serious question has arisen among them whether the chemical rays were not a fourth imponderable agent, and the heat ray a fifth. A considerable portion of the *Philosophical Magazine* for the years 1843-4 will be found to be devoted to this discussion; and Professor Draper, of New York, designated the chemical ray "tithonicity," and our own countryman, R. Hunt, "energia"—the latter a purely abstract, the former a purely fanciful term, neither of which have, I believe, been permanently received by the scientific world, or the category of imponderable agents extended to meet these theories.

To measure the amount and variations of these particular rays has always been a great desideratum with the philosophers, and *a fortiori* with the photographer, and hence from time to time various actinometers have been proposed; and if, as Dr. Roscoe has well observed, any instrument could be invented to be worked on the principle which renders the thermometer so valuable, and which has been termed the first law of Planiotte, viz., that the expansion of the volume of mercury is equal with equal increments of heat, then a perfect actinometer would be presented to the public. To find such an arrangement, and to apply it to investigating the amount of chemical light in the ray in different parts of the world, was the object which MM. Bunsen and Roscoe proposed to themselves; and I shall confine myself for the present to a description taken from Dr. Roscoe's report of the mode by which they carried it into effect.

I have before stated that various photometers had been proposed, the principle of which was somewhat similar; but the exposure of certain chemical compounds to the action of light are such that either a re-arrangement of their constituents should take place under its influence, or actual decomposition with the extrication of some gaseous product, the amount of which being calculated afforded an approximate conclusion as to the power exerted by the light. I shall first mention that of Sir John Herschel in 1840, or more properly, perhaps, that of Mr. Jordan, in 1839. These were simply sheets of photographic paper wound round a cylinder, inclosed in another cylinder, which was moved on its own axis at a definite rate by means of clock-work. The light being admitted through vertical slits in the outer cylinder, impinged upon the sensitive surface, and by adjusting the rapidity of its movements so as to keep the slit always opposite the sun, the paper recorded every variation in its light. It may not be superfluous to state that the arrangement did not differ materially from that at present in operation at the Royal Observatory for registering the diurnal variation in the magnet by artificial light, under the able superintendence of our friend the late president.

Mr. Hunt next produced an instrument which he termed an actinograph, of a somewhat more complicated nature, but upon the same principle. Professor Draper, of New York, has, perhaps, devoted more time and attention to the question than any other philosopher. Commencing with the action of light upon surfaces of the chloride and bromide of silver, he suggested an instrument to which he gave the name of a tithonometer, from "tithonicity," the title he invented for the chemical ray. This consisted of a mixture of hydrogen and chlorine in equal parts, which being exposed to light were known to combine to form hydrochloric acid with such energy as sometimes to cause explosion. Other actinometers have been proposed, but this presents the special interest of being the one chosen by MM. Bunsen and Roscoe, with some modifications which appear to be approved by Professor Draper for their extended experiments.

(To be continued.)

A FEW REMARKS ON AMATEUR PHOTOGRAPHY.

By F. Howard.

[Read at a Meeting of the South London Photographic Society, April 19, 1860.]

(Concluded from page 132.)

But to return. If the amateur is determined to produce pictures, not having the time for experiments but when a holiday can be got, let him ramble away with the camera. I know nothing more likely to conduce to health and the enjoyment of nature than outdoor photography—looking out for nature's most smiling features. It is astonishing how far you can walk, and what a weight you can carry, and how much more you see, when out with the camera than under ordinary circumstances. If, in addition, you bring home some good pictures, you will think it one of the best holidays you ever spent, and will wish for another. But you must not imagine from my enthusiastic picture that there are no such things as failures and misfortunes, which the amateur must expect to meet. I have myself walked about day after day, prepared and carried dozens and dozens of dry plates, with no results worth keeping, till almost disheartened; but I think I can say that success was much sweeter when, at last, I managed to obtain a tolerable picture. I will now offer a few remarks on what I consider the best method of practising photography by an amateur.

After well studying the art, having lessons from a proficient, and ascertaining the why and wherefore for using the various chemicals, solutions, &c., apparatus and chemicals should be purchased of good quality, to ensure subsequent success; and, though the results may soon begin to give satisfaction, I would advise a continued practice in copying prints, objects of still life, &c., as it is a very difficult thing to get a good negative, and likewise very difficult at first to distinguish a good one when you have got it. The same remarks apply to printing, which likewise requires great practice, otherwise, when you have got a good negative, you will not know what to do to get the best print from it. Portraiture, which amateurs are very fond of indulging in when commencing, I would recommend to be deferred for many reasons. In the first place, it is about the most difficult of all the photographic branches: it is that branch which is open to, and receives, the greatest amount of criticism. You have to deal with many more obstacles than in landscape photography, and it will tax your patience and ability to

the utmost: it is from this cause alone that so many have been induced to give up the prosecution of the art, they having commenced too early to portray their friends and acquaintances; and, perhaps, what may be called good-natured remarks of admiration at the first efforts do as much mischief as anything. As flattering likenesses are unknown in photography, the poor amateur gets flattered instead, hence a fruitful source of trouble: his eyes are shut to the faults and errors for correction; and, if he unfortunately has no acquaintance or friend, who is a photographer, to show him his faults and help him over these pitfalls, he will get into difficulties, and possibly give it up. He may attempt to take the portrait of a friend, and being satisfied with what he will very likely find out hereafter is a very bad negative or positive, may prevent a better representation being taken of him: the friend may die, or leave the country, and the unfortunate amateur finds himself in possession of a bad photograph as the sole representation of his friend, without the possibility of repairing his fault; therefore, what was intended to have been a great source of pleasure becomes one of pain. Again, the attempt to take a likeness by an amateur is generally attended, at the outset, with so many difficulties that success is very doubtful, unless he have a glass-house and plenty of time, which few amateurs possess. He will have to find out the best position, arrange his background, and if the operating-room is far from the yard or garden where he has placed his sitter, the necessary running backwards and forwards will not in any way compose his nerves or steady his hands; nothing, perhaps, has been used for a fortnight or so; there is apparatus to dust, solutions to mix, collodion to test as to exposure, glass to clean, measures and funnels to wash, and if anything goes wrong (and it is a wonder if it do not), he gets annoyed, and not having had experience enough to imagine where the fault can be, he gets perplexed, perhaps wonders if he ever shall succeed, and ultimately satisfies himself with a very indifferent production for want of a better. If you were to ask a professional to undertake the task, under these circumstances, he would hesitate a long time I am sure. All I can say to amateurs is, don't do it. If you feel yourself able to produce a good negative make a rule of getting ready some hours before: much waste of material and much annoyance will be spared you.

I would myself recommend amateurs, as a rule, to confine their attention to landscape and architectural photography, either stereoscopic or larger, as it pleases them; though I would recommend stereoscopic, as, in addition to the greater facilities with which the views can be taken, they are, as a rule, more attractive to friends, and, if desired, can be enlarged from at leisure for the portfolio. As to wet or dry processes, I will not enter into a controversy about their merits, either as to results or convenience: if wet, you must make up your mind to carry a great deal more baggage, and put up with some additional expense in the way of assistance when out; if dry, you must work well and perseveringly at home before you venture to go far, to ascertain the right exposure, and to learn how to treat your plates under development, as a failure is not to be replaced under the penalty of going over the same ground again. Gentlemen practising, or thinking about practising, the dry processes, would do well to see the results arrived at by Messrs. Bourne, Mudd, and others, at the Society's Exhibition this year. It has been said that a photographer should be able to produce pictures by any process; but to that idea I do not subscribe, as I think to command success, having satisfied yourself that the particular process you are about to follow will give good results, you should follow that process and no other: do not be led away by the promised results of others.

From what has come under my own observation the dry processes are much used by amateurs, as gentlemen may see by specimens which I submit for their inspection as amateur productions; and I do not wonder at it, as a process which admits of being followed at leisure, and is so readily available when an opportunity arrives, is essentially the amateur's boon—it is the greatest incentive to follow the pursuit. I for one think that there would not be one-half the amateur photographers if it were not for the dry processes. I doubt not but some manufacturers of photographic apparatus will bear me out in this assertion.

I cannot finish these remarks without drawing the attention of amateurs, who may regret the want of time, to how much may be done for about four months in the year in early morning; much time may be got for practising; and from May to August operations may well be commenced by five o'clock in the morning—indeed, in or near London, it is much the best time, as the atmosphere is then much clearer than in the middle of the day. Cleanliness is most important: using, as we do, vessels and apparatus at intervals, one is apt to forget what was last in them, and I would advise making sure by well washing before using. Never make shift with common in place of distilled water for developers, nor use stale solutions, &c.

This subject admits of a great deal being said upon it; and if a discussion may ensue, the offer of these few remarks will give me greater pleasure than I anticipated.

ON VARIOUS KINDS OF GLASS, WITH REFERENCE TO THEIR APPLICATION TO PHOTOGRAPHIC PURPOSES.

By J. A. Forrest.

(Concluded from page 113.)

By far the most important branch in glass making, in connection with photography, is that of sheet glass. It is blown into the form of elongated cylinders, which are split and unrolled into flat rectangular sheets, the rounded ends being previously cut off. Having already described the process of crown glass making in a technical manner, I will not task the general reader with any further description of a similar kind, but at once proceed to give the component parts of glass, and show their bearing in the uses of photography.

The ordinary sand used in glass making contains traces of iron, which gives a green tint to the glass. To correct this evil the manufacturer uses small portions of manganese and arsenic; but for photographic purposes, especially for roof glass, the introduction of these articles are ruinous—the former becoming, through exposure to the light, of a strong pink colour, and the latter a yellow, both thoroughly opposed to the transmission of actinic rays. A blue tint of a slight degree favours the transmission of the chemical ray, and, as far as my experience goes, a glass so prepared with cobalt is perfectly permanent. I judge from pieces that have been exposed for centuries in cathedral windows, and have always found the exposed and unexposed pieces to be exactly similar in tint. There is another advantage in the use of blue tinted glass: it allows the sitter to be posed in a strong light without his feeling the light irksome to his eyes.

The following is a selection of the mixtures of glass now in use:—

CROWN GLASS.

Silica (sand)	64·
Soda	22·
Lime	12·5
Manganese	1·5
	100

SHEET GLASS.

Silica (sand)	63·5
Soda	22·5
Lime	14·
	100

When sheet glass is made especially for patent plate the mixture is usually—

Silica (sand)	73·
Potash	6·6
Soda	10·
Lead Oxide	6·4
Lime	4·
	100

Sheet glass, manufactured for patent plate, is first reflattened, then obscured, and afterwards smoothed, preparatory to being placed upon the benches for the polishing of the same. The glass must lose its fire skin, and consequently becomes porous; hence it should be kept in a dry place, with white paper between each plate. Never use printed matter for this purpose, for the impression is almost certain to appear on developing the plate when sensitised and exposed. To clean glass of this kind, take a piece of fustian and nail it upon a flat piece of wood as tightly as possible, saturating its surface with rouge and water, and rubbing the glass upon the same, taking care to wash it thoroughly.

These observations hold good in reference also to purple plate and colourless patent plate, which undergo the same process. Too great care cannot be taken to see that it is perfectly dry after washing, otherwise the artificial lustre will be seriously injured. Purple sheet is made with manganese, and is used for glass positives, giving a backing of an agreeable tone without the use of black varnish. Some experience is required to know how to develop a picture upon this glass. It is much more extensively

used in the United States than in this country; and this is remarkable, seeing the facility and despatch that is gained by its use. Opal glass is admirably adapted for printing transparencies upon, and no doubt will be brought into great request by M. Joubert's burnt-in process.

ON THE MEASUREMENT OF THE CHEMICAL ACTION OF THE SOLAR RAYS.*

By Professor H. E. Roscoe.

(Concluded from page 97.)

The method by which the measurement of the chemical action of the solar rays is determined is, to allow a very small but known portion of direct solar light to fall upon the instrument through a little hole in a metal plate placed in the shutter that darkens the room. The sun's rays are reflected by a *heliostat*, the mirror of which moves with the sun, so that the reflected ray always remains the same. The sun's rays, thus reflected by the mirror, are allowed to fall upon the instrument, and combination of the gases takes place.

Some observations were made on the 15th Sept., 1858, during a cloudless sky, the direct sunlight being affected only by its passage through the atmosphere. They were begun at nine minutes past seven in the morning. When the sun's distance from the zenith was 76°30', the action observed in one minute was 1·52. From that time it kept on increasing, until at fourteen minutes past nine, the last minute of observation, in consequence of the appearance of clouds in the sky, the action observed was 18·51, thirteen times greater than at nine minutes past seven. The sun's zenith distance had become less, his height above the horizon was greater, and the chemical action of the solar rays had increased, which is to be entirely attributed to the fact, that the solar light in passing through the atmosphere is to a certain extent extinguished, absorbed, lost as light. Therefore the thicker the column of air through which the light has to pass, the greater the absorption or loss of light must be. When the sun is low in the heavens, the length of the column of air through which the rays have to pass is greater than when the sun is on the meridian. This, then, is the sole cause of the rise in the chemical action. The morning and evening shadows are not so intense as those of noon-day. We cannot put the instrument into the sun's light, for then it would explode; we must therefore calculate the ratio between the little hole in the shutter and full light.

When we know the amount of action the sun produces at a given height it is possible to calculate the action it would give at any other height, if we know the latitude of the place. The amount of chemical action effected at the earth's surface on a cloudless day by the direct solar rays depends solely upon the sun's zenith distance, and upon the thickness of the column of air through which the rays have to pass.

Now, if we know the law which regulates the absorption of the sun's rays in the atmosphere, we can calculate what the amount would be, supposing the sun's rays arrived at the earth perpendicularly through the air. We find that the loss is about two-thirds; we really receive only one-third. If the sun's rays were not weakened by their passage through the atmosphere they would produce an illumination represented by 318 degrees of light; or they would effect a combination, in one minute, on a surface upon which they fell perpendicularly, of a column of hydrochloric acid 35·3 metres in height. The sun's rays having passed perpendicularly through the atmosphere to the sea level, effect an action of only 14·4 light metres, or nearly two-thirds of their chemical activity is lost by dispersion and extinction in the atmosphere.

From these, and many other interesting results, we may calculate the amount of chemical action which the sun's direct rays produce at any place, when we know the latitude and the thickness of the air through which the sun's rays pass. The activity increases as we approach the equatorial regions. The mode of measurement described is not one that can be universally adopted. The instrument is too complicated for every day use. In the hands of an experienced person, this photometer is a valuable instrument; but it requires special treatment during at least a week before it is fit to be used, and even then a moment's inattention may spoil it; and when it is to be used in the morning, the instrument requires constant watching and attention during the whole of the previous night.

At present we know of no easy and, at the same time, accurate mode of measuring the action of light. Much time and labour have already been expended by the inventors of this apparatus in endeavouring to prepare an accurate instrument that shall be capable of being used with facility, and it is to be hoped that their efforts will be crowned with success.

* Condensed from a Lecture delivered at the Royal Institution, on the 2nd March.

Exhibition.

PHOTOGRAPHIC EXHIBITION AT SALFORD.

[FROM OUR SPECIAL CORRESPONDENT.]

We are glad to find here another instance of the gradual way in which our favourite science is taking its place among the arts called fine. The Committee of the Peel Park Museum, in making arrangements for their annual summer exhibition, to which Her Majesty is a contributor, determined to devote the wall space of one room to the display of photographs, the produce of local photographers—all pictures to be untouched. This is a move in the right direction, and an exposition is secured of pure photography, without instituting undue comparison with the works of continental or other distant artists, a comparison which, however, many of the works exhibited would well sustain. But the Committee have gone further and done still better than this, they have secured the willing services of the Manchester Society, whose exhibition committee have undertaken the superintendence of this part of the exhibition, and have discharged their duties in a way which we are sure will give general satisfaction.

The centre of a room in the new wing of the Museum is occupied by a bedstead of silver, of valuable but barbarous workmanship, which, from being the chattel of some eastern potentate, has become the property of Her Majesty, who lends it to this exhibition. Its cumbrous velvet canopy deprives us of some light, but not to any serious extent. There is also beneath its canopy the cradle made in 1814 for the expected deliverer of Israel, of whom the credulous followers of Mrs. Southcote were in eager expectation.

We feel ourselves in some difficulty in treating of this exhibition: the display is so uniformly good, so neatly arranged, and the subjects so varied, as to preclude our using almost any other than words of admiration.

There is as yet no catalogue printed, and we have taken the trouble to make one for ourselves; and when we find in it some thirteen pictures by Mr. Mudd, the same number each by Mr. Wardley, Mr. Mabley, and Mr. Higgins, and a dozen from Mr. Mann, the zealous Secretary of the Manchester Society; when we find Messrs. Sidebotham, Compton, and Thorpe sending more than a score, and mention that our friend Mr. Young has contributed a frame containing twenty exquisite stereoscopic subjects, we have almost said sufficient to convince our readers of the excellence of the exhibition, though some of them may think the number (about 200) rather small. Nevertheless we would wish to remark upon some of them.

Mr. Wardley's *West Door of Manchester Cathedral* is a fine bit of work, and his view of that smoky city from Blackfriars' Bridge positively recals many pleasant memories of more sunny climes.

Mr. Archer should confine himself to one branch to ensure success: he shows three pictures, each by a different process, of which the Fothergill *(Hopwood Mill)* is the best.

Mr. Petschler seems to be a persevering operator: his *Worsley Hall* deserves commendation; it is much superior to that by J. W. Thompson, who falls short in the arrangement of his subject and exposure of his plates.

Mr. Sidebotham sends some beautiful specimens: one would be surprised if it were otherwise. His *Wheat Field* and *Ancient Bridge at Strines* are highly suggestive pictures, and show careful development and printing.

Mr. Compton and Mr. Thorp seem to have been labouring at pretty nearly the same subjects, and *Kenilworth* is the best with both of them.

Mr. Mudd's pictures are all gems in their way. There is a capital print of his prize picture, *Coniston Falls* (the medal itself ought to be suspended from it); and, as a complete contrast, take his *Lincoln Cathedral from the West*, a perfect piece of architectural photography, not, we think, to be beaten by anything we have seen. Mr. Mudd's *Bridge at Yewdale*, and *Yard at Messrs. Rothwell's Works at Bolton*, and his *Old Mill at Dunham*, show how artistically very diverse themes may be treated by the same operator.

The Society's Secretary contributes some small but interesting pictures, collodio-albumen, as are all we have named. His *Shipping at Runcorn*, with pure untouched skies, are very neat, and he sends one copy of an engraving, *Crossing the Ford*, which is a capital one, and the only representative of the oxymel process.

Mr. Bennett Lowe sends two good Fothergill pictures, one of which is admired much—*A Farm in Shropshire*. The hard outlines of the distant hill is objectionable, but perhaps unavoidable.

Mr. Higgins has been very successful with *Fountains Abbey* and *Lincoln Cathedral*, and one of his pictures would be really to be coveted but for an over-exposure, which makes it more curious than correct. It represents a copse, with an old bridge, the distant foliage being singularly blanched.

A number of pictures shown by W. D. C., show a great variety of subjects, chiefly Scottish, but are all very indifferently printed.

Mr. Mabley of course is a large contributor, in both collodio-albumen and wet collodion. We must especially mention his diagram of machinery, drawn as well as photographed by himself: his *Glastonbury Abbey*, *Barrington Court*, and *Llandudno*, the one showing a general view of the town and bay. We fear, however, that Mr. Mabley has not quite done himself justice in his choice of prints: most likely the short time allowed prevented this.

Mr. Young should really try larger pictures now: his stereoscopics are complete, well chosen, neatly executed, and altogether desirable acquisitions to a dealer in such matters. He seems to have considerable rambling propensities, for he shows views of Chester, North Wales, Dovedale, Scotland, Yorkshire, and, nearer home, *Hoar Frost at Cheetham Hill*. We wonder if his fellow-worker, Mr. Parry, was with him much in these; if so, why he does not exhibit we cannot imagine, as anything from him must certainly be good.

We miss contributions from many others who we know produce good pictures in this branch, both on glass and paper, and we regret their shortcomings very much. The windows of this room would have afforded ample and fit space for the exhibition of transparencies.

I. Davies, of St. Ann's Square, sends some good pictures in collodio-albumen. We believe we must take *Rostherne Church* to be a type of his style, and it might certainly be improved on; accordingly in *Dead Game* and the *View in Yewdale* we trace a following of the master hand of Mr. Mudd.

One picture, *A View on the Irwell*, by A. F. Smith, makes us long for a sight of other productions by him.

Mr. Brothers is a large contributor, chiefly of portraits and copies of engravings. He has, however, a picture of *Manchester Exchange*, which is very good, and may go along with Mudd's *Royal Infirmary*. The lines in this plate will bear accurate testing for *correct drawing* we were going to say, but that can hardly be said, though it expresses what we mean. We recommend the use of paper more highly albumenised for untouched portraits than this gentleman uses; it throws up the half-tone much better. He has succeeded well with ivory miniatures, as two excellent specimens attest. His copies of engravings and pictures are generally good. He exhibits portraits in water colours and oil: these are on a screen in another room, not to infringe the rule so rigidly exacted as to the subjects being untouched.

The London School of Photography, who have a branch in Manchester, send eighteen small vignettes and portraits, which for cheap work are as good as any which have come under our notice.

There are no glass pictures or negatives in the exhibition.

We come now to notice the contributions of some members of the Chorlton Society. This society is but a young one, but some of its members are old amateurs: if they all produced pictures like those of *Agecroft Bridge*, by Mr. Hooper, by the turpentine waxed-paper process, we would not complain at all. Mr. Chadwick's copy of Sir T. Lauder's picture of *Christ Teaching Humility* is not badly executed as regards the negative, but we think a better print might have been shown. We cannot say much in favour of Messrs. Adin and Davies' (of Warrington) productions, under exposure marks the former, and very defective composition the latter, as well as very indifferent toning. Mr. Davies works with collodio-albumen. One of his pictures, being *a View of Great Ormshead*, should be called "Topsy Turvey;" for we are told, and it is really not a bad joke, that it puzzled all the Committee as to which was "this side up," and it was settled by finding in a corner some persons reclining; but the man who has framed the plate since (and the frames are nearly all provided by the Museum Committee) has actually placed it on its side, and the aforesaid persons may now be seen reposing comfortably (?) heads downwards,—at least it was so when we saw it. But we are sadly exceeding our present limits, and must wind up by saying that we are informed that the opening *soirée*, on the 23rd, given by the Mayor, was quite a success: we were not, however, honoured with an invitation, nor with tickets to the private view, which extended over the rest of the week, at which we are rather disappointed. No doubt during the current week, the date of the Manchester *ludi circenses*, which take place within rifle range of this exhibition, will be visited by thousands. Without wishing to disparage our national sports we cannot help saying they will here find a more rational, a more instructive exhibition, even if they confine themselves, as we are compelled to do, to this particular department; but we are sure they will not venture to gainsay our opinion on this subject when they ramble through the other galleries of the building where so many valuable specimens of paintings, of art and manufactures, modern and ancient, European and Asiatic, and such fine examples of natural history in its various branches, are deposited. Σ

Meetings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual monthly meeting of the above Society was held at the Lecture Hall, Walworth, on Friday, the 18th ult.,—W. Ackland, Esq., Vice-President, in the chair.

The minutes of the previous meeting having been read and confirmed, donations to the folio were acknowledged from Mr. Wall and Mr. Ackland, for which the usual votes of thanks were awarded.

Mr. Ackland, Mr. W. Clarke, and Mr. Hannaford, desired their names to be inserted in the list of members forming the Exchange Club.

The Rev. F. F. Statham, B.A., F.G.S., President, then read his promised paper *On the Application of Photography to Scientific Pursuits.* [See page 159.]

After the reading of the paper,

Mr. Wall said he had listened to their excellent President's very comprehensive paper with much pleasure, but really had no remarks to make about it. There was, it seemed to him, nothing to hang a doubt upon, nothing to deny, nothing to dispute, only something to admire. He had listened to it as he might have listened to some enthusiastic and eloquent friend praising the virtues and accomplishments of his mistress, with this exception, namely, that he did not feel the slightest throb of jealousy during the whole process.

Mr. Hannaford thought their President had so fully treated the subject that very little remained to be said. Some of the specimens brought down in illustration of the geological section of this paper forcibly recalled the characteristics of certain scenes in Devonshire and Cornwall, and reminded him also that there was evidence to prove that the rock basins alluded to were not all attributable to natural causes, but in at least many instances were, he thought, Druidical remains, formed upon the highest point of certain localities with a view to receiving the rain water used in some of their religious ceremonies. There was this difference between the natural and artificial basins to be observed, viz., that while the latter were provided with channels or lips, always occurring in certain positions, the former were not, which, if their formation was due to natural causes, would, he thought, be the case.

Mr. Leake, referring to the importance of photography to the geological student, said he thought a good photographer, acting under the personal superintendence of some able geologist, might do much to extend the great popularity of geology as a science.

Mr. Statham in reply, said he was conscious of not having done full justice to his very prolific subject, for to describe the possible, probable, and already adopted applications of photography to scientific pursuits, required more time than he was able to devote to them. The stereographs of rock basins which had called forth Mr. Hannaford's remarks were taken to illustrate a paper in which he intended to disprove the possibility of their artificial formation. Upon this subject, when microscopically examined, they gave much evidence. The lips or channels which Mr. Hannaford referred to were found in connexion with such basins as occupied a very exposed situation, and were formed by the mechanical action of water, influenced by wind and assisted by the loosened particles of the disentegrated granite. He had hoped that some member would have enlarged upon the subject of photography in connexion with astronomy—referred to the coming eclipse, &c.

The usual vote of thanks was enthusiastically awarded to Mr. Statham, whose kindly services and genial manners appear to have won him golden opinions from the members generally.

Mr. Ackland having vacated the chair (which was then occupied by the President), said he was desirous of calling the attention of members to a matter connected with the Fothergill process, which might possibly prove of some little importance. He had been much annoyed by getting certain particular stains on his developed plates, which always occurred near the end on which the plate stood to drain. Having ascertained that this did not arise from the draining itself, he next noticed that the water (six drachms for a stereo plate) became but slightly milky when he used *new* collodion, and very much so when he used *old*. This led him to the conclusion that the new collodion, forming the most compact film, retained the free nitrate of silver more pertinaceously than the old, and that, consequently, the same amount of washing more completely freed the latter from the silver than the former. Bearing in mind that a weak solution of albumen is not readily coagulated by nitrate of silver, he thought it possible that all the free silver in the compact (or new collodion) film was not converted into the albuminate, thus originating the stains in question, which stains he did not meet with when using the more porous collodion. Mr. Ackland then detailed some further experiments, tending to convince him more thoroughly of the accuracy of his con-

clusions; in the course of which he strongly recommended a strict habit of carefulness and cautious observation, by noting the temperature of the operating-room, chemicals, &c. To ensure a shorter exposure and yet avoid the species of stains which he had described and exhibited, he had made the following slight modifications in the Fothergill process with the most satisfactory result:—

Collodion—half new and half old—to be used within a week after the mixing.

Sensitise and wash as usual. Then pour on the albumen and immerse *before washing* in a solution of common salt. Lastly, wash thoroughly. The importance of decreasing the time of exposure without obtaining the stains which so annoyed most operators, and which, up to the present time, remained unexplained, would, he hoped, justify the time he had occupied in making this communication. In conclusion, he much regretted that Mr. Howard, in whose opinion he had much faith, as in that of a practical and thoroughly successful operator, was not present to aid the discussion.

The Secretary greatly regretted that this, their excellent Treasurer's first time of absence, was occasioned by ill health.

The President thought Mr. Ackland's remarks were of great practical value, and called upon the members to award the usual vote of thanks, which they did with much warmth.

Mr. Hannaford said the stains attributed to the albumen might arise from using it in a too dilute state. A large quantity of ammonia might naturally enough be supposed to throw down the nitrate of silver as the oxide, but in practice this was not found to be the case; and Mr. Howard, one of the most uniformly successful of operators in the Fothergill process, used a very large proportion of this ammonia. [Mr. Ackland had previously stated that he used ammonia in the preparation of his albumen.] The use of chloride of sodium would, of course, be advantageous in adding to the keeping properties of the plates. Acetate of soda would give greater intensity, and might be employed, with some sorts of collodion, with excellent effect.

The discussion was then continued by Messrs. T. Clarke, G. W. Simpson, Leake, jun., Ackland, and Hannaford; in the course of which the latter gentleman said the Fothergill process was, in his opinion, not adapted for large plates.

Mr. Ackland described some few experiments he had made with large plates, and thought this arose from manipulatory difficulties which were surmountable, and not to any defect inherent in the process. He thought at least a minute necessary to dilute the albumen.

Mr. Hannaford advised washing under the tap.

Mr. Ackland would not recommend a lengthened washing, which materially increased the time of exposure.

After some further discussion, Mr. Leake read the following—

PHOTOGRAPHIC JOTTINGS. No. 6.

I have this evening to call your attention to a modification of the tent I exhibited at an early meeting of the Society, and also to a travelling case, constructed to carry all the apparatus, &c., required for a day's outdoor photography.

The tent consists primarily of a shallow box or tray, about twelve inches wide, two deep, and twenty-two inches in length, the lid forming the top of the tent. Round three sides of these the covering of black and yellow calico is secured, the fourth being covered by a curtain of the same material, sufficiently large to wrap round the operator and exclude light. The top is supported by two light iron rods, which keep the covering in a state of tension, thus ensuring perfect rigidity. In front of the tent a portion of the black covering is removed, and yellow substituted, to admit sufficient light for convenient working. A gutta-percha tray, with a flexible tube attached, carries off the waste water, and the whole is supported by a tripod stand of a height to suit the operator. When not in use, the covering folds into the box, of the dimensions above given, which may be carried by the handle attached to its side. The weight is about four and a-half pounds.

The travelling case is constructed of mahogany, and contains spaces properly fitted for the camera, bath, chemicals, plates, and all the various paraphernalia requisite for a day's out-door photography. The size of this box is about eleven inches high, eleven wide, and six inches thick. I think this will be found to be a useful piece of apparatus, as the operator will be able, on looking over his box, to tell at a glance if anything is missing. Messrs. Squire and Co. have at my request undertaken the manufacture of this apparatus, and to them I must refer those gentlemen present who have been inquiring where it might be procured.

A vote of thanks was awarded to Mr. Leake.

The President thought Mr. Leake's apparatus very ingeniously contrived, and singularly portable.

A similar opinion was expressed by all the members present.

Mr. Ackland exhibited a camera (Powell's) with certain recent improvements and increased accommodation for the dark slides, which met with much approbation.

The President said, hearing that it was the wish of the Committee that their first anniversary meeting in June next should be of a more than usually pleasant and social character, he should be glad to meet the members at his own residence upon that occasion.

The Secretary warmly thanked their President for the kindly feelings expressed in his present very generous invitation, and in his past services, but could not consent to avail himself of an offer entailing upon that gentleman expenses which it would be scarcely fair to permit him to incur.

Mr. N. E. Fitch rose to support the Secretary, and to thank their respected President for his great kindness.

It was then arranged that at their next meeting the members be invited to a *soirée*, to be held at St. Peter's School Rooms, near the church gate of St. Peter's, Walworth.

NOTICE TO THE MEMBERS AND COMMITTEE.

Upon the occasion above referred to, refreshments of a simple description, music, stereoscopes, microscopes, &c., will be provided. Mr. T. Clarke has also promised to exhibit in the lanthorn a series of photographic slides, and it is hoped that various other objects of interest and curiosity will be exhibited by the members and their friends, all of whom are specially invited to attend upon this occasion. The annual report will be read a little before the usual hour of meeting, and the election of officers and new members duly proceeded with immediately afterwards. The Secretary has received the names and addresses of several gentlemen desirous of joining the Society, and will be glad to increase the list. All communications may be addressed to him at No. 90, Cannon Street West, City. The members of Committee will hold an additional meeting on the Wednesday previous to the usual evening appointed for committee meetings, and make the necessary arrangements, &c.

ALFRED H. WALL, *Hon. Sec.*

BLACKHEATH PHOTOGRAPHIC SOCIETY.

The twenty-fourth ordinary meeting of this Society was held on Monday, the 21st ult., at the Golf Club House, Blackheath Hill,—the President, Charles Heisch, F.C.S., in the chair.

The minutes of the last meeting having been read and confirmed, the President made known to members a plan which was being agitated for holding a *soirée* during the present season, jointly with other societies in the neighbourhood.

It was moved by Mr. South, and seconded by Mr. John Harding,—"That this Society join the Greenwich Natural History Society and the West Kent Microscopical Society in a *soirée*, to be held at some convenient time and place during the present season."

It was moved by Mr. Glaisher, seconded by Mr. Spurrell,—"That this Society bear one-third of the expense of such *soirée*."

"That the President, two Secretaries, and Messrs. H. Terrel and Wood, be appointed a committee to meet that of the other Societies."

It was then resolved unanimously,—"That a gold medal be offered to the Golf Club, as a recognition of their kindness to the Blackheath Photographic Society in allowing the meetings of the Society to be held at their rooms; such medal to be considered as a prize medal, to be held under regulations to be laid down by the Golf Club." The Secretary to procure patterns and estimates, to be placed before the Society at its next meeting.

The President then called upon Mr. T. R. Wheeler, who proceeded to read a paper *On the Solar Spectrum in its Relation to Photography*. [See page 162.]

At the conclusion of Mr. Wheeler's paper, the President described the mode in which paper was prepared for photometric purposes, explaining the difficulty which attended it, and the precaution necessary.

A vote of thanks was cordially tendered to Mr. Wheeler.

Mr. Melhuish then exhibited some photographs of Rome, also a particularly interesting series of stereoscopic Sicilian views, lately photographed by Mr. Napper.

The meeting was then adjourned.

The following, read at the April meeting, has been circulated amongst the members:—

THIRD ANNUAL REPORT OF THE COUNCIL.

The Council of the Blackheath Photographic Society, in presenting to its members their Third Annual Report, cannot but congratulate them upon its present position and future prospects.

Established three years ago by about seven members, the Society has now increased to forty-two; and the treasurer's account shows a balance of not less than £43 15s. 7d. in favour of the Society.

Its prosperous financial condition is to be attributed in no small degree to the courtesy of the Golf Club, at whose rooms the Society's meetings have been held during the past year. The Council beg to tender their best thanks to the officers of the Club for their continued kindness.

During the session 1859-60 the Society's meetings have been numerously attended, and the following list of papers read before it testifies to the zeal and energy of its members. The Council take the opportunity of here acknowledging the kindness of the press in all that relates to the publication of their transactions, referring especially to the *Photographic Journal*, The British Journal of Photography, the *Photographic News*, and the *South London Journal*.

PAPERS READ BEFORE THE SOCIETY UP TO THE PRESENT PERIOD OF THE SESSION.

"On the Application of Photography to Investigations in Terrestial Magnetism and Meteorology, as practised at the Royal Observatory, Greenwich." (Concluded.) By the President.

"A Paper on Van Monckhoven's Cellulose Process, as investigated and practised by T. R. Wheeler."

"A Paper upon Positive Printing." By A. J. Melhuish.

"On the Employment of the Salts of Magnesium as Iodisers." By Charles Heisch.

"The Pistolgraph and its Use." By T. Skaife.

"The Method employed at the Royal Observatory for registering by Photography the Diurnal Variations in the wet and dry bulb Thermometer." By the President.

"On the Reproduction of Engravings, Prints, Ordinary Writing, or Letter-Press on Prepared Papers by Contact in the Dark." By Chas. J. Busk.

A review of the subjects touched upon testifies that the appeal made to members by the Council in their last report has been well responded to; but they would earnestly reiterate that appeal for original matter to be brought forward at the Society's monthly meetings, feeling persuaded that their success will be promoted from this, rather than from any other source.

The Council cannot point to any very striking contributions to the practice of photography during the past year. The nature and composition of the photographic image—a question of high interest to the photographer—is still occupying the attention of chemists. The experiments recently made by Mr. J. Spiller, of the Royal Arsenal, Woolwich, published in the *Philosophical Magazine* for March, 1860, tend rather to confirm the conclusion of MM. Davanne and Girard that the image consists of a mixture of metallic silver with unchanged chloride, and are so far opposed to the views of Messrs. Maskalyne, Hardwick, Hadow, and Llewellyn.

The alkaline gold toning processes are still receiving considerable attention, each modification having its particular advocate. The method, generally, bids fair to be a great improvement upon the old process.

The prints exhibited by M. Joubert, said to be from ordinary negatives, with printer's ink, are superior to any ink pictures yet produced; but, as his process is still a secret, the Council can offer no opinion as to its practical application.

Cognate to the subject of photography are the experiments of MM. Bunsen and Roscoe, lately detailed before the Royal Society, which will be read with great interest by every photographer.

An attempt has likewise been made to employ cotton dissolvèd in oxide of cuprammonium instead of collodion, recommended by Van Monckhoven as immeasurably cheaper and, in some respects, more uniform in its composition than collodion. The process would appear to merit further trial.

Since the publication of the last report the Council have the pain of recording the decease of two of the Society's members—Mr. Hughes, of the Royal Hospital, Greenwich; and Mr. Howe, of Dartmouth Row—the latter a practical photographer. It may not be superfluous here to note the loss the scientific community has sustained in the death of Mr. Andrew Ross, the optician, of Featherstone Buildings.

The Council have considered it expedient, during the course of the present session, to present to members of the Society a print, from a negative kindly lent by Mr. Glaisher for publication; and it is their intention, as far as the funds of the Society will permit, to follow that issue by one or more during the ensuing year, as may be determined by a committee appointed by the Council for that purpose.

In conclusion, the Council congratulate the members upon the high perfection to which photography has arrived in its numerous practical applications, not less than upon the prosperity of the Society itself,—pressing upon them the necessity of research and original experiment, as the true means by which advancement is to be hoped for; and feeling satisfied that what is added to the general store of facts, not only promotes the character of the source from which it emanates, but becomes the property of mankind for ever.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

The monthly meeting of this Society was held on Tuesday evening, the 29th ult. Mr. Haines, one of the vice-presidents, occupied the chair.

Mr. Sutton, of Jersey, was to have been present for the purpose of reading a paper on *Panoramic Photography.* From some cause, however, he did not make his appearance. Much disappointment was expressed by the members at this, as no provision had been made for having another paper read; and the Secretary was requested to ascertain why the engagement had not been kept.

The only business transacted was the election of Mr. H. P. Robinson and Mr. Keene, of Leamington, as members of the Society.

Mr. Robinson, who was present, exhibited (in an unfinished state) one of the composition pictures for which he is becoming famous in the photographic world.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

SHADOWS.

(See Maxims 42, 43, 44, 37, 38, 54, 63.)

Now work upon the half shadows* with a *thin* mixture of Venetian red and Chinese white, your object being to destroy the coldness of the photographic hue and assist in converting it into a warm greyish tone.

A few delicate touches of pure vermillion (thinly applied) may be next used in the shadows, and a little madder carmine† may be combined with it for the more intense darks, over which may also be worked a mixture of madder carmine with Indian yellow and Indian red, until the blackness gives place to a warm transparent effect, which, if these colours be judiciously used, will soon be apparent. Still, remember what I have so constantly urged, viz., *don't hurry.* If any shadows require defining more strongly, use for the purpose madder-brown: those which are called "cast-shadows,"‡ and which will be found upon the shadow side or beneath projecting features or surfaces, will be sure to require strengthening in parts with this pigment.

THE EYE.

(See Maxim below 45.)

Put in the pupil of the eye with indigo, or indigo mixed with a little lake and sepia; the iris with cobalt, outlined with a little cobalt and indigo; touch in the reflected light with cobalt and Chinese white;§ strengthen the markings of the lower eyelid with Indian red or madder brown (the latter if the photograph be faintly printed); and touch in the lash with "warm sepia:" this latter colour may be also used for the eyebrows. The edge of the upper eyelid must be warmer and less dark where nearest the nose. Soften the edges of the shadows at the corners of the eye and under the lower eyelid by hatching and stippling upon them with cobalt and light red. Work into the socket of the eye a faint, delicate lilac tint with a little madder pink and cobalt. Take a little cobalt over the white portion of the eye, and work some of the same between its corner and the nose. Put a few touches of vermilion and madder pink into the corner of the eye nearest the nose.

THE CHEEK AND LIPS.

For the lips and cheek a colour is made by mixing vermilion and madder pink, using most of the one or the other pigment according to the requirement of your model. For the complexion you are now painting, or supposed to be painting, use rather more vermilion than pink. Hatch and stipple the colour into the cheek with patient care, and with faint and oft-repeated touches, preserving the purity of the colour, and avoiding every appearance of an artificial effect by softening and diffusing the pink into the greys around. This done, colour the lips with the same, using a little lake and vermilion for the upper or shadowed lip, softening the edge of the lower lip with great care, and preserving the high lights, half and reflected lights, toning down the colour as it recedes from the light, but at the same time securing a fresh, bright, moist appearance. Owing to the light's chemical "effect dejective" the lips are almost invariably too dark, and the high light too large, as I explained when speaking of the treatment to be adopted for polished bodies. For this reason rather more vermilion may be used for the lips than the cheek; and sometimes it will be necessary to prepare the lips for colouring, by working upon them with thin washes of Chinese white, slightly warmed with a little vermilion; upon which, before proceeding with the colour, it may be as well to use the burnisher, but do not do so until the colour is perfectly dry. If the white is put on too thick it will work up and spoil your colour. In applying the colour over the white use that recommended for the cheeks, and having less vermilion. The division of the lips and the darker touches may be given with a little lake and burnt sienna.

* The half shadows will be found between the lighter half-tones and the shadows, uniting harmoniously the first with the last.
† In the list of pigments given in a former chapter this colour was forgotten.
‡ Shadows which are cast by projecting surfaces.
§ Supposing the eye to be blue.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

G. P.—I am glad you find the papers so useful.—One of my most earnest and sincere friends and a very able teacher.—See report in the present number. Shall be glad to meet you.—The background contains too many straight lines. Beauty is the soul of art, and curved being always acknowledged to be more beautiful than either horizontal, perpendicular, or oblique lines, it follows that your picture lacks an element of success, when there is no reason in the world why it should do so. If straight lines are necessary, let them be soft and indefinite—not abrupt and hard. In arranging accessories acquire a custom of tracing an imaginary outline which shall bound and unite every object; and if this outline is a graceful one, and otherwise consistent with the rules of composition, you may be sure that its subtle influence will make itself felt even in the minds of those who are unable to detect its actual existence. Nothing is more essential to all who would produce pictures—whether by pencil, brush, or camera—than a knowledge of the laws governing artistic composition. See reply, in the last number, to "A. S." The case you describe is that of "a blind and rash barbarity, which rejects what is most beautiful, and seems with an audacious insolence to despise an art of which it is wholly ignorant."

A Brother in Arms.—Hope you pay more attention to your drill than you have done to my instructions. All I can say to you is—"Atten-sion!" "Right-about-Face!" "Quick-Mar-r-r-ch!" "Halt!" and being "as you were," *begin again,* but this time *at the beginning* you must stay longer in *my* crypt before you can claim your "first-class ticket" up stairs. I am afraid you are one of our self promoted comrades who, having passed one day in the crypt, one in the yard, and the third in the hall, applied for a corporal's chain and—*somehow*—got it. Those who enlist with the volunteer colourists don't "go-a-head" in that style.

A Lady.—The flesh is too chalky; the greys too uniformly cold, or too decidedly blue. The pinky colour in the cheek is too pure and peach-like in hue for the sallow complexion: it is unnatural and inharmonious—work a little venetian red and indian yellow over it. The greys, half-tones, shadows, &c., must all harmonise with the general appearance of the complexion, or the effect will be strikingly untruthful.

M. J.—See reply to "A Lady," and remember that the reflections should blend tenderly into the shadows, and, unless the object from which the light comes is visible to decide the colour, keep them warm.

An Artist whose Works have been Hung on the Line.—You might be a laundress whose "washing" was hung on the line, from the style in which you speak of art. If *I* thought photographic colouring that which you term it, I might adopt your advice; but the study of colour may be pursued for its own sweet sake with as much advantage to me in connection with photographic colouring, as painting and drawing (according to your own admission) have been to you. You may be very sincere in your remarks, and, believe me, I do not appreciate the motive which dictated them the less from being of an entirely opposite opinion.

Foreign Correspondence.

Paris, May 26, 1860.

For the worthy inauguration of this correspondence, in which it is my intention to sum up from fortnight to fortnight the most important facts connected with photography in France, I should have liked to have some capital discovery to announce—

some sure method, for instance, of obtaining unalterable pictures, or the fixation of the natural colours, or aught less wonderful even. But, alas! I have no such tidings to communicate. Spring has in vain lavished her longest days—the sun in vain has shed his brightest beams—our experimentalists, if not idle, are at least mute. Not the smallest secret leaks through the bolted doors of their laboratories. The Photographic Society itself, which had expected some interesting experiments for the monthly meeting of Friday (the 18th instant), was obliged, in the absence of those who had promised, to defer its hopes for another month. During the ten years that I have driven the critical pen, I have remarked at different periods such moments of pause; but I must add that they have nearly always been followed by important discoveries. And, besides, our seekers have already found enough to be entitled to occasional repose without hearing themselves accused of sluggishness. Well, then, there is nothing new in the form of process; but so far as production is concerned, the activity of the little photographic world, living in the midst of the great Parisian city, —a working tribe that nothing distracts or arrests,—*that* is anything but flagging. Our artists are profiting largely from the favour accorded to their works by the public; and they do right. Every day they offer to the eager but capricious crowd of amateurs numerous and attractive productions. At present there is not a printseller of any importance who does not exhibit in his windows from day to day a certain number of photographic pictures, to say nothing of the opticians, and of those shops where the stereoscope reigns absolute.

Shall I tell you what are the publications which more particularly attract the attention of the crowd, and which are to be met with everywhere? In the first place, I will mention the reproductions of paintings and drawings executed with so much industry and talent by your countryman, Mr. Bingham, who has, so to speak, monopolised this difficult application of photography. The list of them is long. First, there is a large portion of the pictures which figured in the last Exhibition; then the complete works of Meissonier, of Paul Delaroche—a real monument—and of Ary Scheffer, a religious *epopée*. Letter-press has been added to the last-mentioned work, which is the most important of the kind which photography has hitherto produced. Mr. Bingham has also reproduced a good number of paintings and designs by various authors, which appear every day in the windows of our publishers, attracting the passers-by, and holding them spellbound. I must also mention the splendid collection in which Messrs. Bisson Brothers have brought together the principal views of the glaciers of the chain of Mont Blanc. These pictures have a boldness and a beauty of execution which fully justify their success. Lastly, I will speak of the *Galerie des Célébrités Contemporaines*, an exhaustless series of card-portraits, invading even the stationers' shops, and thence inundating the *salons* and also the *boudoirs* of Paris and the provinces. What I am saying is not by way of criticism; I do but state a fact. These little portraits are in general very cleverly executed by some of our best *portraitistes;* only, what is to be regretted, and what offers a singular idea of our French public, is, that this collection, commencing with the Imperial family, and including our most eminent men in politics and in literature, in science and in art, finishes off with the erratic figure of Mademoiselle Rigolboche, one of the lowest actresses of one of the lowest theatres in Paris, whose sole title to renown is her impudent immodesty. I will add that this portrait is not the least sought after, and that it will certainly bring larger profits to the author and the publisher than will those of certain men who have spent their lives in the noblest labours of intelligence. *O, tempora! O, mores!* The vogue enjoyed here by card-portraits in general really passes belief. Several of our artists do nothing else, and their *ateliers* are besieged by the crowd. It is, in fact, quite a mania. At all the bookbinders and the stationers you see richly-bound albums, with clasps, which are specially destined to receive these portraits *à la mode.* The most graceful gift that can be offered to a lady at present is one of these volumes, in which she can bring together all her friends, allotting to them such and such a page, according to the place occupied by them in her heart. One fashionable lady, in my circle of acquaintance, received three of these albums within two days: it is true that she has many friends.

I cannot pass over in silence one very important fact, which will be of great advantage to photography. In all the *ateliers* which I have visited during the past fortnight, for the purpose of gathering information and news to communicate, I have found that the one theme of conversation and object of enthusiasm is Woodward's solar camera. The constant answer to all my questions was a lengthened eulogy of the apparatus and of the advantages possessed by it. In fact, after having seen what it produces, one is obliged to acknowledge that the results are wonderful. During ten years I have witnessed the attempts made to amplify the pictures by means of various instruments, but nothing hitherto obtained is comparable to what is offered by the new solar camera. The first picture which Mr. Bingham presented to the French Photographic Society, and which was the reproduction of a stereoscopic picture, was much admired; but since then much better and much larger ones have been produced. A few days ago I saw in the *studio* of Messrs. Mayer Brothers and Pierson, bust-portraits of the size of nature, and surpassing everything which photography has obtained up to the present time. My excellent and illustrious friend, M. Claudet, who was passing through Paris on that day, accompanied me in my visit, and, familiar as he has grown with the prodigies of our art, he was, like myself, wonder-struck.*

I saw M. Pierson operate in my presence—he made three pictures upon iodine paper from the same *cliché* (17 centimètres by 21): the first in thirteen seconds, the second in seven, and the third in two seconds. In the development we recognised that the first was over-exposed, the second was better, the third was perfect. Count Aguado has also obtained some very fine results upon salted paper, which is much slower; but another amateur, whose name is equally well-known in the photographic world, has gone farther. He has reproduced full-length card-portraits with an amplification which reaches the proportions of nature. These pictures are nearly six feet high. To attain this end he places on his screen three sheets of paper in juxta-position, and these, receiving at the same time the same impression, take in the subsequent baths exactly the same tint, and when well joined form but one and the same picture. In this manner full-length portraits of the natural size can be obtained, with the inconvenience of gigantic dishes and costly baths. For this kind of work amateurs and professional men have all adopted similar arrangements in their studios The apparatus is fitted, on the sunny side, to one of the walls of a dark room sufficiently large to admit of two or three persons moving about freely, and performing the various manipulations. An easel mounted on truckles supports the screen, and may be placed at the requisite distance from the apparatus by means of two wooden rails upon which it slides. To obtain a direct picture upon positive paper it is necessary to expose for nearly two days.

At the moment of closing this letter, I have received from M. Vernier, of Belfort, to whom we are already indebted for useful information, the communication of a process, which the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY may perhaps be able to turn to account. It is a method for harmonising over-exposed pictures, and consists in plunging them into a bath of cyanide of potassium composed as follows:—

Water	600 grammes.
White cyanide of potassium	1 gramme.
Concentrated liquid ammonia	6 grammes.

Notwithstanding the smallness of the quantity of cyanide, this bath is sufficiently active to harmonise the image in from four to eight minutes, according to the intensity of the positive; but its employment is still more advantageous for pictures taken upon *clichés* presenting a great opposition between the lights and the shades. In this case the chloride papers must be very considerably over-exposed, and then passed to the chloride of gold and the hyposulphite of soda, without paying attention to the intensity of the shades. After being slightly washed they are treated in the bath in question. The details of the shades now gradually appear, and the picture becomes harmonised. When taken out of the bath it must be copiously washed. It is advisable to cover the cyanide bath with a transparent glass, in order to avoid breathing its unwholesome exhalations.

I had nothing to tell you when I commenced, and now, I perceive, my letter has grown to an immoderate length; I will endeavour to make my subsequent communications shorter. May fortune favour me with wondrous news to announce!

ERNEST LACAN.

New Books.

Practical Hints on Photography: its Chemistry and its Manipulations. By J. B. HOCKIN.

London: Hockin & Co., Duke Street, Manchester Square.

IT is by no means uncommon to meet with a large amount of promise with a very small quantity of actual performance: the mountain in labour brings forth the ridiculous mouse too frequently to astonish any one, but we very seldom hear of the molehill producing an elephant.

* Our readers will be aware that we hold a very different opinion upon this point.—ED.

We do not assert that the latter phenomenon is to be witnessed in the present instance; but certainly Mr. Hockin not only fully acts up to his professions, but goes beyond them. He offers only chemistry and manipulation, and gives something of photographic optics in addition, though the latter is upon the principle *qui facit per alium facit per se*, being written, as we are informed in the book itself, by Mr. C. P. Symonds.

The present work, though not exactly a fourth edition, is an expansion of a modest pamphlet that has passed through three editions, and bears about the same proportion to its derivative as the "cell" to its "nucleus." The author is a practical chemist, whose "facts" may be received without question; and if his opinions based thereon are sometimes open to discussion, they at any rate deserve to be considered with respect. He is, indeed, pre-eminently a practical man, who, though not infallible, knows well what he is about; and should he chance to fall into error (as who does not at times?) is not ashamed to retrace his steps. If it be asked, "What has this to do with his book?" we say "much,"—it shows him to be a reliable guide.

We now proceed to give a short analysis of the contents of the work, and propose subsequently to make a few comments. The first sixteen pages consist of descriptions of various lenses and other pieces of apparatus, and are followed by a like number relating to the chemicals, manufacture of collodion, preparation of solutions, &c., with three more upon the dark and operating rooms. Manipulation occupies about forty pages, including the various modifications of the collodion processes wet and dry, as also a chapter on fogging and failures. Positive printing on paper, toning, paper negative processes, &c., all have attention, with eight pages of very practical matter "On Saving Residues." The optical part, by Mr. Symonds, next appears; then a chapter on chemical manipulation, and one on photographic chemicals, their preparation and analysis, concludes the work—the number of pages very aptly coinciding with the chemical equivalent of iodide of potassium, viz., 167.

Mr. Hockin differs materially from some authorities in a few fundamental principles of operation; for instance, he prohibits the use of acetic acid or fixed nitrate of silver in the bath, and recommends ammonia to neutralise an acid bath in preference to carbonate of soda, for all of which reasons are assigned, possibly not unanswerable, but good ones as far as they go. We have, however, an objection to take against a somewhat rash assertion relative to the use of cyanide of potassium as a fixing agent, which the author prefers very decidedly to hyposulphate of soda, both for positives and negatives. In producing the former, the use of cyanide is a necessity, in order to obtain the best results, but for negatives its employment is not imperative. "Many," says our author, "are prejudiced against this chemical on account of its being highly poisonous, but I think unnecessarily, *as it only becomes injurious if taken into the stomach:* its odour is by no means unpleasant, and *not at all injurious.*" The italics in the preceding quotation are ours, and we notice the paragraph because we think it a mistake likely to be mischievous.

A skilful and noted photographer, whose name is familiar to most of our readers, very nearly lost his hand by the use of this same chemical, the cyanide of potassium. It is true he had employed it for years with impunity, but the time came when, having a slight scratch on the finger, the cyanide attacked the vulnerable part—the finger swelled enormously, an open wound was established, the bone sloughed away, and at one moment serious fears were entertained by his medical attendant that amputation of the hand would have become necessary.

We are personally acquainted with a second case, showing that caution is requisite in dealing with this chemical. An eminent physician, who is an amateur photographer, having but little time to spare for practising the art, generally took large-sized positives, in consequence of their being completed at once. He noticed that whenever he had had a spell at photography, he generally suffered afterwards by an attack of the lungs, resembling incipient pneumonia. After repeatedly observing the same thing, he abandoned positives for negatives, using hyposulphate of soda instead of cyanide of potassium as a fixing agent, and the annoyance ceased. We think it but right to mention these facts —not to attempt to banish cyanide from our service, but to induce caution in its employment. Being forewarned is being forearmed.

On glancing through the pages we have marked for comment, we find their number so great that to notice all would require far more space than we can afford; there are so many useful hints that are also suggestive, that were we to dilate upon them we should probably tire our readers long ere we had come to a conclusion; before doing which, however, we would remark upon a matter alluded to by Mr. Symonds. This gentleman appears to think that lenses would be improved if made with elliptical or parabolic instead of spherical curves, and that opticians have been deterred from attempting their construction on account of the difficulties of manipulation. We do not agree in this view, and probably Mr. Symonds will change his opinion when he remembers that the *oblique rays* would suffer far more if transmitted through lenses with elliptical or parabolic curves than when their surfaces are spherical. The axial rays are comparatively easy to deal with,—it is the oblique ones that require the utmost consideration.

Mr. Hockin has adopted an arrangement of great convenience and utility in his book, in attaching to the principal paragraphs a sort of abstract, in the form of marginal references, which materially assist the student in finding what he seeks. We strongly recommend this useful little work to photographers that are or that wish to be: it will well repay its cost.

Correspondence.

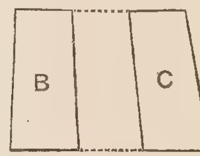
PHOTOGRAPHIC GOSSIP.

No. II.

To the Editor.

Sir,—In the last number of your Journal you particularly call the attention of your readers to Mr. Grubb's article *On Perspective and Distortion.* To me his ideas thereon appear by no means conclusive. In fig. 2, page 143, he gives a tower, B, with converging perpendiculars (is that not rather an Irishism?); and to show the absurdity of so drawing it, he "takes the liberty" of placing by its side another and *similar* tower, C, leaving between the two a space equal to the breadth of one such tower. Now I think he has taken too great a "liberty" in giving the tower C a separate and distinct vanishing point of its own; for it is quite impossible that, placed as described, it can have other than one and the same vanishing point as B, supposing but one point of view—which, by-the-by, Mr. Grubb so frequently puzzles us by calling "point of *sight*,"—a widely different matter. As to how we get "deeper into the dilemma by making the intermediate space converging," and, consequently, the tower C to lean inwards, I cannot perceive; for that follows as a natural consequence of the principles on which B is constructed, and if part is right or wrong, the whole is right or wrong, and must be disposed of accordingly. Supposing, as he does, for the sake of argument, the tower B to be correct; then in adding C, Mr. Grubb should have drawn it as below, so that the two will have but one vanishing point. His deduction, then, as regards the intermediate space, falls to the ground (perhaps he will tell me my towers stand a good chance of doing the same), and with it his "*argumentum ad absurdum.*"



I grant that it appears ridiculous to call this a correct representation of perpendicular objects; but it must be borne in mind that the drawing is here greatly exaggerated.

Looking down perpendicularly from a bridge, say thirty feet high, crossing a line of railway, so that the point of sight—the *real* point of sight this time—shall be in a position at right angles to such line, then, according to Mr. Grubb, the tramways should be drawn strictly parallel; but according to those who hold the converse opinion, they should be rendered as in the above diagram. Which I think right and which wrong I may endeavour to show in a future gossip after discussing other positions Mr. Grubb has taken up in his articles; but for the present *quantum stuffit* (you are fond of Latin quotations), as Mrs. Penelope Ann Spriggins would say.

Mr. C. J. Busk's paper *On the Action in the Dark of Engravings or Letterpress on Silver Sensitised Paper*, recals to my mind a fact of which I made a note some time since. I had occasion to leave a print in the pressure-frame for about twenty-four hours, and on taking it out found the back of the paper quite discoloured, excepting a portion accidentally protected by the corner of another piece of sensitised paper, thus plainly showing that the reducing influence came from *behind*. I repeated the experiment, keeping the frame altogether in my dark room, and met with a like result, whether black velvet or white paper was placed in contact with the sensitive paper. A piece of albumenised paper, sensitised, and "bronzed" in the sun, had no such reducing power. Hence, whenever I have to expose under a dense negative in a weak light, I invariably place a piece of "bronzed" paper between the sensitised paper and the back of the printing frame. In the inclosed specimen the white device has been protected by a design cut out of the "bronzed" paper, leaving the darkened portions to remain in contact with black velvet. The reduction was perceptible after twelve hours, and increased until in about four days it produced the depth of tone you perceive.

Mr. Israel Holdsworth favours us with some rather original suggestions. It is great nonsense, by his account, for people to talk so about different sorts of collodion. Anything does for him. He prefers Hanson's (whoever he may be), because it is cheapest. The notion that it is best when freshly made, is false—to his satisfaction. He seldom uses new, but likes it "deep in colour almost like treacle." Did he ever try golden syrup? When he permits the ether and alcohol to evaporate by leaving out the stopper of his bottle, the residue, I presume, is available for the dry collodion process. Mr. Hardwich has written about half-a-dozen papers on this article, and occupied as many evenings of the Photographic Society, besides letters, "comments," &c., without end, all on collodion—collodion! Why can he not, Mr. Holdsworth would probably ask, let us use Hanson's, or anybody's who can undersell him, and give us all sorts of valuable information instead? Mr. Holdsworth never meets with bad chemicals—lucky fellow! Only "keep your chemicals clean," and develop from a measure "crusted both inside and out with sediment," &c., and you may hope to produce—results.

In my last you make me imply that Mr. Robinson had thrown up a "tank" in his "small back yard," to serve as a model for the "top of a mountain." Mr. Robinson is a very clever manipulator, but I do not

see how he could have turned his tank to such account, unless, indeed, he had taken it after Turner, most awfully out of focus, and called it a Scotch mist. For "tank," read "*bank*."—I am, yours, &c.,

MICHAEL HANNAFORD.

[We perfectly coincide with Mr. Grubb's very conclusive arguments, but will leave him to reply, should he see fit to do so. Mr. Holdsworth "puts in an appearance" on his own account, so that we need not fight his battle.—Ed.]

THE COLLODION COMMITTEE.

To the Editor.

Sir,—Will you allow me space for a few remarks on the discussion at the last meeting of the Photographic Society? Mr. Malone made the general assertion, that the opposition to the collodion report came from those who were intimate with makers of collodion, and that he knew how to judge of criticism that must be interested. Pretty strong language from one who deprecates personality! Being one who has opposed and criticised the report, perhaps as strongly as any one, I beg, on my own behalf, and that of the Blackheath Society, which adopted my remarks, to deny the assertion, as far as we are concerned. Even supposing we were capable of being influenced by the unworthy motive attributed to us by Mr. Malone, we were happily kept out of temptation, not one person present during the discussion being so much as personally acquainted with a single maker of collodion. One other assertion of Mr. Malone I must also notice. It would be absurd in us to affect not to know that the "neighbouring society" to which Mr. Malone refers, is the Blackheath Photographic Society, as I believe no other society has criticised the report. Mr. Malone says we asserted that the parent society did not know what it was about. While repudiating altogether the parentage of the London Society, we distinctly deny that any such assertion was made or intended. A document, emanating not from the society, but from a very small section of it, was criticised because of its inconsistency, and because we thought it so worded as to be mischievous; but it was never asserted, even of the authors of that document, that they did not know what they were about, far less was such an assertion made of the society at large, which has not even now adopted the recommendations of the document in question. Much good has, however, come out of the late discussion, notwithstanding the endeavour to represent, or rather misrepresent, all criticism of the report, as an attack either on Mr. Hardwich or his collodion. We now learn the sense in which the words "superior excellence," and "unsurpassed sensibility," were used by the committee, viz., that the collodion is one of a class of good collodions, and that compared with the recollection of the majority of the committee of their former experience, it is as sensitive as any they ever used. Every one will, of course, judge for himself of the relative value of the recollection of these gentlemen, and the direct comparative experiments of Mr. Morgan, who asserts that under identically the same conditions he did obtain pictures in half the time with another collodion. While glad that the committee have thus explained their meaning, I cannot admit the correctness of Mr. Malone's illustration of the meaning of words. I quite agree that, if he were to say of any one that he was a man of superior mind, the assertion would be taken for what it was worth; but suppose a committee of the Royal Society to print a report, in which some individual was said to be a man of superior mind and one whose mathematical knowledge was unsurpassed, would any one think that this only meant that the individual in question had the average intellect of an F.R.S., and was merely a good mathematician? A *dictum* of a committee of the London Photographic Society ought to bear the same relation to collodion as the one I am supposing would to the subject imagined. We are next told that the contradictions noticed in the report only prove its justice, and arise from faults being mentioned in detail and excellence only generally. This reminds me of the story of the Irish woman, who, on being taxed with not being too particular in her morals, exclaimed, "Will, thin, though I am a thafe, and something more, I should like to see the hole ye can pick in me morals." Why, the faults so honestly detailed by the committee are utterly inconsistent with excellence of any sort. If the collodion be excellent, the faults are imaginary; if the faults exist, the collodion cannot be excellent. The most important information, however, obtained during the discussion was the reason that another formula sent in had not been examined, viz., that it recommended the use of Swedish filtering paper instead of cotton. Was one word said in the advertisement requesting formulæ to be submitted to the committee to intimate that the important question of what substance should be used in the manufacture of pyroxyline had already been decided, and that no formulæ should be examined that did not coincide with the preconceived notions of certain members of the committee? Had the *reason* come from any but a member of the committee I should have hesitated to believe it. On the general question Mr. Malone will find that it requires something more than the assertion that he knew something of paper-making in early life to convince the world that Berzelius, Régnault, and other chemists of celebrity, are mistaken when they call Swedish filtering paper *the type* of pure cellulose. I am quite prepared to maintain that you are far more likely to obtain a uniform substance by taking two sheets of Swedish paper out of two different reams, than by taking two samples of cotton out of two different bales. One other remark, and I have done. In his opening remarks, Mr. Hardwich said that his formula involved a "new principle," and promised to explain what it was at a later period of the evening. I have looked in vain for any such explanation in his later remarks; possibly the lateness of the hour made him forget it. I regret this the more, as I have failed to find anything like a new principle by a diligent study of the formula itself. Mr. Hardwich tells us what he considers the best proportions of acids, and the best temperature to work it. Some may agree with, and others differ from him, but the novelty of *principle* I cannot see.—I am, yours, &c. CHARLES HEISCH.

Middlesex Hospital, May 28, 1860.

PHOTOGRAPHIC MANIPULATION.

To the Editor.

Sir,—In your Journal of the 1st inst., in the report of the meeting of the South London Photographic Society of the 19th ult., I find some attention directed to a letter of mine which appeared in your issue of the 16th of the same month. That letter, I flattered myself, was written in such plain language that no one could misunderstand it who had sufficient intellect to enable him to take a photographic picture. It appears, however, that gentlemen of some professed attainments may read it with misapprehension. In reference thereto "Mr. Howard thought extreme carelessness seemed to be characteristic of some operators." Now, if Mr. Howard had read it with proper attention, he would have seen in the first paragraph that it professed to be a detail of lengthy "experience," written for the benefit of such as might comparatively lack that important desideratum. Pray, what could I or anyone else mean by a mode of manipulation founded upon "experience," but that *careful* observation had demonstrated a mode of accomplishing the end proposed, which it was found advisable to practice? I need not tell you that, to take a photograph successfully, the combined action of specific natural laws requires to be effected. Now, as every operator in any art or science is aware, there is a direct as well as a roundabout way of accomplishing the intended purpose: even extraordinary care succeeded by failure, and seeming carelessness attended with success. When the latter is the case, the apparent carelessness is such only to the uninitiated, for the result is proof positive that all the required conditions have been complied with, and that whatever more is done is roundabout and superfluous. Therefore, that which Mr. Howard characterises as "carelessness" may, for aught he knows, and *is* to my certain knowledge, specific and scientific exactitude. When I tell him how simply and successfully I go about my business he ought to believe me, or at least hold his judgment in suspense till he receive more light on the subject, unless he is already able to demonstrate its impossibility, which, of course, *I* know he is not. I should not dispute his word if he were to tell me that it required from him, to be successful, three times as much care as I bestow, for I know it to be both possible and probable.

I was aware when I wrote the letter that it was somewhat heterodox, and therefore was prepared to find it frowned upon by the devotees of orthodox routine. Nevertheless I was not at all deterred from stating the truth, for I was convinced that there was a great deal of photographic quackery afloat, which I hate, as I hate all quackery.

If the report be correct, Mr. Simpson opposed my letter by an erroneous statement, namely, that I said I had "no failures." What I did say does not admit of a dispute; that your printed columns at once decide. The words are these:—"I seldom have a failure from any cause, except in misjudging of the light." What, I ask, can be plainer? Mr. Simpson may now see, if he choose, not only that I did not say I had "no failures," but that I specified one annoying source of failure, and by implication acknowledged others. Mr. Simpson appears also to have made himself merry at my expense, as he supposed, and at the same time displayed, in addition to his photographic knowledge, his "logical" attainments. Well, let him get his laughing done, and then we shall see what his logic is worth.

He says:—"When a man of such a stamp *said he had no failures* it is more than probable that less partial judges would say he had no successes." Here Mr. Simpson, like myself, is "very logical." He starts with false premises, as I have shown, and, *ergo*, arrives at a false inference. Let what he says be taken in the form of a syllogism:—

I (Mr. Simpson) make an erroneous statement; a person cannot be successful respecting whom an erroneous statement is made; therefore Israel Holdsworth cannot be successful!

Again, he says that I "not only asserted that 'a deal of nonsense is written,' but accompanied the assertion with a most conclusive proof of the fact."

"Proof of the fact!" does Mr. Simpson say? What nonsense! Before he had set himself up as a scientific censor, I think he would have shown a better understanding, or more modesty at least, if he had made himself acquainted with some of the leading words in its vocabulary. He ought to have known that a "fact" does not admit of "proof," but of demonstration; that *truth* only can be "proved." Whatever be his attainments in other respects, I think it is clear that his critical acumen would not be injured by a re-perusal of his school-books.

But let us see what the statement means. It must have been intended either as literal or figurative. If literal, it makes his logic turn upon himself in the form of "nonsense," by admitting the truth of what I stated. For, let us logicify it, and it will stand thus:—Israel Holdsworth says, "a deal of nonsense is written; he has accompanied the assertion

with a most conclusive proof of the fact;" therefore "less partial judges would say he had no successes!" Logic! Bah!

If his language was intended as figurative—irony—I would ask him, since the thing is not self-evident, why he did not show my statements to be erroneous? I answer, "It was more easy to laugh than to do that." But I would remind Mr. Simpson that matters of science are not to be proved either true or false with a laugh, and that, at an earlier stage of the meeting, the Secretary threw out a suggestion by which he might have profited, namely, "that the substitution of ridicule for argument was not consistent with either good taste or sound sense."—Yours, &c.

Leeds, May 7th, 1860. ISRAEL HOLDSWORTH.

[We would suggest to Mr. Holdsworth that a simple and effective way of turning the laugh against his opponent would be to forward a specimen or two for exhibition at the next meeting of the Society, to the worthy Secretary, Mr. Wall. We can promise him that he will receive full justice and a fair field, with every reasonable favour.—Ed.]

WET OR DRY?

To the Editor.

Sir,—I should feel much obliged to you if you would inform me, in your next number, at *what shop in London* I can procure Dancer's developing dishes for stereoscopic plates, referred to by Mr. Hardwich at page 399 of his Work on Photographic Chemistry.

You imply, in your answer to "A Persevering Amateur," that the dry process is more difficult than the wet. I suppose you mean if the amateur is to prepare his own plates; otherwise surely such is not the case?—I am, yours, &c. S. T. COPLEY.

[1. Murray and Heath, Piccadilly, or Bolton and Barnitt, Holborn Bars, keep them, and probably many other dealers in apparatus.

2. We should scarcely consider any one who *habitually* works upon dry plates prepared for him by another worthy of being described as a *photographer*, but merely a dabbler in photography. Certainly to succeed in the dry processes the operator has more to do than with the wet ones, and the chances of failure are increased: hence our reply.—Ed.]

PHOTOGRAPHY IN ITS APPLICATION TO SCIENCE.

To the Editor.

Sir,—Can you inform me whether any work or paper has been yet published showing how far photography may be made subservient in delineating, with that unerring truthfulness of which it is capable, the phenomena and objects of the chemical, physical, and natural history sciences?—I am, yours, &c.,

London, May 28, 1860. F.R.S.

[Some time back a work of the kind you are inquiring for was *announced* for publication, to be illustrated by photographs and stereographs, but we believe it has not *yet* made its appearance. Besides an article on the subject, by the Rev. F. F. Statham, in our present number, we have in recollection a paper by Mr. S. Highley, *On the Application of Photography to the Illustration of Works on Microscopy, Natural History, Medical Science, &c.*, in the volume of the *Microscopical Journal* for 1853; also a more extended paper on the same subject, and another *On the Application of Photography to War Purposes in the Army and Navy*, illustrated by special apparatus, read before the Liverpool meeting of the British Association.—See *Reports*, vol. xxiv., 1854.—Ed.]

MRS. SPRIGGINS ON PATCHWORK.

To the Editor.

Sir,—Oh! my! you can't emagin wot wos my felinks wen on the last 15th of April as ever wos, the two pair back's brother came in a-larfing like everythink and says, says he (with The British Journal of Photography a-sticking hout of his pocket), "Mrs. Spriggins," says he, "ITS IN," says he, "and won't you be a suspicious caracter now and no mistake" (which wos his way of compressing hisself. "Mr. Snooks," says I, "don't compose upon me, *don't*;" and then wot should he show me but my hone blessed name as large as everythink in real print. Wel! I could'nt help larfing hout loud, and come all over of a heat like, and "Oh!" says I, "wot *will* Jim say wen he comes home?" says I. And wen I wos by myself agin, I says to myself, "It don't magnify a bit," says I, "for Ive received a good edication and I'll be a littery author wot writes for books." And says Jim, which a better lad never stepped in shoo lether after super with his glass of grog before bed, with his pipe, says he, "Do." So I got Mr. Snooks, which reeds butiful, and so he dus to reed me sumthink hout of one of his books about a Mr. Robinson Crusoe wot noo sumbody with a forrin name in french which Mr. Snooks could'nt talk, so he left that hout, and about how he went two thousand years ago and composed "five of the most butiful girls of the town" into "a single figger" which he said was one of the dim conditions of iniquity, or sumthink of that sort: which *he* wanted them to do the same thing, only different like, in photography. And wen he sed as how he joined together a lot of bits of girls and made one hole one, my hies lighted up and I felt I had a hidear, which here it is Mr. Editor, which a real gentleman you is and so says all of hus as as they sings in the song.

Now my idear is—PATCHWORK!

And I says with Mr. Robinson Crusoe, I says "It is rather singular that so little has been done in this branch" becos "the method was practised for many years" by my Grandmother and her patchwork quilt which ansum it is *now*, is on the two pair back's bed at this werry time. Now I asks in the words of Robinson Crusoe and I says how is this? "It cannot be that we have no hartists among us; we cannot hall be so devoted to science that we discard hart" and then again he says, and so do I, says he "It is possible that prints from several negatives combined" (or as I says pieces from the rag bag) "do not pay so well commercially as proofs from a single glass; but that should not prevent enthusiastic followers of such a pleasing art from pushing it to its greatest extent; and its application to the highest art purposes is certain." Wel! praps the quilts hall in a piece is cheaper after hall, but wot's that to the *hart* of patchwork? thats wot I says, and so does Robinson Crusoe!

Now all I says is this ere, let that there Photographic Society of Scotland as they calls it offer a prize for the best piece of patchwork and I'm the *hartist* that will sho my work for it and then let 'em jest pay my railway carridge and find me a nights lodging and bored, which it must be fit for a eyely respectable female mind you and see if I don't reed em a paper which will "give them some information on the method I employ in producing" patchwork quilts from a whole lot of little bits, thats all.

Hopin you and your family are well as this leaves me at present I am yours unseterer, PENELOPE ANN SPRIGGINS.

P.S. Mr. Snooks says it wasn't Robinson *Crusoe* but sumboddy else which was werry much at see.

ANSWERS TO CORRESPONDENTS.

☞ Foreign Correspondence.—M. Lacan, Editor of *La Lumière*, it will be seen, is now our Correspondent at Paris.

Amateur (Shields).—Use albumenised paper if you want minute detail.

Geo. Williamson.—Send the particulars, and we will advise you what to do.

R. A.—The *first* on your list stands the highest, and then the *third*, the remainder are a long way behind. We could, however, name a better than either.

Faint and Flat.—"Any port in a storm." You did the best you could under the circumstances.

Amateur (Edinburgh).—You can procure any No. of the Journal from Mr. Wood. As to dry processes, their name is legion: we recommend, however, Fothergill's or Taupenot's processes in preference to any others for amateurs. Dr. Norris's process is also excellent.

Perplexed.—We do not wonder at it. Depth of focus is all fudge, which accounts for your negative being all smudge. If you want to delineate objects in widely differing planes, the only scientific way of proceeding is to employ a very sharp lens, and *use a small aperture*.

Holder.—We do not think that the kind you mention to be compared to a good *pneumatic* holder. The parts which touch the edge of the plate must come in contact with the solutions, and this is not the case with the pneumatic form. You must remember, however, that there are good and bad ones of the latter kind; but we know of three different forms that are just—perfect.

J. Smith.—Either your toning bath must have been nearly exhausted, or, what is more probable, the sensitising bath (nit. silver) had been so reduced in strength by use, that the amount of *free* nitrate of silver left on the paper was insufficient to allow your proof, when taken from the pressure frame, to have reached the bronzed stage in the shadows, in which case there would not have been sufficient energy to reduce the gold.

A Manchester Photographer.—A specific gravity bottle, or hydrometer, is of *no use* for testing the strength of the nitrate bath after use: your conjecture is correct. An instrument, under the name of an argentometer, is, however, sold by Mr. Hughes, of Oxford Street, Hockin & Co., Duke Street, Manchester Square, Horne & Thornthwaite, Newgate Street, London, and several other dealers, which perfectly answers the purpose, as the result depends upon the production of chloride of silver. The action is both simple and efficacious.

J. L.—Your plan is perfectly intelligible. Remove the woodwork on the west side, and paint the dwarf wall on the same side as pure a white as you can, the object being to reflect as much light on that side as possible. Place your camera as near to the north wall as you can, and *bring forward* your sitter and background several feet—say from four to six feet. The screen over head (which should be only of white calico) should be lowered a couple, or even three feet. Try this, and we do not think you will have to complain of flatness.

R. Mulock.—Proto-nitrate of iron is made thus:—Take protosulphate of iron 320 grains, and dissolve it in 1 oz. of hot water, and in like manner 300 grains of nitrate of barytes in 3 oz. of hot water; mix and stir—a thick white precipitate will fall down (which is sulphate of barytes), filter out through a paper filter, and preserve the clear liquid, which should be of a delicate pale green colour, in a closely stoppered bottle for use. It will not keep long, particularly if the bottle be not quite full. It should be used without any acetic or other acid; and when freshly made, the positives developed with it are of a brilliant metallic hue, like frosted silver.

C. J. (Birkenhead.)—We are obliged for the proofs, which have been duly received. You might have used a larger stop without detriment, and materially reduced the exposure. Generally, the maker of your lens cuts down the aperture more than necessary, being over careful of his reputation for sharpness. Do not be afraid of using a large aperture (except where there is much difference between the nearer and more distant objects), and you will get more vigorous results, and with much less exposure. You have succeeded very well with it, but we do not much admire the process you have used, regarding it as inferior to the Fothergill one, and quite as troublesome. You will probably cover your *small dots* easily by adding a little alcohol to the water.

Bothering Amateur.—By "a fresh solution of hypo." is meant a portion that has not been used for fixing on a previous occasion. There seems to be no tendency to decomposition of a hypo. solution until one part, by weight, of chloride of silver has been imparted to three of hyposulphite of soda—then hyposulphite of silver is precipitated in a crystalline state, and chloride of sodium remains in solution—that is, if the prints have been previously freed from nitrate of silver by washing before being placed in the hypo.-bath. Read Mr. Dawson's paper in our number for May 1st, and our Leader for May 15th. Add twenty minims of alcohol to the developer you name, *if it will not flow*. Iron developer for intensifying process:—Water one ounce; proto-sulphate of iron fifteen grains; glacial acetic acid fifteen minims. The linseed tea preservative process is simple, and would meet your present requirements. We have heard this process much lauded by a professional photographer of great experience.

Joseph Day.—From what you have stated in your present and former communications we believe your nitrate bath solution is irremediably at fault, through your having introduced *various* matters into it, and keeping it in a gutta-percha trough made of impure or inferior material; we, therefore, recommend you, as the shortest way to get out of your difficulties, to precipitate the silver of your nitrate bath by adding to it a solution of common salt; dispose of the chloride of silver thrown down to a photographic chemist, and make a fresh solution of nitrate of silver In future keep your bath solutions, for negative and positive collodions, distinct. Thoroughly cleanse your gutta-percha trough, and coat the inside with shellac varnish; use a glass dipper. By attenti n to these points you will probably avoid the fogged and dirty plates you complain of. We should, however, advise you to study some such cheap guide book as that lately published by Mr. Hockin. There is no objection to the use of pure spirits of wine for plate cleaning, but add some precipitated chalk or whiting. If your friend *cannot* afford to buy a lens, we really *cannot* assist him in that matter. The queries at the end of your note are like your plates—foggy! Put them in a clearer form and we shall be happy to answer them.

⁂ In Type.—A critical notice of Mr. Rodger's Stereographs, letter of "A. Y.," and several other communications.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 120, Vol. VII.—JUNE 15, 1860.

It has been frequently remarked that more information is sometimes gained by failure than by a successful operation. The reason is evident: failure leads to inquiry concerning its cause, while most persons are content with success, and ask no questions. In like manner it may be asserted that the enunciation of a scientific error occasionally leads to a knowledge of facts that would probably have otherwise remained for some further time in obscurity. We have now before us a case in point, in the valuable and highly interesting facts brought to light by Mr. Dawson, in consequence of a too hasty adoption of an untenable theory by gentlemen enjoying a very high reputation amongst their photographic brethren in the French metropolis. It is unfortunate that the most energetic workers in scientific investigations are precisely those that are liable to fall into a mistake of the kind above alluded to; but as the advance of the art is no doubt the ruling principle in their operations, as a matter of course, when convinced of an error, the gentlemen alluded to will in all probability seek to arrest the promulgation of a faulty principle put in circulation upon their authority.

We publish in the current number of this Journal an account of further experiments made by Mr. Dawson in reference to the supposed rapid saturation of hyposulphite of soda with hyposulphite of silver — experiments which not only fully confirm all that he has advanced in his previous paper on the subject, but which also tend to demonstrate the probable source of another annoyance to which photographers are sometimes exposed, the production of what have been aptly termed "measly spots" in paper positives. From observations that we had personally made with regard to this kind of inconvenience, we *conjectured* that it was owing to a partial combination of the sizing material of the paper with an unstable compound of silver. Mr. Dawson has gone further. He has plainly shown that this conjecture was correct; and not only so, but he has very ingeniously exhibited the probable *rationale* of the phenomenon, for the details of which we must refer our readers to the paper itself. We can promise those who are interested in the scientific branch of photography that it will well repay careful consideration.

In connexion with the subject of Mr. Dawson's paper we have the pleasure also of publishing one by Mr. Oakeshot, to whom we are in some measure indebted for the investigations of Mr. Hardwich and Mr. Dawson, which were undertaken in consequence of a letter from him, read by one of the members of the North London Photographic Association at a meeting held a short time back. Mr. Oakeshot's paper establishes several interesting points connected with positive printing, viz., that a new hyposulphite bath has less tendency to part with a portion of its sulphur than one which has been previously used; that fifteen minutes' immersion in the fixing bath is amply sufficient for its effective action upon the prints; that the treatment of the latter with boiling water is a pretty severe test of the efficiency of the hyposulphite of soda employed. It also equally demonstrates that the alarm sounded by our continental friends was a needless one.

Before quitting this subject we have a word of caution to offer in reference to the general adoption of the practice of treating proofs to a hot bath, viz., that such a proceeding completely removes also the sizing material of the paper, which, before the prints are mounted, should be restored, as they are otherwise apt to assume a kind of feeble, worn-out aspect, and present a very unsightly appearance when the adhesive material used in mounting possesses any depth of colour. If the prints are mounted with the aid of not over-thick paste, or clear solution of isinglass or gelatine, either of these will act also as a size; but if other adhesive matter be preferred, it is advisable previously to restore the sizing by floating the proofs on a warm weak solution of gelatine — one containing about three grains to the ounce of water answers very well. The object of this treatment is to prevent the penetration of the mounting solution.

We perceive, from a paragraph in the last number of the organ of the French Photographic Society, that until very recently our continental brethren have been puzzled by the appearance in the English journals of formulæ for collodion directing the use of *methylated* alcohol — a substance with which they have been happily unacquainted, and with which we trust they may be fortunate enough to remain so; for we are convinced that its use is but false economy, its tendency to produce incurable disorder of the sensitising bath being now pretty conclusively demonstrated. It is not surprising that French photographers should be somewhat in the dark about it, seeing that in all processes in which alcohol plays an important part they possess a very great advantage over their English competitors, owing to their freedom from the *onus* of a heavy Excise duty. Although it is stated in the paragraph alluded to that methylated alcohol is employed as a *cheap* substitute for the pure article, to our French friends the cause of the difference in cost is evidently still enveloped in mystery—and well it may be so, for the wilful contamination must appear to them as little short of an act of insanity.

At the last meeting of the Photographic Society, as will be seen by our report, a paper by Mr. Dallmeyer, bearing the title, *On Distortion as Produced by the Present Forms of View Lenses, and on an Improved Construction of Lens Free from this Defect,*" was read. Knowing the author of the paper to be a clever practical and theoretical optician we attended the meeting, anticipating some important addition to our optical resources as applied to photography. But, alas! we were destined to be grievously disappointed. On subsequently criticising the title of the paper, we perceived that, but for one word—" improved "—it might possibly have been contended that every promise held out had been redeemed, but the introduction of that one word is, in our opinion, fatal to the establishment of such a proposition; and even omitting it, if the letter could have been regarded as fulfilled, the spirit certainly could not. It will appear almost incredible to our readers when we inform them that not even the most trifling novelty of principle or construction was introduced.

The lens submitted was simply a good-sized *ordinary portrait combination*, with sliding diaphragms between the back and front constituents—neither more nor less; and with regard to the specimens exhibited, their smallness of size was preposterously disproportionate to that of the lens with which they were produced. We wish it to be distinctly understood that neither to the lens nor to the paper itself have we any other objections to make than those already stated; but as we well know the great interest felt by photographers generally in the subject before us, we cannot, consistently with our duty, abstain from recording a strong protest against the adoption of a misleading title, such as that of the paper on which we are treating.

With regard to the subject matter of the paper itself, we should have given an abstract of it but for the fact that the whole substance of it has been already published in this Journal repeatedly, but especially at the time when the orthoscopic lens was first introduced (about two years since), and again when the Lens Testing Committee of the Photographic Society of Scotland issued its report. On both of these occasions we entered pretty fully into the particulars of this subject in our leaders. Those of our readers who will take the trouble to refer back will perceive that we pointed out, at the times specified, that the *kind* of distortion produced is dependent upon the position of the stop, which, in the ordinary single landscape lens, is placed at a distance in front, causing a square figure to be delineated as one somewhat barrel-shaped; while the orthographic lens, having the stop behind the positive combination, produces on the contrary the hour-glass kind of distortion, as regards what should be rectangular figures. We shall probably allude further to this subject in our next.

We desire to direct attention to two notices in connexion with the South London Photographic Society, which will be found in the usual column of the present number. We have also to remark that this Journal being the official organ of several societies, the members of which are each supplied with a copy, it is in contemplation, by the managing body of one of the societies, to offer the option to any member desiring it of receiving instead of the Journal an additional photograph to that already given, in order to meet the cases where gentlemen belong to more than one society, and thus receive duplicate or triplicate copies of the Journal. We cannot be accused of interested motives in recommending the regulation to our other constituents.

ON THE MUTUAL REACTION OF CHLORIDE OF SILVER AND HYPOSULPHITE OF SODA.

An Inquiry into the Cause of the "Measly Spots" in Positive Proofs.

By George Dawson.

[Read at a meeting of the North London Photographic Association, May 30, 1860.]

In the absence of other matter for discussion this evening, I propose to call your attention to a few concluding experiments and observations I have made, since our last meeting, on the solubility of chloride of silver in hyposulphite of soda. There is, indeed, but little to add to what I have already stated, except the confirmatory evidence of a repetition of my experiments with purer materials and with more decided results: my remarks, therefore, shall be brief, but I trust thoroughly conclusive. Allow me this opportunity of thanking you for your kind forbearance and patient attention on a former occasion, while occupying so much time which might otherwise have been employed in more pleasurable discussion.

I have been attempting to demonstrate a truth which I believe few practical photographers ever doubted, viz., the great solubility of pure chloride of silver in hyposulphite of soda, without producing in the solvent any tendency to the formation of crystals or other deleterious matter in the texture or on the surface of the paper immersed therein. We all know that a deposit, when it does occur, arises from causes widely different, some of which I shall afterwards explain to you. The challenge lately sent us by a photographer of great practical experience compelled the Society, in justice to itself, to discuss the question. He, like a few others, became alarmed in consequence of a contrary statement published by men said to be of high reputation in science, but who, in their researches relative to the subject of positive printing at least, have added but little to our stock of knowledge, and that little appears to be anything but correct. Their assertion (which I have been endeavouring to combat) of the extraordinary fallacy that the supernatant liquor of the crystalline deposit from hyposulphite of soda, saturated with pure chloride of silver, represents a solution of Herschel's salt $Ag.\,O, S_2\,O_2 + 2\,(Na.\,O, S_2\,O_2)$ is both chemically and practically erroneous. This their own analysis clearly shows. In other respects, whenever they have made any valuable suggestion I find the same fact has been before stated by Mr. Hardwich, in one or other of his many papers, unfortunately scattered over several periodicals. The real facts are (and any one with a tolerable modicum of patience may verify them for himself) as follow:—

Solution of hyposulphite of soda, of any strength, will dissolve chloride of silver, till no trace whatever, either of silver or of hyposulphite of any kind, is left in the original solution, but which will contain only chloride of sodium, the hyposulphurous acid and silver having combined to form hyposulphite of silver, which falls in the form of white, crystalline, opaque, heavy grains.

Before testing the remaining solution for the presence of hyposulphites and silver, it is necessary to submit it for an hour or two to a strong light; for it must be borne in mind that chloride of silver is slightly soluble in chloride of sodium. The action of the light throws down a small quantity not of hyposulphite or sulphide of silver, but of semi-reduced subchloride in an extremely fine state of division. The following tests will exhibit the nature of the liquid:—

Boiled with hydrochloric acid, no cloudiness nor precipitate being produced shows the absence of a hyposulphite. Hydrosulphuric acid or hydrosulphate of ammonia does not cause any trace of a precipitate, showing the absence of silver.

A drop evaporated on glass under the microscope exhibits cubical crystals precisely similar to those of an artificial solution of chloride of sodium, and on platinum wire communicates to the blowpipe flame the same intensely yellow colour peculiar to the salts of sodium. Lastly, the addition of nitrate of silver produces pure chloride of silver.

As regards the precipitate, viz., the hyposulphite of silver, it may be dried at a low temperature in the dark, and preserved possibly for any length of time: it is soluble in hyposulphite of soda, the solution soon beginning to decompose. It is decomposed also by heat, light, water, and even in the dark when the atmosphere is moist, the decomposition in every case ending in sulphide of silver.

Not to enter into more chemical details as to the foundation of my belief, I may now, I think, confidently state as a fact what I had only previously surmised, that pure hyposulphite of silver is formed by the gradual addition of one equivalent of chloride of silver ($Ag.\,Cl. = 144$) to one of hyposulphite of soda ($Na.\,O, S_2\,O_2 + 5\,HO. = 124$), the decomposition and recomposition being, in chemical language, expressed by the formula—

$$\underbrace{Ag.\,Cl.}_{\text{Chlor. of silver.}} + \underbrace{Na.\,O, S_2\,O_2}_{\text{Hyposulp. of soda.}} = \underbrace{Ag.\,O, S_2\,O_2}_{\text{Hyposulp. of silver.}} + \underbrace{Na.\,Cl.}_{\text{Chlor. of sodium.}}$$

With these remarks I have done, and I trust for ever, with this part of the fixing theory. I shall now advert, as pertinent to the present question, to a few practical and rude facts which will every now and then thrust themselves forward on our notice in the shape of imperfectly fixed prints of various degrees and kinds. The general question is too wide for one evening's discussion; and indeed I have not given sufficient attention to it in all its bearings to venture on pronouncing a decided opinion on many cases I have seen. We have enough before us at present in endeavouring to investigate the causes of failure in one class, several specimens of which were exhibited at our April meeting, and gave rise to considerable discussion. These prints were recognised by many members as old acquaintances, which they had more than once unfortunately stumbled across in the course of their own experience. They have been aptly denominated by Mr. Hughes, I think, the *measly class*, showing by transmitted light opaque blotches in the interior of the paper, and on the surface much flatness and a yellowish tone. The specimens I have examined were—two or three of those you have already seen—in a highly developed stage of the disease. We had no information to guide us, further than the fact that they were "printed upon paper kept some time after being albumenised and fixed in new hypo. which soon decomposed." The absence of full information was to some extent desirable; for, had we possessed more, it is probable we should have been satisfied with tracing to its source the particular fault before us, without discussing other causes which may have produced a like result.

In the prints then exhibited the paper was very thick, highly albumenised, and of a particularly non-absorbent character. On carefully removing the albumen with a sharp knife I found directly underneath, and entangled in the interior fibre of the paper, a plentiful crop of a yellowish-brown substance, easily collected and removed. It was insoluble in the strongest hypo., also in sulphuric and hydrochloric acids, and but slightly soluble in nitric acid. Under the blowpipe it was easily reduced into metallic silver. Boiled in water it turned quite black, with the evolution of sulphurous acid. And this same change, or one nearly analagous to it, goes on slowly but surely in the picture itself at ordinary temperatures, especially in the presence of moisture—with this difference, that the sulphur arising from the measly blotches in the interior does not escape, but finding on the surface of the paper more silver wherewith to combine, actually does so, and finally transmutes the whole picture into one uniform dirty yellowish-brown colour. There can be little doubt, therefore, that the substance of these *measles* consisted of either hyposulphite of silver in a state of decomposition, or of sulphide of silver, or (as I strongly suspect) of an organic silver salt, formed by the albumen and sizing of the paper.

The important question now arises, what produces in the texture of the paper a deposit which gives to a photograph this hideous appearance, and eventually destroys it?

The effect may be produced artificially in several ways. Many, I dare say, will be suggested in the course of the evening, and some may still exist which "are not dreamt of in our philosophy." For how can we know what impurities in the sizing, in the bleaching, in the very fibre even of the paper, the maker accidentally or otherwise may have placed there? This much is certain, the quality of the paper exercises an important part in facilitating this formation. For out of upwards of ten different kinds of paper tried by me, I have only in two instances been able to induce artificially an immediate attack of the measles by a *fresh* solution of hyposulphite of soda of a strength of ten per cent. It is probable some of the other papers treated in the same way will eventually manifest similar symptoms. In the meantime they are uniformly translucent by transmitted light; and therefore if the deposit consists of hyposulphite of silver, no decomposition has set in, and it may be dissolved by fresh hypo. One mode of procedure in order to produce the defect was this:—Three papers were excited and printed in the usual way, washed to get rid of free nitrate. They were then pressed closely together so as to form one mass, and immersed in the hypo. for twenty minutes. At the end of this time the middle print, through its whole texture, was sadly diseased, with a tendency to get worse and worse, even in fresh hypo. Another piece of the same paper, floated on hypo., produced similar effects; so also when immersed for a very short time.

A second cause, independent of that previously mentioned, is the use of stale albumen, a practice, I fear, but too common among the albumenising fraternity. A sheet of paper prepared with this must almost under any circumstances develop sulphide of silver; and this deposit may be formed before immersion in the hypo. bath, or must have acquired a strong tendency to form because of the sulphuretted hydrogen set free from the decomposing albumen and retained in the interior spongy fibres of the paper.

If the hypo. solution be weak, and the paper employed be of a thick, highly-sized, non-absorbent nature, with a rather thick coating of albumen, we have here again another source of danger. To illustrate this I have brought some pieces of albumen, a few of which have been in weak salt and water for some minutes, others not so previously to being soaked for five minutes in strong solution of nitrate of silver. One side of each was exposed to the action of light. They were afterwards washed for several hours in running water under a tap, and also treated with salt water to destroy, as far as possible, free nitrate of silver. Finally, they were stirred about for one hour in the strongest hypo. and well washed. You will observe from cutting transversely through one of these slices, that the nitrate of silver has penetrated farther in five minutes than the hypo. in one hour—that so far as the latter has penetrated in sufficient force the former has been almost completely removed. Adjoining this, and towards the centre of the slice, enough of the hypo. has reached to convert the nitrate or albuminate of silver into incipient sulphide, at first of a yellowish colour, but after a few days, or immediately on the application of heat, becoming quite black.

In using thick non-absorbent paper, highly charged with argento-organic compounds, I think, from the examples before you, the danger must be very obvious. For in order to attack the chloride and albuminate or other organic salt of silver in the interior, the hypo. must filter through the albumen on the surface, or through the slowly absorbent fibre of the paper; and this under unfavourable circumstances may be only in quantity sufficient to form hyposulphite of silver of a very unstable kind, which, unless immediately removed by fresh hypo. passes into the insoluble sulphide.

I have not had time to examine how far the presence of free nitrate of silver in the paper, or of acidity and partial decomposition of the hypo. bath, assist in the formation of these blotches. Combined with the causes above mentioned the predisposing influence must be large, especially in decomposing the hyposulphite of silver, immediately on its formation, into another and highly insoluble compound.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 6.

At the present season, when the practice of dry collodion photography is at its height, we shall persevere in our attempts to ventilate the subject in the most complete manner, in order that the *pros* and *cons* of every process may be understood. In affirming, as we did in our last, that the presence of albuminous bodies in the preservative agent had a tendency to prevent fogging and irregular reduction of silver on the non-exposed portions of the plate, we did not intend to assert that such a protective effect is confined to that particular class of bodies, or to say that the presence of nitrogen in the protecting substance is essential. So far from such being the case, it seems that many of those organic subtancess which reduce nitrate of silver to the metallic state have the same tendency to prevent fogging as that exhibited by albumen. Thus, if we preserve a washed collodion plate with cane sugar, we find it more liable to give a cloudy picture than when grape sugar is used; or if we employ Fothergill's process, and observe that the picture developes in an indistinct or misty manner, we may often remedy the defect by applying a final wash of gallic acid, after the albumen: this will brighten the negative and preserve the shadows clean and transparent. A particular condition of the sensitive film is required to render it susceptible of a strong actinic impression. If this exists in the collodion itself, either from the pyroxyline having been made in a certain way or the collodion having been kept in the iodised state, then very little artificial aid will be required, and all that the preservative will be called upon to do will be to keep the film in the proper physical state. In such a case the exact nature of the preservative is certainly not of the same importance, and a solution of cane sugar, twenty grains to the ounce, will answer the purpose and give a clean picture. When, however, the collodion is wanting in those qualities which cause the exposed plate to exert a strong attraction towards the particles of reduced silver, and draw them off, so to speak, to the image, then those particles will be thrown down irregularly and the developer will become turbid. The caseine in serum of milk and the coagulable matter in infusion of malt are both likely to prevent this turbidity, as is also the grape sugar in the latter liquid.

At the last meeting of the South London Photographic Association the subject of dry processes was brought forward, and we have since been thinking over the remarks made by Mr. Ackland upon that occasion. He speaks of the difference between a porous and a non-porous collodion. A friend of ours has been in the habit of examining collodions as regards their porosity in the following manner:—He exposes the sensitive plate with the *glass side* towards the object, so as to form the latent picture upon the *under surface* of the collodion. Then, if the film be very horny and impenetrable, the developer will scarcely act; but if, on the other hand, it be open and porous, the reduction will take place as usual. We ourselves, in giving an opinion on a porous collodion, should be disposed to inquire how the porosity was produced. If it was brought about by the gradual liquifying action of an alkali, or an alkaline iodide, the collodion will be likely to give an intense negative in Fothergill's process; but if, on the other hand, the porosity of the collodion be due to the use of pyroxyline made with very weak nitric acid, then the negative will be feeble. Happening to have by us a sample of collodion made with this latter pyroxyline, we sent it to Mr. Ackland to try, feeling sure at the same time that he would not be pleased with it. His answer was what we anticipated, thanking us for the trouble we had taken, but stating that the collodion did not succeed. Since then a gentleman from a more distant part of the country has requested that we would assist him in producing a sample of this "porous pyroxyline," so termed; but we have declined doing so, feeling that it would not answer

his purpose. If these papers should meet his eye, and he be still desirous of preparing a pyroxyline which will not dry up very rapidly after sensitising, we advise him to work with a nitrosulphuric acid containing a medium proportion of water, and to raise the temperature to 170° or 180° F. In this way he will get what what he wants as regards the physical properties mentioned, without reducing the intensity of the pyroxyline in that very complete manner which nitric acid in a greater state of dilution with water tends to do.

Mr. Ackland speaks of transparent markings at the place where the albumen was poured on. Do such markings arise from a solvent action exerted by the albumen itself upon the precipitated albuminate of silver? It occurred to us that it might be so, from our having observed that the precipitate first produced on adding a few drops of diluted solution of nitrate of silver to the Fothergill albumen liquid disappears on stirring. We ask, therefore, in the next place, what would be the effect of treating the prepared Fothergill plate in the wet state with several fresh portions of albumen? Would the albuminate of silver first thrown down be afterwards taken up again? or would its combination with the iodide of silver —for we may now be certain that there exists such a combination— enable it to withstand the excess of albumen? If so, again we ask, what is the cause of the transparent spot observed by Mr. Ackland? In our own practice we have not seen this spot, and are unable to conjecture why it should occur with old collodion and not with newly iodised collodion.

We are still of opinion that the Fothergill process, as compared with some other dry processes, is slow of development. At first we thought that this must be due to the shrinking of the collodion in drying, which happens in that process from the excess of albumen having been washed away. We therefore obviated this by preparing a Fothergill plate in the usual manner, and then flooding it with a thirty grain solution of gum arabic before dessication. To our surprise, however, this plate developed with less rapidity than an ordinary gum plate prepared without albumen, and on repeating the experiment in various ways we became, at length, quite convinced that the presence of the albumen had a positive action in retarding the development, although by allowing a longer time a dense negative could be obtained. Previous to this we had also noticed that plates prepared by Major Russell with a strong solution of meta-gelatine containing gallic acid did not develop as quickly as plates made with gum and gallic acid. We are therefore disposed to consider that the chemical nature of the organic preservative exercises an influence upon the rapidity with which the latent picture is rendered visible, and that this effect does not depend altogether upon the density of the preservative, or upon the extent to which it keeps open the pores of the collodion film.

"COMPOSITION" versus "PATCHWORK."

By A. H. Wall.

Unlike sundry editors who hope to make their own lights shine before men with greater effect by popping an extinguisher over every minor wick, the editorship of The British Journal of Photography has been characterised by the greatest liberality, and opinions the most antagonistic to the Editor's have found frequent expression in pages from which a word of his could exclude them. I am therefore encouraged to send, for insertion, a few words upon the subject of "composition printing," as some term it, or what our worthy acquaintance, "Mrs. Spriggins," calls "patchwork." Believing that these "composition" prints show the most palpable signs of non-composibility, I incline to the latter definition, and, with your permission, will tell "the reason why."

In reference to some of the Editor's observations upon this subject, he will pardon me for adding that I think he has somewhat mistaken the drift of Mr. Hannaford's remarks, and the intention apparent in the epistle of our amusing friend, "Mrs. Spriggins." The gentleman denounced the practice of calling a bank a mountain, and the stream of water from a print-washing machine a river; and the lady ridiculed pretensions to artistic qualities based upon no better foundation than that of patchwork. I am also inclined to think that you have mistaken deception for imitation, which is a widely different thing. I would not willingly disparage the productions of such talented men as Robinson and Rejlander, both of whom I greatly respect; but it is time that photography should take higher ground than it has hitherto done, and make its claims to the artistic known and respected in a sphere from which it is as yet excluded. To show that the art is *capable* of effecting such an advance as I contemplate would be apart from my present purpose, but this may be done easily.

If the intention of our "patchwork" printers is deception, in the sense of making one thing look like another, they fail most signally — the only deception attained being that for which their beautiful art suffers to a very serious extent. This deception (which I most earnestly denounce) is that which substitutes things unreal for others which they are palpably unlike, and so brings photography (an art which has its highest and *only* value in its wondrous truthfulness) into disrepute. Take away *this* good name, and it is "*poor indeed!*" Of course I admit, with Horace, that "fiction to please must wear the garb of truth," but this is no argument for cutting "the garb of truth" to the fashion of fiction.

Now it is, I think, clearly impossible that the most talented and skilful photographer can, *with a pair of scissors*, approach the appearance of that imperceptible boundary of vision which, for want of a better term, we call the outline — a thing which the painter, *with all his power of mechanically softening one colour or shade into another*, finds most seriously difficult of imitation. I appeal to all who have ever touched a pencil under the eye of a competent instructor or the guidance of a cultivated taste to bear me out in my assertion. In an artist's mind the sweetest charm possessed by a really good photograph lies in the very quality these barbarous wielders of the scissors would so ruthlessly and thoroughly destroy. Upon my word, this cruel cutting is, in my opinion, downright sacrilege, substituting as it does the hardest, sharpest, and ugliest of outlines for that exquisitely softened and melting boundary which we only meet with in nature and in photographs.

Again, to take another view of the matter: although it is true that artists compose a single statue from the selected beauties of many figures—that the landscape painter will produce a picture from no better model than a little earth with a few sticks and stones—the portrait painter the head of a beautiful young female from that of an ugly old male model—or that another will draw an earthquake from a load of coals shot down on his studio floor; still the first does not *literally* model the extremities of this figure and take the *fac-simile* head of that to be simply stuck upon the literally-copied body of a third, but artfully combines the whole into the appearance of one by the exercise of his anatomical and artistic knowledge and *imagination.* And the others are only dependent upon such miscalled models for originating in their minds the real subjects from which their pictures are produced.

The imitation therefore of such lofty flights being so perfectly unjustifiable, such ridicule as may be found in your own and contemporaries' pages, more especially in publications connected with or devoted to art, must naturally be expected. Who can soar after the birds of nature with wings constructed by the aid of scissors and paste without ludicrously tumbling to the ground? I do not look upon the greatest ingenuity or skill as at all palliative of the practice—the more artfully concealed the more mischievous the result, because the thing is then more likely to be looked upon by the uninitiated as genuine, when the art itself suffers; and an operator who displays such capabilities ought to know better, or, knowing better, he sins against his conscience. I know there are many who have never before viewed the matter in this light —who looked upon photographs as photographs merely, and pictures as pictures, without contemplating the possible connexion of the two, and who therefore wink at that in a photograph which they would at once denounce in a drawing; but it is not to the advantage of photography that this is so.

The composition of *genre* pieces does not necessarily imply the cutting out and patching which I venture to condemn; and most decidedly do I decline subscribing to the opinion that the only "difference between composing a subject and taking it on one plate, and taking portions of the subject on separate plates and combining them subsequently," is "that the latter is the more troublesome method, and produces *better* results." A good enlarging process, and a lens commanding a wide angle of view, with clever models, and judiciously chosen accessories, are the right tools for photographic composition pieces, *but not the scissors and paste pot!*

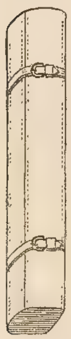
Photography's legitimate mission is, truly, a great and glorious one. As a scientific agent its aid is already acknowledged to be invaluable; and in all such branches of the fine arts as, strictly speaking, are imitative, it may yet take a most honourable and distinguished position. Although I use the word imitative in its strictest sense, I believe that most of the qualities claimed as "imaginative" belong clearly to imitation; for there is that poetry and beauty in nature which, whether transcribed by brush or camera, will be found in pictures in exact ratio with their truthfulness. It would lengthen a communication which is already too long to define this more thoroughly, so I at once conclude.

MOGINIE'S NEW PORTABLE TENT.

As the season has now fairly set in when photographers may be expected to take the field, and having devoted some amount of space and attention to those who follow the dry processes, we consider that the advocates of moist collodion have now a full claim to some notice. We therefore purpose describing a new portable tent for field work, which has lately been devised by Mr. Moginie, and which he has submitted to our inspection.

One of the principal objections to most of the tents already in use consists in their occupying too much time in erecting, and another in the trouble mostly experienced in getting the covering properly over the framework. Again, loose pieces are a fruitful source of disaster, either from being lost or mislaid, to say nothing of not unfrequently misfitting, in consequence of one piece being accidentally substituted for another. In the arrangement, of which we give a cut, these sources of discomfort have been provided against, the framework, cover, and stand being constructed of but few parts and no loose pieces, and a fair amount of rigidity attained by judicious triangulation of the component portions. It can be readily and rapidly erected, having been unpacked and put up in our presence in less than a couple of minutes; and by aid of four pegs and cords, which are permanently attached to the uprights, a sufficient resistance to wind is secured, provided that it be not such a gale as one during which no photographer would dream of operating.

FIG. 2.



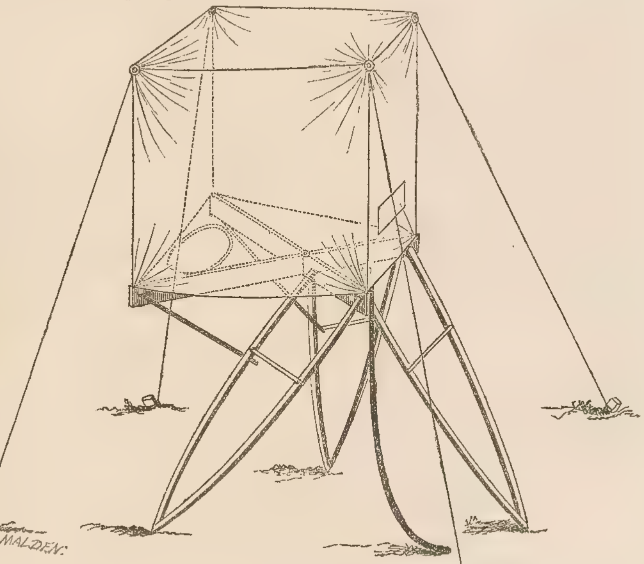


FIG. 1.

The cross-like base of the chamber, when not in use, folds quite flat, and, with the legs of the tripod and other paraphernalia, can be made into a very moderate-sized bundle (as in Fig. 2) for transport, and, as we are informed, weighs but twelve pounds—a weight considerably less than many cameras with two or three dark plate frames. The uprights of the dark chamber are contained within it, permanently attached to the several angles, and the extremities of the uprights fit into sockets at the points of the cross-piece at the base, consequently the mere act of putting up the supports also erects the tent itself. One triangular segment of the bottom of the chamber has an aperture, with elastic band, through which the operator gains admittance for the upper part of his body, light being excluded by its fitting closely round the waist. The opposite triangular segment forms a sink for the washings: it is lined with caoutchouc, and has a flexible tube to carry off the slop, &c. The working space is rather more than a yard square, but can of course be made almost of any desired size, and various conveniences are provided for suspending a small cistern for water, supporting the nitrate bath, camera frames, bottles for chemicals, and all other requisites, while an arrangement to secure ventilation without admitting light has also been attended to. All the other details are so readily gathered from mere inspection of the illustration that it is needless to particularise them further. We believe that these tents are to be seen at the establishment of several dealers in apparatus, which will no doubt be notified in advertisements.

ON THE RELATIVE SULPHURISING TENDENCY OF NEW AND OLD HYPO. BATHS.

By C. Oakeshot.

[Read at a Meeting of the North London Photographic Association, May 30, 1860.]

The following experiments, undertaken with a view of finding whether the hypo. bath by use acquires any increased tendency to sulphurisation, may, perhaps, be not altogether without interest. I give them for what they are worth, leaving it to photographers generally to consider if they have any practical bearing on the subject of a proper fixation of their prints.

A new bath was mixed—

Hyposulphite of soda ...... 2 ounces avoirdupois.
Ordinary water ....12 „ fluid.

About as many prints on albumenised paper as would be equal to half a sheet were fixed in this bath. A portion of the bath was then poured into two wine glasses, and common salt added to one. A small silver coin was placed in each glass; the glasses were removed into the strong light of the operating-room, and left there undisturbed for twenty-four hours, by which time both coins were sulphurised to a buff tint, the one in the glass containing salt being deepest in colour. The remainder of the bath was then used to fix two more batches of prints, and again tried in the same manner; but, instead of salt, some kaolin was stirred with the solution in one of the glasses. The kaolin quickly restored the hypo. to its originally clear and colourless condition. Coins left in these solutions for twenty-four hours were sulphurised to a deep brown, or rather a black tint—the one from the solution containing kaolin being deepest. A portion of a new and unused bath was then tried: the coin after remaining in this for twenty-four hours became tinted to a buff, somewhat less deep than those which had been tried in the bath used once only.

These experiments were made with ordinary materials. The hypo. was dissolved in hard water, and no care was taken to have the coins chemically clean, and therefore it was not improbable that some organic matter might be adherent to their surfaces, and influence the result. I thought it advisable to repeat the experiments with greater precautions.

Five small silver coins were left for some time in dilute nitric acid, then well washed and polished with a clean cloth.

A bath was made—

Hyposulphite of soda .... 2 ounces.
Distilled water ....12 ounces.

A portion of this was tried unused, a second portion after it had fixed one lot of prints, and a third after it had been used three times. The cleaned coins were left in these solutions for twenty four hours.

RESULTS.

Bath unused—Coins became very faintly tinted.
Once used—
1st, with salt added ....tinted to a pale buff.
2nd, without salt...............same, but lighter.
Used three times—
1st, with kaolin added...........to a decided buff.
2nd, without kaolin ....not quite so deep.

The next object was to see whether light materially assisted the sulphurisation. A portion of a bath which had been used for fixing three batches of prints was placed in a dark part of the dark room, and a shilling, well cleaned, left in it for twenty-four hours. When removed it had acquired a deep bronze colour, visibly less dark than the one which had been treated the same way but left in the light: this bath was made with ordinary water.

From these experiments I infer—1. That the hypo. bath made with distilled water becomes less discoloured by use, and also has not so ready a tendency to sulphurise as one made with ordinary water. 2. That the bath, whether made with distilled or with ordinary water, by repeated use, acquires an increasing facility of sulphurising; and, 3. That, as light appears to assist this tendency

it may perhaps be well, while the prints are in the hypo., to guard against their being exposed unnecessarily to the light.

Mr. Hardwich's experiments, in reference to the assertions of of MM. Davanne and Girard, were repeated. Thirty grains nitrate of silver were converted into chloride, and dissolved in hypo.: it required exactly fifty-three grains to take up every particle of chloride. Crystals began to form in twenty-four hours. The solution was left undisturbed for three weeks, when the bottom of the glass containing it was covered with the crystals; the supernatant liquid was then poured off into a large watch class, and placed in the light; a black scum soon formed on the surface of the liquid, and a black deposit of, I suppose, sulphide of silver began to settle to the bottom of the glass. A shilling was now dropped in and left there for twenty-four hours: it remained there for that time *without showing the slightest symptom of discolouration from sulphur*, although from the increasing black deposit it was plain the liquid was undergoing decomposition. No further crystals formed till the liquid had nearly evaporated, and when nearly dry, two or three bunches of crystals were seen on different sides of the glass *altogether different in shape* to those which had before formed. The crystals first removed when dried weighed exactly thirty grains. It took just twenty-five grains hypo. to dissolve five grains of these crystals.

My next attempt was to find the minimum of time a print might be left in the hypo. bath, in order to be properly fixed. Five portraits were vignetted. The reason for vignetting them was that the large surface of white would more readily show any trace of yellowness they might acquire in the after treatment. These prints were all toned in a gold bath, very slightly alkaline, to which was added a few grains of nitrate of soda (the latter salt appears to make the print tone more rapidly, and with greater certainty). They were fixed in a new hypo. bath, of the strength before given, made with hard water. Each print was placed in this bath separately, and the solution agitated while they were being immersed, and for three minutes afterwards.

1st	was left in	3	minutes only.
2nd	„	5	„
3rd	„	7	„
4th	„	10	„
5th	„	15	„

They were then washed in running water for sixteen hours, and when dry were all perfectly clear in the white parts; not the slightest indication of yellowness in either of them. They were then treated separately, with two pourings of boiling water.

RESULTS.

No. 1......	3	minutes in hypo	.......very yellow.	
„ 2......	5	„	...... „	but less.
„ 3......	7	„	...... „	„
„ 4......	10	„	.. ...nearly white.	
„ 5......	15	„	......quite white.	

Another bath was made with distilled water, and five more vignetted prints fixed in it. These were all cut from the same sheet of paper, but the shortest time of immersion was seven minutes.

RESULTS.

No. 1......	7	minutes in hypo	.......slightly yellow.
„ 2......	10	„	...... „
„ 3......	15	„	......quite white.
„ *4......	20	„	...... „
„ 5... ..	25	„	......a faint rendering to yellowness, very slight.

From this it appears that the time usually recommended for the prints being in the hypo., fifteen minutes, is a safe one, though they seem to suffer little injury from being left in nearly twice as long. I forward all the prints. You will observe that most of them are more or less covered with brown spots: these are owing to blisters of the albumen surface, which formed when in the toning bath.

I incline to think that any sample of paper which blisters, either in the toning or fixing bath, will be imperfectly fixed, and sooner or later must surely show indications of these brown spots. The hypo. appears to be retained between the albumen and the paper with particular tenacity, which no amount of washing will effectually remove. I have noticed the same occur with the collodio-albumen plates; those which blistered invariably showed the same kind of spots, even after the plate had been well varnished. The blisters in the paper may perhaps arise from the habit which some makers have of passing the paper, after being albumenised, through rollers, in order to give it a smooth and finished appearance.

* This was not treated with boiling water.

The paper used in these experiments was La Rue's, obtained from one of the largest London advertising houses, and unfortunately was a very indifferent sample.

I had purposed carrying out my experiments still further by fixing vignetted prints in old or rather many-times-used baths, and treating them with boiling water; but, being professionally engaged, as yet I have not been able to spare the time.

I know of no means for dissolving hypo. left in the paper which answers better than boiling water, and shall be greatly obliged if any one will point out one more delicate and certain.

I have omitted to mention that the temperature of the room at the time the prints were fixed was 65°. The hypo. bath had been mixed fully six hours before being used.

I wish further to observe, with reference to the experiments with the silver coins, that because they were deeply sulphurised after being left in the hypo. for twenty-four hours, it does not necessarily follow that the same result will happen with prints which remain in the fixing bath only a quarter of an hour; but it must be borne in mind that the deposit on the paper, from its finely divided condition, and also from the permeability of the paper allowing the hypo. to come readily in contact with every particle, may perhaps be placed in a condition to be more easily acted upon. The object was to see whether the hypo., after use, retained its original condition, or whether it acquired any greatly increased disposition to part with its sulphur. I think the experiments go to prove the latter.

ON PHOTOGRAPHY AND ITS APPLICATION TO MILITARY PURPOSES.*

By Captain Donelly, R.E.

Captain Donelly wished to guard against the supposition that might arise from the title of his paper, that he proposed to bring forward any new or remarkable application of photography to military purposes. He did not come forward as an inventor. It was not his intention to propose to defeat armies, destroy fleets, or take fortresses by the aid of nitrate of silver and the camera obscura. But he would endeavour to explain, as clearly as he could, the general principles of photography—an art which was everyday rapidly extending, and the aid of which might, he believed, be usefully enlisted in many secondary military operations.

Captain Donelly then went into a lucid detail of the scientific principles upon which the art of photography rests, occasionally illustrating his theories by experiments. One of his experiments was strikingly beautiful. In exemplifying the action of light in effecting chemical changes and combinations in certain substances, the lecturer placed a mixture of hydrogen and chlorine, contained in a glass bulb about half an inch in diameter, before the intense white light produced by burning phosphorous in oxygen gas. With this kind of light no perceptible action upon the mixture in the bulb was produced, although, as the lecturer stated, the action of the sun's rays would have instantly caused the gases to combine with explosive violence. The bulb was then exposed to the influence of the intensely bright blue flame produced by the combustion of a mixture of the vapour of bisulphide of carbon in binoxide of nitrogen, which, though only burning for a fraction of a second, caused the mixture of hydrogen and chlorine instantly to combine chemically with such energy as to burst the bulb with a sharp report, in consequence of its containing a larger portion of the violet rays of the spectrum than the light previously employed.

We have seen this experiment performed in other ways, but never more successfully. Professor Roscoe lately, at the Royal Institution, procured the combination of the mixture of hydrogen and chlorine, by burning phosphorous in oxygen, contained in a *blue glass* globe; and we mention this as conclusive evidence that the union is effected by the chemical or violet rays, as the Professor could not succeed in exploding a bulb when he employed a white or red glass globe. We have not space for Captain Donelly's very clear enunciation of the principles of the art, as they have been frequently explained in the pages of this Journal, and as they may be studied in the published handbooks upon photography, such as Hardwich's, to which Captain Donelly especially referred his audience.

The lecturer then said, with reference to the application of photography to military purposes, the first necessary was portability in the apparatus. Captain Fowke, of the Royal Engineers, who had fitted out most of the parties of engineers who had taken photographic apparatus with them, invented a form of camera which was extremely portable, and could be carried in a knapsack. Captain Donelly ex-

* A lecture delivered at the United Service Institution, London, on Friday, June 8, 1860.

hibited the camera, and explained its folding arrangements; that, with the chemical boxes, was carried on pack saddles. Numerous photographs had been taken by parties of sappers, many of which Captain Donelly exhibited. Among them were some by Corporal Lawson, who was with Captains Gordon and James, on the Asiatic boundary, surveying in Asia Minor, between Russia and Turkey. Others by Sergeant Church, who accompanied Colonel Stanton, when he went to verify the reports on the projected line of railway across the Isthmus of Panama—the Honduras line. Some were taken in India, at Singapore, and others, executed in China, furnished Mr. Burford with the materials for his panorama. Some were taken by Sergeant Mack, at Moscow, when he accompanied Lord Granville. Two were taken at Varna, and, unfortunately, the photographers who went out to the Crimea were lost on board the "Prince." One photograph exhibited the plan of the ships in the order of landing the troops. Hence they saw that photography could be applied under very difficult circumstances, such as on long and rapid journeys.

The men of the Engineer's corps were taught the art, and specimens of their productions were on the table. Many of the photographs, Captain Donelly remarked, were not such as Mr. Fenton or Mr. Thurston Thompson would care to exhibit at the photographic exhibition; still some of them were very good, and all of them very creditable, when the circumstances were considered under which they were taken. Photographs of a country gave a most truthful and accurate idea of it. They would do more to give an accurate idea of any particular position than yards of description on foolscap. They might be found of great service in illustrating a report on a country—and, indeed, they had been so employed by Colonel Stanton—and in that way they might be of great service to the general commanding an army in the field, as also in copying and multiplying plans, as in the case of the plan of the position of the ships for landing the troops in the Crimea. Captain Donelly also exhibited a number of photographs taken at Chatham, showing the admirable means which they afforded of conveying descriptions of various military operations, such as bridge making, &c., so giving a perfect idea of a place. Photographs were of great service in supplying engineers with ready and rapid means of showing the state of works on any particular day. Captain Donelly exhibited a progress plan of the works at Aldershott which was done by the War Department, by which it could be seen at once how far the works had proceeded, which could only otherwise be done by expensive lithographs, and then not so well or so rapidly. They were enabled to obtain a picture of any size they wished; and Captain Donelly said that he could not give a better example of that than by referring to five photographs of one of the Cartoons in Hampton Court *(Elymas the Sorcerer Struck with Blindness)*, the photographs being of the respective sizes of 8 by 5, 15 by 11, 23 by 15, 31 by 21, and 48 by 30 inches. It might be said that these had little to do with the application of photography to military purposes. Captain Donelly exhibited them as admirable specimens of photography executed, with the assistance of men of the Royal Engineers, by Mr. Thurston Thompson, who had instructed most of the men at the South Kensington Museum. Captain Donelly called attention to some specimens of photographic reductions of the maps of the Ordnance Survey from one scale to another for engraving. By employing photography for these reductions the Survey Office at Southampton saved £1600 per annum, and the whole saving of the survey would be about £32,000, this saving being accompanied by increased rapidity and accuracy in the reductions. Formerly the reductions were made by the pentagraph, the operation being long and tedious, in which, as the hand and the eyes were employed, the accuracy was dependent, to a great extent, on the skill of the operator. Now, by merely fixing the camera at different distances from the plan to be copied, it could be reduced to any scale desired by an operation in a few minutes, and with the greatest accuracy.

The scales of the maps were for—

Towns............	$\frac{1}{500}$ or 10.56	feet	to 1 mile.
Parishes	$\frac{1}{2500}$ or 25.344	inches	„
Counties	6	„	„
Kingdom	1	„	„

The ten feet scale was reduced to the twenty-five inches, and the twenty-five inches to the six inches. But by further reduction the perfect truthfulness of photography rather militated against it. In reducing from the six to the one inch scale the photograph was too crowded with details, so that at present in a portion of that operation the pentagraph had still to be employed.

The photographs were at once transferred to the copperplates for the engraver, or the zinc plate for the zincograph process, by the following means:—Printer's tracing paper was employed, the paper being sensitised by being washed over with a saturated solution of bichromate of potash and gum water. That prepared paper was exposed to light under an ordinary glass negative, and the portion of bichromate of potash acted on became insoluble in water (that being a peculiar property of bichromate of potash). The print was then placed, face downwards, on a metal plate, covered with the greasy lithographic ink, and passed through a press until it became almost black in appearance. It was then washed with a solution of gum arabic and hot water, and brushed with a camel's hair brush, which removed the portions not acted upon, thus leaving a print in light brown colour in lithographic ink. That could be either transferred to the copperplate, as a guide to the engraver, by burnishing, or it might in the same way be transferred to the zinc plate, and printed from immediately, without any further process, by simply being inked.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

NOTICE TO MEMBERS.

The *soirée* to be held on the occasion of this Society's Anniversary Meeting, on the 21st instant, at St. Peter's School Rooms, Walworth Road, will commence at *seven o'clock precisely*, when the annual report will be brought forward; after the reading of which the members will proceed to elect officers for the ensuing year, and elect new members. Gentlemen desirous of being nominated for election as office-bearers will please to forward their names to the present Secretary, Mr. Wall, 90, Cannon Street West, City.

Several gentlemen residing in the country having sent their names (and addresses) for election as members, others similarly situated may be glad to know that this Journal, as the Society's recognised organ, will be forwarded, post free, to all such members, and that any distribution of photographs which may be made during the next year will not be performed without due recognition of their rights. Communications from provincial members of this Society will be brought forward for discussion, &c., at the usual meetings; and, in short, it is expected that this arrangement may be made the medium of many little interchanges of services mutually advantageous to all concerned.

ALFRED H. WALL, *Hon. Sec.*

EXCHANGE CLUB,

(In connexion with the South London Photographic Society).

The first exchange of photographs will take place early in July, and those desirous of becoming members in time to avail themselves thereof are requested to intimate the same to me during the current month, forwarding prints, unmounted, offered for exchange (together with one copy of each as a contribution to the Society's portfolio), with a notification as to the class of photographs desired in return.

Each member should send stamps sufficient to cover all postage in his individual case.

MICHAEL HANNAFORD, *Hon. Sec.*

6, *South Grove West, Mildmay Park,*
Stoke Newington, N.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

An ordinary general meeting of this Society was held on Tuesday, the 5th instant,—P. Le Neve Foster, Esq., V.P., in the chair.

The Secretary read a letter from Mr. Denyer, photographic artist, of St. Petersburgh.

The object of the letter was to make the writer known in this country, and expressive of a desire to become an honorary member of the Photographic Society. It was accompanied by two *very* large portraits, artistically executed, but possessing all the defects inherent in specimens taken by lenses of very large aperture, viz., want of distinctness and atmosphere, the figures appearing flattened. In point of execution, apart from the defects produced by the lens, the proofs were all that could be desired. A vote of thanks was awarded to Mr. Denyer.

The Secretary read a letter from Capt. Biggs, of the Bombay Artillery. Four large-sized photographs of Indian subjects, from the neighbourhood of Bombay, upon plain paper, printed by the ammonio-nitrate of silver process, accompanied the letter. They were very clean and good. They were from paper negatives by the original Talbotype process, taken upon Turner's paper. The proofs were printed upon Marion's positive paper.

The letter related chiefly to the difficulties experienced by photographers in the Bombay Presidency, partly from the nature of the climate—the foliage never being in repose, necessitating the exposure being made before the breeze sets in, which is usually about nine A.M.—and partly from the enormous extra cost of chemicals, and their inferiority to English chemicals, the cost being three to four hundred per cent. higher. The thanks of the Society were voted to Capt. Biggs.

Mr. Dallmeyer then read a paper *On Distortion as Produced by the Existing Forms of View Lenses, &c.*, which we do not insert for reasons elsewhere given.

Mr. Malone asked how many surfaces there were in the altered portrait lens.

Mr. Dallmeyer, in reply, said six.

Mr. Shadbolt asked what was the *equivalent* focal length.

Mr. Dallmeyer said about twelve inches, being about the same as those supplied by his late father-in-law for the last four years. The aperture of the front combination was three and a quarter inches, and that of the back combination three and a-half inches, which gave great equality of illumination over the whole extent of plate, otherwise there was no material difference in time of exposure. He said that he had not adopted the most elegant manner of proving his position, but had availed himself of a familiar means of illustrating the angles of distortion. He stated that the form of the front combination, as left by his late father-in-law, did not admit of its being used as a single combination. He (Mr. Dallmeyer) had so constructed the front combination of *his* portrait lens, that on removing entirely the back combination this might be screwed into its place, and then be employed as an ordinary view lens.

The Chairman having invited discussion,

Mr. Shadbolt said he was not a little disappointed in finding a total absence of novelty in that which was brought forward as such, inasmuch as he had in his possession a lens, made by the late Mr. Archer, that comprised nearly all, if not absolutely all, the principles involved in the one described by Mr. Dallmeyer. His memory was bad as to dates, but he could vouch for his possession of this lens for upwards of seven years, but whether he had possessed it eight or nine years he could not recollect. He had resided in the house which he now occupied for seven years on the 3rd of last March, and he took Mr. Archer's lens into the house when he first went to it, consequently he was clear upon that point. The front lens fitted the back of the mounting, and was the lens which he commonly uses as a landscape lens, and a better landscape lens he had never yet seen of any one's manufacture. As a double combination lens it was constructed according to the ordinary form, after the formula of Professor Petzval, the late Mr. Ross, and the present Mr. Ross—that is to say, the front being a cemented compound, and the back being a separated compound; but, in addition to that, the diaphragms were placed between the lenses at a distance corresponding to the respective foci of the combinations of the lenses, that is, being somewhat nearer to the front lens, which was of shorter focus than the back, and it is the position of the diaphragm which avoids the production of distortion, and the introduction of a small concave at that spot which, he conceived, lengthened out the focus, precisely in the manner Mr. Dallmeyer had described. Now that was an addition to the arrangement which was made subsequently to the construction of the lens. It was not added by Mr. Archer but by himself, from hints given to him by Mr. Archer; and he could vouch for the fact of those hints having been given to him five years ago, if not six. Mr. Archer was then using, for landscape work, a lens constructed precisely similar to the one he (Mr. Shadbolt) was then using. Mr. Archer showed him that lens; and one particular point in connexion with its use was the advantages he found in taking interiors where crowded for space and wishing to get a considerable angle. But he thought Mr. Dallmeyer had a little slurred over the fact, that in order to get freedom from distortion he must sacrifice something—possibly a certain portion of flatness of field. He had not described the mode in which he had altered the ordinary portrait lens, but, from what he had stated, he presumed Mr. Dallmeyer used a back and front combination of identical focus, with a concave lens between them; in point of fact, taking up just what Mr. Sutton had alleged as being his symmetrical triplet. At the time when that triplet was brought forward, he (Mr. Shadbolt) pointed out the facts to which he was now alluding, and consequently alleged that there was not the novelty that was supposed to exist in the lens. He was not aware that Mr. Archer did very publicly bring forward that lens, but that he made and sold several of them he did know, both from Mr. Archer himself and from his late wife. He (Mr. Shadbolt) saw several of them in his possession at the time that he first of all showed him the mode in which he (Mr. Archer) was then working. Not being aware of any public statement of the fact by Mr. Archer, it is probable that neither Mr. Sutton nor Mr. Dallmeyer had heard of it; but certainly at the time that Herr Paul Pretsch introduced Petzval's orthographic lens he (Mr. Shadbolt) did publish a statement to that effect. He believed that about two years ago—certainly eighteen months ago—he pointed it out, and, subsequently, when the so-called Lens-Committee of the Scotch Society issued a very droll report upon lenses, he pointed out the fact that they assumed to have discovered something extraordinary—that the position of the diaphragm in front of a lens produced the barrel-shaped image, and the diaphragm, when placed behind, produced the hourglass shaped image of a square original. That was not novel to him, and he did not presume that it was novel to many others; yet still that fact was pointed out at both the times specified. It had been frequently remarked, that in optical instruments they very rarely could get an advance in one direction without a sacrifice in another. If Mr. Dallmeyer could assure the Society that the alteration which he had made in the portrait lens did not sacrifice anything, either in definition or curvature of field, then he presumed Mr. Dallmeyer's must be considered as an advance in the construction of the lens. Unless Mr. Dallmeyer could show that he had sacrificed nothing, he was afraid they were where they were before, except that they were simply substituting one error for another. He (Mr. Shadbolt) stated his object to be for no other purpose than simply to draw as much out of Mr. Dallmeyer for public information as could possibly be obtained.

Mr. Malone confessed his ignorance of the exact proofs of the theory of optics. Of course he should not pretend to enter into any philosophical discussion of the subject. He regretted there were not more gentlemen of Mr. Shadbolt's degree of attainments. He (Mr. Malone) thought he might be allowed to mention that it had always been a great object with him that the late Mr. Ross should have been attached to the Society in a permanent manner. His suggestion was overruled, and it was said that he was so connected with trade that it would not be well to place him on the council. He regretted that sort of feeling to this day. He could not, of course, but welcome Mr. Dallmeyer's presence at the meeting. Mr. Malone then stated that, having made these introductory remarks, he must say that it certainly was very clear, as Mr. Dallmeyer had said, that photographers generally, not having that intimate knowledge of this subject to enable them to know sufficiently what to expect from a lens, it was only by trying it that they got any idea at all about it other than that which they got from the makers and sellers of lenses, and that which was occasionally written upon the subject. They were much perplexed. They knew that it was the business of the maker of the lens to make the best of his invention. In trying to disparage a lens, care must be taken that it be done with judgment; and, without taking upon himself to be a general censor, he would just point out how it appeared to him members occasionally erred. The late Mr. Ross had a strong opinion, speaking generally, that those writers and gentlemen who took part in optical discussions had what is called the school knowledge, which might be sufficient to enable them to take some part in a discussion, and to understand the nature of improvements suggested, but hardly justified them in giving to an optician in full detail the plan of procedure by which he should make a good lens of new form. Now this was the case: they had a suggestion made by a person only partially competent; and then they wanted such a practical man as Mr. Ross or Mr. Dallmeyer to work it out for them, which, of course, they did not want to do, for it involved a great amount of labour—ideas coming fast, they had all the past to correct. In addressing himself to the subject as a photographer, and speaking as a practical photographer who had handled many lenses, his impression was that members ought to hail and welcome cordially any attempt to produce a lens that will give straighter lines—if without loss of flatness of field or definition so much the better. Let them take any invention offered to them, and look well, calmly, and dispassionately to see whether there were any advantages of which they could avail themselves. He hailed with joy the introduction of the orthographic lens, and he had expected to get better results than he found, for they had been told it gave straight lines. Now there was a fallacy involved in that. For instance, if a picture with a gateway were examined, the lines of the gateway would appear to be straight, because they did not fill the whole of the picture. But the lines were not straight: it was only a kind of artifice. There was no doubt that the orthographic or orthoscopic lens would be a better lens than the old form of view lens, but it was seen at once that there were many things to discriminate. They found that in taking a view of a street with the corner of another street running into the picture, then that corner would represent that line curved; and if that corner of the street ran into the whole picture, they would, by the orthographic lens, have the buildings appear to be about to tumble over into the street, or to tumble out at the bottom—in neither of which cases would it be natural—and then they would probably prefer the old form of view lens. Photographers could not get rid of the necessity for the old form of view lens; and it appeared to him that, on starting, they must take the old form of view lens, whether single or double, which gave the barrel-shaped distortion, or the orthographic, which gave the pincushion shape; and, if all that had been said at the meeting were true, they would have to add this third lens. Mr. Dallmeyer had said that his portrait lens, in which he had lessened the distortion, might be taken in half, and one half used as a view lens. The reason he gave for that did not satisfy him (Mr. Malone). Mr. Dallmeyer had said that, in dealing with buildings with a view lens, they got that barrel-shaped distortion; but he said, if they took a landscape in which there were no buildings, then that distortion was of no consequence. He thought it was of essential importance, and he would give an instance where it would be detected. If this single combination were taken to avoid any loss by diffraction in consequence of the number of reflecting surfaces, or want of flatness of field, and a picture were taken containing trees, which in nature were absolutely straight, and it was wished to produce them in the picture as they absolutely appeared, then they must go back to the old lens, and have the trees of a barrelled shape. He knew it would be said, Who knew that they were barrelled? He wanted photographers to guard against that. Let members look at the three diagrams and say which they would prefer. He (Mr. Malone) thought they must sacrifice a little definition if they could get straight lines. The result is that photographers will find all these lenses useful, and perhaps a fourth, for he was bold enough to think that they ought to have a very large double portrait combination for certain purposes, to meet every possible case, and to do the best under any circumstances.

Mr. Bedford said certainly the objections that Mr. Malone made to the peculiarity of these lenses prevailed to a great degree. He (Mr. Bedford) had had a sea line curved up and down, he had had larch trees and fir trees bent in all ways, and he thought it was necessary, in order to be prepared for all kinds of work, to take all the lenses that are made. He (Mr. Bedford) took a portrait lens of Ross's—the one known as the £25 lens—which he found very useful for dark subjects, in glens and interiors, and

such subjects as those; the orthographic for flat architectural views; and the old Ross view lens—than which there was nothing better—for landscapes, as giving greater depth of view and better average perfection than any other lens. He (Mr. Bedford) was quite certain that the orthographic was not an improvement for landscapes, although very useful and almost indispensable in certain exceptional cases. He should have liked to have seen specimens of productions of Mr. Dallmeyer's lens upon larger plates. The lines seemed straight, but even in that small surface there was a very sensible falling off in the sharpness of the picture, and particularly that of *The Times:* small as it was the outside lines were not only out of focus but blurred. He did not know what the lens had been when worked under all its advantages.

Mr. Hardwich said he had lately been attempting to copy maps and pictures of a large size, and had been struck with the necessity of not too much lessening the aperture of the lens. He took an interest in the symmetrical triplet lens, or in any lens which promised an image free from distortion, and he would wish to inquire what the chances were of getting such a lens to cover a plate two feet square, and to work within a reasonable time? Would the number of reflecting surfaces be so great as to occasion a serious difficulty in producing intensity? He supposed that it was in copying maps particularly that the triplet would be used. Could it be so used without cutting off too much light? He would also ask of gentlemen who had used Petzval's orthoscopic or orthographic lens on very large plates, how far the distortion became a serious matter? because only the day of the meeting he had been measuring very carefully on a plate twenty-two inches square, by fastening strings across a board, and taking the exact distances between those strings. Unfortunately he was prevented finishing his experiments, but when he came away he had not succeeded in satisfying himself that there was any material distortion. He (Mr. Hardwich) remembered a conversation he had with the late Mr. Howlett at the time the orthoscopic was first made, and that gentleman said the error was so small that he might practically disregard it: whereas with his old form of lens, the lines of a map taken piecemeal would not meet, with his orthoscopic the lines did meet. The result of much that he had since heard was different. He confessed, from his experiment, he was astonished to find how small was the distortion. The focal length of his lens was four feet two inches. He had been engaged in trying to find an easy method of getting up the intensity of negatives taken with long focus lenses. What he wished to do was to get rid of the bichloride of mercury. He believed they ought to discard the use of bichloride of mercury, for it was deleterious in its results, and, from what he had read lately, he believed it was difficult to get it off the plate again. He hoped that the optical part of the question was not concluded, for there were many readers of the Journal who wished for all the information it could give.

Mr. Malone thought it would not be out of place if he rose again to speak of an experiment which was pertinent to Mr. Hardwich's inquiry. He made the experiment in conjunction with Mr. Ronalds, the director of the Kew Observatory, and assisted him in carrying out the photographic registration there. Mr. Ronalds was extremely anxious to know whether he could rely upon photographic results as to division and so on. There was a certain normal line, and it became very important to ascertain the power of lenses with regard to this. Mr. Ronalds drew a square foot on paper with square inches with the greatest accuracy, and asked him if he could copy that of the exact size with the spaces true. Many experiments were made, and at last he succeeded in making a copy, which he believed he retained now, of the exact size of the diagram—a foot square, divided into square inches, painted black and white. Mr. Ronalds measured the copy with square and rule, and expressed himself satisfied with the result. He was surprised at getting so exact a *fac-simile*. The lens was made by Mr. Slater: it was a lens to take large portraits, of some four or five inches aperture, and it could be used either as two lenses together or as one, or there was a third lens put in to shorten the focus. The third lens was a greenish glass, and very slow for portraits; but tried in that way, with a stop which he believed was an inch, he got that result, and his impression was that he could not have done it with any other form of lens. He added that the late Mr. Ross impressed upon him the necessity, when asking what sized plate a particular lens would cover, of explaining the object in view: thus, if about to copy a map, so that the lines should meet exactly, they ought to go to the expense of a large lens with a long focus, and the result would be that they would get a portion out of the centre of the field which would appear to be nearly a straight line, but that of course involved expense. He had great hopes of Mr. Dallmeyer's lens.

Mr. Dallmeyer said he would explain the reason of his bringing the paper forward. It was owing to the fact of his being continually asked what lens was free from distortion, which led him to conceive the subject was not sufficiently well understood by most photographers, and it was for those that he had written the paper. He had purposely abstained from giving formulæ, for what he could give might be found in the works on optics to which he had alluded; and gentlemen, on seeing formulæ in a paper, often made the remark, that not being mathematicians they did not interest them. He had, consequently, simply exhibited the diagram. With reference to novelty, *he claimed none.* The lens was free from distortion as far as that was obtainable, for he might state that no lens could be made to project an image on a flat screen absolutely free from distortion. The nearest approximation possible required the lens to be of the same diameter as the picture produced, which he had stated was too expensive a matter to consider. Hence it was necessary to ascertain how far he could approach to the production of an image which was free from distortion; and it was both by form and focal length of the combinations that the distortions due to the displacement of the lateral pencils, as occasioned by the first combination, were corrected by the opposite nature of the distortions of the second combination, as was exhibited in the diagram; but the remaining distortions, as occasioned by the difference of the focal lengths, so to speak, of the central and marginal pencils, when the image was required to be projected on a flat screen, would remain, and could not be corrected unless the flat screen be exchanged for a curved one. Therefore it was desirable to arrive at the nearest approximation; and it would be found that the distortion due to the difference of focal length of central and lateral pencils presented but a small fraction as compared to that occasioned by the difference of the refracting angles of the lens, as shown in the diagram; and therefore he had neglected that distortion, and merely paid attention to the distortions he had previously alluded to. He would correct a mistake: his lens, when employed for architectural views, did not consist of two positive combinations with a negative lens between them, but of *two positive combinations only;* the number of reflecting surfaces therefore was six and not eight, as in Mr. Shadbolt's combination, and as such it was employed for views. He had already stated that the number of reflecting surfaces in lenses, where of necessity a small aperture was employed, was a great objection on account of the loss of light; and hence persons have found that with the orthographic lens the time of exposure, as compared with the ordinary view lens, was greater—perhaps double. With regard to lenses for copying, it was readily understood from what he had stated that the amount of distortion depended on the focal length of the lens: the longer the focal length the less the amount of distortion. He would beg to say that, perhaps, what was considered by Mr. Hardwich to be a chemical difficulty, might perhaps be due to an optical deficiency, and due to aberration from *diffraction;* for, if the amount of confusion produced by this aberration were taken into account for a lens of long focal length with a very small diaphragm, it might be that the confusion spoken of by Mr. Hardwich was due to that. He just threw that out as a hint, perhaps, to be inquired into, so as not to be misled in the *rationale* which he might form of the subject. With regard to a number of lenses being requisite at different times, that was one of the reasons why he had made his portrait lens subservient to different purposes—not that he wished to say, use the front lens alone, since the focal length of the front combination was different to the focal length of the two when combined. There might be at times a desire to produce pictures of different sizes; hence he had utilised his front combination, so that it might be employed to that end. With regard to the observations of Mr. Shadbolt, and his inquiry whether other important qualities were sacrificed to the obtaining the one sought after, namely, freedom from distortion and flatness of field, he had brought with him the pictures exhibited, by which he thought he had afforded the best means of judging as to its merits as a portrait lens. He had given its equivalent focal length and diameter, which expressed its rapidity of action; and, in regard to any sacrifice being made to give the lens the properties described, he believed there was no sacrifice of material consequence. With regard to the exposure given in obtaining the views exhibited, that was written on each plate. In answer to the remarks made as to the copy of *The Times*, he ought to have stated, on placing it on the table, that it was taken with an aperture of one and a-half inches, which was at least three times larger than that always employed for copying purposes; consequently, the remarks did not fairly apply. He (Mr. Dallmeyer) would be happy to answer any further questions.

The Chairman, in tendering the thanks of the Society to Mr. Dallmeyer, stated that the subject was most interesting to photographers, although he feared that among photographers generally there were not many who had gone deeply into optics, for he had generally found that when optical subjects had been brought before the Society there were very few who rose to discuss them. He thought it would lead to improvement if photographers would give more attention to the study of optics. He wished the members a pleasant and a happy vacation, and adjourned the meeting until the first Tuesday in November next.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of the Association was held at Myddelton Hall, Islington, on Wednesday, the 30th ultimo,—George Shadbolt, Esq., Vice-President, in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. Hill called the attention of the meeting to two samples of thick glass which he had been using in the printing frame. One was of a cerulean blue, the other of the usual green tint, and contrary to the general opinion that the blue would not only allow printing to be performed more quickly, but permit better tones, he found the green exhibited a decided advantage, although it had been in use more than two years. He exhibited slips of paper demonstrating these facts.

Mr. Dawson observed that it was not generally supposed that blue glass allowed more rapid action than colourless glass, but was considered

preferable to that having a greenish tint, and colourless glass was found to change.

Mr. Barber said that colourless glass ought not to arrest any of the rays.

The Chairman reminded him that a solution of di-sulphate of quinine, though absolutely colourless, arrested the whole of the actinic rays.

Mr. Barber said that with the quinine solution, though colourless itself, a blue colour is seen on looking along the surface.

The Chairman assented, and pointed out that, according to the theory of Professor Stokes, the blue colour was owing to the previously invisible actinic rays being stopped by the quinine solution, and thus rendered visible.

Mr. T. A. Barber read a paper from Mr. Oakeshot, of Ryde, *On the Relative Sulphurising Tendency of New and Old Hypo. Baths.* [See page 177.]

Specimens in illustration of the paper were also exhibited.

The thanks of the meeting were given to Mr. Oakeshot for his interesting communication.

The Chairman said that, as Mr. George Dawson's paper would embrace the same subjects as those treated of by Mr. Oakeshot, he thought it better to call upon Mr. Dawson to read his paper, and take the discussion on both together.

Mr. George Dawson then read a paper *On the Mutual Reaction of Chloride of Silver and Hyposulphite of Soda, and an Inquiry into the Cause of the "Measly Spots" in Positive Proofs.* [See page 174.]

Specimens of the various products were exhibited by Mr. Dawson—viz., the solution of pure chloride of sodium from the hyposulphite of soda; hyposulphite of silver, pure and white, which had been kept for three weeks excluded from light, air, and moisture; also specimens of the same in several stages of decomposition, owing to the influence of one or more of the above-mentioned destructive agents. The curious crystalline compound, or probably agglomerated mixture, arising from the addition of chloride of silver, in bulk, to hyposulphite of soda, was submitted to the meeting, and some specimens of albumen (pieces of the white of an egg) which had been treated first with nitrate of silver and subsequently with hyposulphite of soda. These, on being cut transversely, were very instructive, clearly displaying the fact that the nitrate of silver penetrated to a much greater depth than the hyposulphite, showing several distinct strata of action between perfect removal of the silver salt, partial decomposition, and total inaction. One of the "measly" proofs sent by Mr. Barnett to the previous meeting was shown by Mr. Dawson, denuded of its surface, and showing the "measly" spots *in situ*.

At the conclusion of the paper, the thanks of the meeting were so warmly volunteered, that the Chairman remarked that it was manifestly unnecessary to put it to the vote whether they should be accorded. He thought the papers just read would afford ample discussion to last until past midnight, and he should be glad to hear what the members had to say on so engrossing a subject.

Mr. G. W. Simpson was of opinion that Mr. Dawson had treated the subject in so elaborate and conclusive a manner, illustrated, as it had been, with such demonstrable results, that there was scarcely room for discussion, in which opinion he was supported by the majority of the members.

The Chairman said there were several points of considerable interest brought forward in the two papers which had been read. First of all, in Mr. Oakeshot's paper it was stated that the conditions requisite for discoloration of the silver coins were only present after a *very long* exposure to the action of the hyposulphite; and Mr. Dawson, who had treated of the "measly" effects produced, had most satisfactorily shown the actual condition of the substances formed.

Mr. Barber said the print which had been sent up by Mr. Oakeshot, and in which there were spots, had been fixed with cyanide of potassium, and not with hypo. at all.

The Chairman said the spots were not "measly" ones, but caused by the cyanide of potassium effecting a partial solution in the size of the paper. On putting the print into water these spots would instantly become perfectly transparent.

Mr. Dawson, in reply to the Chairman, said that "measly" spots were always produced in a very weak solution. One specimen of the paper he had exhibited was about six years old.

The Chairman said he should like to know if the difference between albumenised paper coagulated by heat or otherwise and that which had not been coagulated had ever been tried.

Mr. Dawson said the specimen shown had been coagulated; for some years ago he always did coagulate his albumen.

The Chairman said Mr. Dawson had spoken of having thrown down sub-chloride of silver, which certain gentlemen had stated did not exist. Was any test applied?

Mr. Dawson observed that it could only be that, or sulphide of silver, or hyposulphite of silver, but it was neither of the latter, as proved by the tests he applied.

The Chairman remarked that stale albumen was used by some manufacturers. One day, on entering the room of a person who prepared albumenised paper in large quantities, he perceived an unpleasant odour, and was told that they could not work the albumen unless they used stale eggs for the purpose, though of course this was an error.

Mr. Hill said he never had a "measly" print, which was probably owing to his employing a strong solution of hypo. He used Saxe paper, and sometimes there was a small spot like grease in the centre, which blackened in the light on drying.

Mr. Barber observed, that when Mr. Oakeshot was in town he showed him some prints in which, upon the albumenised paper, there was a kind of bluish "blur," which he attributed to putting the paper between steel rollers. He (Mr. Barber), however, had never any "measly" pictures himself.

The Chairman could add evidence of having produced "measly" pictures, some purposely; and he had arrived, by inductive reasoning, at the same conclusion as Mr. Dawson had done by direct experiment. When in an acid toning bath, if the print were removed suddenly, without washing, to the solution of hyposulphite of soda, it frequently produced these "measly" appearances. By passing between steel rollers, under very great pressure, the fabric of the paper was much compressed, and might readily have blisters formed.

Mr. Simpson remarked that, in place of passing the albumenised paper between steel, if passed between copper rollers the particles adhering to it would cause bad results to be produced. He had met with "measly" prints arising from the blistering of the paper. This was always in the case of Rive paper.

Mr. Dawson had never found any "measled" from that cause.

The Chairman said, with regard to measly spots, he had always been able to produce them on all papers that he had used, by *floating* the picture to be fixed *on* the hypo. solution, instead of immersing it.

Mr. Dawson said the measles could be produced on any quality of paper, provided the hypo. did not exceed ten per cent. in the fixing solution.

Mr. Hill remarked that the valuable communications recently received proved very satisfactorily the advantage of recording failures.

Mr. Barber exhibited two bottles of solution — one clear and colourless, containing a solution of cyanide of potassium, in which a slip of silver foil was entirely dissolved; the other a solution of hyposulphite of soda, with a similar strip of silver, but, partially dissolved, the colour of this solution was of the same dirty brown as the measly spots so often referred to, and evidently showed that, while the hypo. dissolved the silver, it at the same time set up decomposition in the compound almost contemporaneously with its formation.

Mr. Legg exhibited a negative on a collodio-albumen plate that had been kept eight months before exposure.

The Chairman exhibited two by Fothergill's process, which had been sensitised on the 19th June, 1859, and exposed respectively on the 3rd and 8th May in the present year. There was a minute single spot on one plate; the other was perfectly free from spots or stains of any kind.

Mr. Hill said the plates appeared as good as new.

The Chairman said it was, at all events, evidence to prove it to be possible, if the right means were taken, to keep the plates without being deteriorated—at any rate, for a considerable length of time. He did not, however, recommend the keeping longer than necessary under any circumstances.

Mr. Moginie's tent was erected in the room, and obtained a considerable share of attention. [For description, see page 177.]

The meeting then adjourned for the recess.

The next meeting of members will be held on Wednesday, Sept. 26.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A meeting of this Society was held on the 6th instant, at the Rooms of the Literary and Philosophical Society, Mr. W. T. Mabley in the chair.

The Secretary read a circular which had been received from the Literary and Philosophical Society, inviting the Society to join them in sending a deputation to Oxford, to co-operate with the other societies of Manchester, in inviting the British Association for the Advancement of Science to hold their meeting for 1861 at Manchester. The Secretary then read a resolution, which had been passed that evening by the Council, appointing Mr. Samuel Cottam, who would be in Oxford at the time, to represent the Manchester Photographic Society, and to join the other societies in the invitation to the British Association to come to Manchester in 1861.

Mr. William Hooper was unanimously elected a member of this Society.

The Secretary laid on the table two large and beautiful prints, taken by the collodio-albumen process, by Mr. H. Petschler, and presented by him to the Society's portfolio. A vote of thanks was passed by the meeting to Mr. Petschler for his contribution.

Some very interesting discussions took place on various subjects.

The Chairman said he had, during the last week, been to the south of England, and had taken some of Dr. Hill Norris's plates, which had turned out very satisfactory; he had not, however, yet printed from them, and would not say the negatives were without defect. He found the fixing reduced the intensity very much, and seemed to take away the half tones, but he thought this might be avoided by carrying the development further. The Chairman further said Dr. Hill Norris's plates required about twice the exposure necessary for the Taupenot process.

Mr. Hooper gave some explanation of a turpentine waxed-paper process, as practised by him, and with which he had been very successful.

After a general discussion upon this subject,

The HONORARY SECRETARY called the attention of the members to the subject of the proposed Exchange Club. He had now fifteen names down on the list, and it was thought they would be quite sufficient to commence with. The following regulations for carrying out the arrangements of the Exchange Club were agreed to:—

1. That the whole of the members of the club should form and be the committee to carry out the arrangements.

2. Specimen prints, for selection, to be sent by the members of the Club to the Secretary of the Manchester Photographic Society, on or before the meeting held on the first Wednesday in July next.

3. The decision as to the admission of prints for the purpose of exchange to be made at the ordinary meetings of the Society in August next.

4. The required number of prints for distribution to be sent to the Secretary unmounted, on or before the October meeting.

After passing a vote of thanks to the Chairman, the proceedings terminated.

OBITUARY.—It is with considerable regret that we record the decease, on the 29th ult., of Mr. Samuel Buckle, late of Leamington, and formerly of Peterborough, at the age of 51. Though not engaged in photographic pursuits for some time prior to his death, his former connexion with our art demands notice at our hands. He was a clever manipulator with the original Talbotype process; and his productions at the period of the Great Exhibition in 1851 stood prominently forward, and contributed by their excellence to induce photographers to unite in forming the Photographic Society. His selection and treatment of subjects were judicious and artistic; though he confined himself principally to a moderate size (generally 9 inches by 7 inches). For some cause with which we are not acquainted, he made no attempt to advance with the times as far as the production of negatives was concerned, and he was so opposed to the use of albumenised paper for printing, that we do not remember ever to have seen a picture of his on this material. Towards the latter part of his life he abandoned photography altogether, so that those who have only recently become followers of our art are scarcely acquainted even with his name, but it is one which must ever be associated with the popular rise of photography.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER VII. *(Continued.)*

The chin will partake of just a little of the colour applied to the cheek, so will the nostril and the ear.

The colour for the cheek may now be stippled over the whole face, excepting only the principal lights, but should by no means produce a very positive effect.

THE HAIR.

(See Maxim 45.)

As the colour of this will materially modify the general effect, you had better at once wash in the local colour. Indian yellow, with a slight portion of Venetian red, as your subject is fair, will form the wash. This must be used strong to kill the photograph, which is sure to be very much too dark, unless you have induced your printer (who is, however, not always very manageable in an artist's hands) to procure you a proof in which the hair has been rendered rather more opaque in the negative, or (by the aid of his aforesaid very useful bits of wool) printed but faintly in the positive you are colouring. A little warm sepia will serve for the darker portions, and the same used stronger will also answer for the darkest shadows and divisions. The high lights may be put in with white and yellow ochre, between which and the shadows place a cool grey, formed with cobalt and Venetian red, with a slight touch of madder pink. This same grey will answer admirably for softening the outlines of the hair into the flesh. When, however, this process does not give the desired colour for the hair, you may choose from the following list that mixture which most nearly approaches its apparent hue:—Raw sienna—warm sepia and Indian yellow—raw umber, or ditto with Indian yellow—burnt umber—yellow ochre and burnt umber—cold sepia—Vandyke brown. Having selected your colour, wash it over the whole of the hair. Many other mixtures for this purpose will suggest themselves in the course of your practice.

Refer back to remarks upon this subject under the head of "touching," and see Maxim 45.

THE NOSE.

Work (with the same tenderness and faintness of touch which I have so continually recommended) a *little* cobalt and Indian red* over the shadow tracing the outline of the nose, preserving the edges as indefinite and soft as is consistent with the due preservation of form. Put in the aperture of the nostril, in a series of faint touches, with vermilion and Indian red, and, with a touch or two of lake and burnt sienna, indicate the darker portions of this aperture as you find them in your "plain guide." The high light upon the tip of the nose may be got with a touch of Chinese white, and the less brilliant but conspicuous light running down this feature opposite the shadow* may be obtained by leaving it out when you are strengthening the tints about it.

* This must not be mixed to a cold or slaty hue.

THE CHIN, &c.

The chin is to be carefully and gradually rounded out with the tints already given. Detecting the faint reflected light beneath the shadow you may, by strengthening the first, give it more effect; and, unless the colour of the object reflecting this light decide otherwise, keep it warm.

Having proceeded thus far, pause, and carefully examine your work. If any lines appear hard and harsh, soften them by working upon their edges with a series of tints and colours, selected with a view to softly and harmoniously uniting the two edges, which are so abrupt in their meeting. If this grey, that pink, or this yellow hue are too positive, or do not harmonise, subdue them with the same patient care so urgently and frequently referred to. If that shadow has so hard an edge that it looks more like a patch of paint than a shadow, soften it into the lighter portions with warm and cool greys, using the warm first and the cool last, and keeping the first nearest the edge of the shadow, &c. Remember that all the flesh tints should melt imperceptibly into each other; that the touches must be very lightly applied, and without overcharging the brush with colour. Work up the dark tints very gradually. Put on the washes *very* pale; endeavour to keep them even and flat; and, to soften their edges, just touch upon them with a brush merely moistened with pure water; apply a wash as expeditiously as you can, and do not disturb it by touches, until dry. I am repeating myself again! you say. Well, and so I must, if I want to make an impression upon such material as beginners are composed of, as drops of water do on stone.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. WALL, Esq., 11, THE TERRACE, WALWORTH.

A LADY.—C. A. L.—M. WARDLEY.—These correspondents will find replies in the continuation of my lessons in the present number.

ROBERT ROCK.—If you will refer to the lessons already published, you will discover the information you require.

NORTH LONDON.—I must test your patience. To give information here, which I must necessarily repeat in the coming matter, would be hardly fair. Please to excuse me. The specimen has not yet reached me, criticism will therefore be given in the next.

EMMA.—Your specimen is very neatly and carefully coloured; but too little has been done to destroy the terrible blackness of the shadows. [Black opaque-looking shadows would destroy the best painted flesh in the world.] Work over them with a little Indian yellow and madder pink.

Foreign Correspondence.

Paris, June 11, 1860.

I SEE, by a foot-note to my foregoing letter, that you do not share the favourable opinion which I expressed with regard to Woodward's solar camera. I am glad that this difference of appreciation occurs at the very outset of my correspondence; for, while it proves to your readers the complete independence of my judgment towards yourself, it will, at the same time, be an assurance of the impartiality which I maintain towards the inventors and artists to whose labours I call your attention. I have ever thought that, in publications like yours, such independence is rigorously necessary. A journal whose special mission it is to aid by publicity the progress of a new art or science, can efficiently fulfil that mission only so far as it stands free from *coterie*—an impartial organ for all. It will then be well understood that for the opinions put forward in these letters I alone am responsible; and I may add, that I shall see with pleasure that you or your readers discuss those opinions, for, in the course of such controversy, useful hints are often elicited. That being said, I will begin by proposing a motion, which I hope to see seconded by you, for its adoption seems to me to be of urgent necessity. English photographers have a valuable quality—one which their French brethren, unfor-

* In bad photographs these more delicate details are swallowed up in a flat mass of white.

tunately, do not possess in an equal degree. I refer to the liberality with which they publish their processes and discoveries of greater or less importance, and even their failures—in fact, everything in their experience which is likely to contribute to the progress of their art. It is, however, to be regretted that the propagation of this useful information is in part impeded by the diversity and the complicated nature of your weights and measures. In spite of long practice in this kind of labour, we are at each moment checked when translating the communications made to photographic societies or journals by the difficulty of changing the quantities mentioned with satisfactory accuracy. You have weights of different kinds for solids and for liquids. You have ounces, grains, drachms, minims, and even scruples—the two last designators do not figure in any comparative table. How can we find our way through such a labyrinth? I will not propose that you should adopt our decimal system, which is so simple, but would it not be possible to adopt in all formulæ a uniform system? Could you not count by parts in weight or volume, so as to be understood in all languages, or at least confine yourselves to grains and drachms? I put forward my proposition in all humbleness, but certainly there is something to be done in the interest of all.

The *Lumière* gave, in its number of the 2nd of June, a note presented by Mons. Poitevin to the French Photographic Society on his printing process (gallate of iron printing process). I call your attention to this note, which you may perhaps deem worthy of reproduction in full. I will give you the *resumé* of it. Mons. Poitevin makes a solution of ten grammes of perchloride of iron in one hundred of water, adding three grammes of tartaric acid. He applies the paper to this bath, and then allows it to dry naturally; but, before employing it, he dries it completely in a gentle heat. The paper thus prepared is of a dark yellow colour, but when dry and exposed to the light it soon becomes completely white. Ten or twelve minutes' exposure to the sun suffices; in fact, one is guided by the discolouration of the paper. To facilitate and accelerate the printing, sulphocyanide of potassium is added to the above-mentioned solution in sufficient quantity to give a blood-red colour to the paper as it dries. The picture thus obtained in red upon a white ground, is fixed and rendered ink-black by being rapidly washed in common water, or in water containing chalk. The design is then plunged into a solution of gallic acid to which has been added some tannin. The image gradually takes an ink-black colour, and when judged sufficiently intense, is washed in common water, placed between sheets of blotting paper, left to dry, and is completely fixed. If for the gallic acid bath you substitute a weak solution of red prussiate of potash, you obtain from the negative a blue design upon a white ground. The results of this process are spoken of favourably; but I have not yet examined any specimens myself. As soon as I have had an opportunity of doing so, I will tell you what I think of them.

I await with impatience the approaching meeting of the Photographic Society, for we are promised for that day some interesting experiments, into which I shall of course hasten to initiate you. I spoke the other day of the vogue enjoyed by the card-portraits; they appear to be making their way into other countries. One of my friends, the son of Mons. Ferrier, whose name is well known to you, has just returned from a long journey in Italy and Sicily, bringing back with him a complete collection of those little portraits, and among them some to which passing events give an additional interest. There are, for instance, those of the King of Naples and the members of his family. My friend tried to procure, by way of companion picture, the card-portrait of Garibaldi which was made at Genoa; but our witty critic, Alphonse Karr, had slily bought up all the copies for his *Guêpes*, a humorous journal which he conducts at Nice. I should not be astonished to see one of these days in our publishers' windows the visiting card of the Emperor of China or of King Kamehameha. But the following is a kind of portrait which had not yet been imagined. Messrs. Bisson Brothers, whose frequent journeys among the glaciers of the Alps have familiarised them with all the difficulties which an operator may meet with in those regions, have had a singular idea which they are about to put into execution. They start in a few days for Chamounix in order to make a new ascent, in company with Auguste Balmat and his guides, and when arrived upon the summit of Mont Blanc, can you imagine what they intend to do? Why, to take the portraits of those tourists who shall be bold enough to climb up to that lofty operating-room. Is not that a truly original idea? and does it not betoken a hardy pluck? Bold as the enterprise may appear, I doubt not that it will be carried out; and in spite of the relatively high prices fixed for these portraits (500 francs), I am persuaded that amateurs will not be wanting. As to competitors, I hardly think Messrs. Bisson need fear any upon the ground they intend to take up.

A clever photographer of Bucharest, Mons. Ch. Pap de Szathmari, who has already produced some very remarkable works, has recently passed a few days in Paris. He showed us some very curious specimens of relief engraving upon zinc, which he obtains by transferring a collodion picture upon a plate of that metal. He performs this operation very cleverly. The object which he has had in view is the production, at the smallest cost possible, of a topographical map of Wallachia, with the printing of which the government of that country has entrusted him. This is an important application of photography, and one of those in which the art may render the largest practical services, especially in the hands of experienced men such as Mons. Szathmari.

When I next write to you the meeting of the French Photographic Society will have taken place, and have furnished me, I trust, with some interesting facts, which at the present moment are far from being abundant.

ERNEST LACAN.

TO OUR READERS.

To meet the additional expense incurred for carriage and postage of this Journal throughout the Provinces, arising from the great bulk it has now assumed through the increased amount of matter published in each number, our Provincial Agents will be compelled to charge all copies issued after the present number at 4d. each. The price to purchasers in London and Liverpool will remain the same as at present, namely, 3d.; and subscribers can still have it forwarded direct from the publisher as heretofore upon payment of 8s. per annum IN ADVANCE.

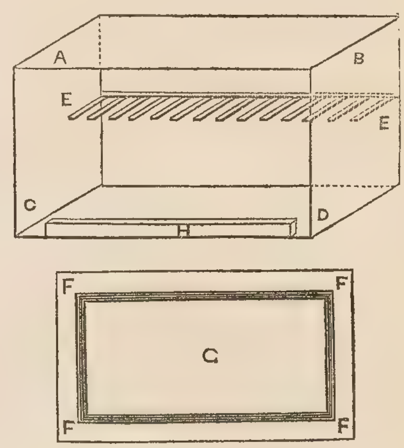
Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

RACK FOR DRYING PLATES.

To the EDITOR.

SIR,—The annexed sketch may probably be useful to some of your readers who, like myself, may have been puzzled for an effectual means of draining and drying their sensitive plates.



ABCD Mahogany box, twenty-four in., by twelve in., by six in.
EE Rails for supporting the prepared plates.
FFFF Shutter or door sliding in a groove.
G Yellow glass.
H Narrow gutta percha dish.

The bottom of this box is to be covered with blotting paper, and is capable, according to the above plan, of drying twelve stereo-plates, the tops of which rest or lean against the rails EE, which should be made of glass tubing, as wood will stain the plates. A narrow gutta percha dish should be placed inside the box, between the plates and the shutter, in which should be kept a little sulphuric acid to absorb the moisture from the plates.—I am, yours, &c.,

1st June, 1860. THOMAS CLARKE.

[We have had in use for some time an arrangement not unlike the foregoing in *appearance*, but far more effective, the rails being made of an elastic kind of wood (lancewood), with a small rectangular hole near the extremity, the plates being put on end anglewise, the lower angle in the trough (or in our case, between two slips of glass about the eighth part of an inch apart), on the upper angle in the hole in the elastic rail which is "sprung" on to it. Any number of plates may be put in, and the whole turned topsy-turvy even, without upsetting the plates, or allowing them to strike against each other. We got the hint from our friend, Mr. Rosling; but we do not know whether it was his own contrivance, or whether he received it from some other photographer.—Ed.]

UNCERTAIN FORMULÆ AND DOUBTFUL LOGIC.

> "He was in logic a great critic,
> Profoundly skilled in analytic:
> He could distinguish, and divide
> A hair 'twixt south and south-west side."—*Hudibras.*

To the Editor.

Sir,—A few remarks of mine on the folly of slovenly manipulation made at a recent meeting of the South London Society, have obtained for me the doubtful honour of the notice of your correspondent "Israel Holdsworth." Mr. Holdsworth is angry, and writes with the recklessness and lack of precision which usually characterise an angry man. I am somewhat disposed to adopt the reply of the giant who was questioned as to why he permitted his vixenish wife to thrash him:—"It pleases *her*, and don't *hurt* me."

I will, however, sir, by your permission, just point out one or two errors into which Mr. Holdsworth has fallen.

The report to which he refers is manifestly, to the meanest capacity, an abstract or condensed report, in which the remarks of the speakers are stated, as reporters technically phrase it, in the third person, in which it is impossible that the *ipsissima verba*, or exact words of the speaker, can be given, but instead thereof such an epitome as in the reporter's judgment most perfectly renders the meaning and intention of the speaker. This being the case, what becomes of Mr. Holdsworth's series of extraordinary *verbal* criticisms?

Again, if verbal quibbles have such a charm for Mr. Holdsworth, he will find, on a careful examination of the report in question, that I am not made even to mention his name, but merely to regard him as representing a class, the remark reported as mine being "that when *a* man (*ergo*, *any* man, Mr. Holdsworth) of such a stamp said he had no failures, it was more than probable that less partial judges would say he had no successes."

But enough, sir, of verbal criticism. What were the exact words that I made use of at the meeting in question I do not remember, but the remarks as reported accurately enough express my meaning. I have no fancy for following Mr. Holdsworth through his display of word fencing. Mr. Holdsworth describes himself as a "successful photographer;" but if he be as successful in producing a picture as he is in putting a proposition into the form of a syllogism, his photography and his logic may both serve as beacons to be avoided if not as guides to be followed.

Mr. Holdsworth asks why I did not show his statements to be erroneous? Simply because they were more calculated to cause a smile than to call for refutation. Inexactitude in formulæ and in manipulation has been, I believe, a fertile source of failures; but a letter like that of Mr. Holdsworth's is one of those evils which carry their own cure—its very extravagance rendering it harmless.—I am, yours, &c.,

G. WHARTON SIMPSON.

PERSPECTIVE.

To the Editor.

Sir,—In the last number of your Journal, Mr. Hannaford attacks Mr. Grubb for his letter on "Perspective." It is certainly quite true that to represent in a drawing a tower with vertical sides by converging lines is absurd—that is exactly what Mr. Grubb proves; but to say that he is therefore guilty of an Irishism is rather preposterous. It would seem that Mr. Hannaford sees some absurdity in the "converging perpendiculars," although he seems to have a kind of idea that it is right to make the perpendiculars converge. He ought to see something rarely ridiculous in representing the horizontal lines in nature by converging lines on the drawing. According to his way of viewing the subject, converging horizontals should be as absurd as "converging perpendiculars." Now I think it most objectionable to attack everything an Irishman says on the ground of its being an Irishism. I remember the bad taste shown by another writer in taunting Mr. Grubb for being an Irishman at the commencement of their discussion on lenses. In the present case the imputation is more than usually absurd, and only shows that Mr. Hannaford does not in the least understand Mr. Grubb's argument, which is both simple and *conclusive*. Moreover, Mr. Hannaford is guilty of a blunder, of which an Irishman would be ashamed, when he tells us to look down perpendicularly from a bridge on a line of railway, "so that the *point* of sight—the real *point* of sight this time—shall be in a position at *right angles to such line*."—I am, yours, &c., A. N.

Hereford, June 6, 1860.

DEVELOPING, TONING, &c.

To the Editor.

Sir,—I beg leave to bring before you a few things that have suggested themselves to me. First, Is it not time that The British Journal of Photography was made a weekly publication? You don't seem to get through with your matter, and it is tantalising to have so many continuations.

In the number for 1st June your Paris correspondent speaks about card portraits. I have seen a number done by Disderi & Co., 8, Boulevards des Italien, Paris, and they are very pretty. When I first saw them, I thought it would be of use to know by whose lenses they were done—for they had *great* depth of focus—and what developer was used. The negatives do not seem to be intensified, the prints are pure in the whites, with good blacks and excellent half-tones, and, what adds to their beauty, the figures are well posed. Perhaps your correspondent could say a word on these points.

In the last number you answer R. Mulock on proto-nitrate of iron, and say, "It should be used *without* any acetic or nitric acid, and, when freshly made, the positives developed with it are of a brilliant metallic hue." I have sometimes forgotten to put in the acid, and got very dark cloudy pictures. Hardwich recommends acid, and Keith and others publish that they use it. Was there no *mistake* in your answer?

Mr. Hughes, in his paper on printing, suggests toning a great number of prints at once, but recommends beginners not to have more than a dozen in the bath at one time. When I put several prints in at one time, some of them tone unequally, and have red spots.

When prints are long washed, say five or six hours, the toning bath seems to have little effect on them, and if washed for two days they won't tone at all. What is the reason?

Hoping you will excuse these rambling remarks, I remain your *own* and The British Journal of Photography's well-wisher,

Glasgow, 8*th June*, 1860. J. R. A.

[We are not of opinion that a weekly issue is advisable: others have tried it, and the result would by no means satisfy us. Something more than novelty is required in the matter, and be assured that "easy reading requires hard writing"—the element of *thought* is a *sine qua non*.

Our Paris correspondent will possibly reply to your inquiries.

There is no mistake in our reply to R. Mulock. Proto-*nitrate* of iron, made as there directed, does *not* require free acid.

You must fail, because you allow your prints to *touch* one another, and enclose air bubbles between them. Keep them moving about until toned. There must be some error in your manipulation; but why wash so long?

Thanks for your good wishes.—Ed.]

INSTANTANEOUS VIEWS.

To the Editor.

Sir,—Being desirous of taking instantaneous pictures, will you be so kind as to inform me what bath, whose collodion, and what developer I should use? Can you also suggest a simple form of instantaneous motion-shutter, to be fitted to the hood of a quarter plate portrait combination, and oblige?—I am, yours, &c. A. Y.

London, 22*nd May*, 1860.

[In taking instantaneous views it is necessary to have the neutral nitrate bath and an iron developer in good working order; use a good negative collodion, and any instantaneous shutter, for instance, that introduced by Messrs. Murray and Heath. If you wish to take stereoscopic pictures instantaneously, you must use a pair of lenses (whether *single* or double combination) simultaneously, and you may then employ an instantaneous movement contrived for this purpose which we lately introduced to the notice of the London Photographic Society, the pattern of which is in the hands of Mr. Melhuish, of the Haymarket.—Ed.]

"STOLIDAM PRÆBET LIBI VELLERE BARBANE."

To the Editor.

Sir,—I remember reading of a wonderful Yankee who, when his crops wanted a shower, sent up a rocket to bring it down; but I was somewhat surprised to find such a heavy shower of words brought down by the playful little squib discharged at a recent meeting of the South London Photographic Society, by Mr. G. W. Simpson. Mr. Howard's pictures and his careful manipulation are both well known to us, and the first are about the best argument in favour of the last that could be brought forward, and Mr. Israel Holdsworth must advance stronger evidence in proof of the superiority of his own productions than the mere assertion which he seems to consider "the clenching argument." Permit me to try my hand at a syllogism after the pattern of Mr. Holdsworth's. According to Walker, to demonstrate is to prove with certainty.

He (Mr. Holdsworth) says, a fact can be demonstrated but not proved, to demonstrate is to prove; *ergo*, a fact cannot be demonstrated.

Permit me also to tell Mr. Holdsworth that when a reporter gives a speaker's own words they will be found between inverted commas.

Hoping these few lines may not bring about another epistle from the same quarter.—I am, yours, &c.,

A MEMBER OF THE SOUTH LONDON SOCIETY.

June 2*nd*, 1860.

AN OPINION ON "COMPOSITION PICTURES."

To the Editor.

Sir,—All lovers of true art, and all those who are interested in the development of photography in its higher flights, must have been annoyed at the letter purporting to be written by "Mrs. Spriggins," in your last number, attempting, with rough but feeble wit, to cast ridicule on an artist who has done much to raise the camera from a mere copying machine into an instrument for recording artistic thought. Mr. Robinson's merits and ingenuity are, I am sure, safe in your hands. You have always upheld him (as you have others) in his efforts to advance photography, therefore anything in his defence from me would only be superfluous; but I trust that I may be allowed to say, I hope he will take no notice of such silly nonsense, but will continue to delight the photographic world with his charming pictures for many years to come.

I cannot help pointing out a circumstance which I think requires notice, namely, that whenever anything out of the usual way is brought before the public there is always a set of envious men who, not having sufficient talent to do the same themselves, try to bring the novelty into contempt. In your number for the first of May a correspondent attempts this, but instead of proving Mr. Robinson to be ridiculous, as appears to have been his intention, he only exhibits his own want of knowledge, and calls down upon himself an editorial reprimand, which should have deterred him from attacking, in your last number, another gentleman; but some men, having no other mode of emerging from their well-merited obscurity, *will* rush into print, and if they cannot write sense, make up for the want of it in quantity, occupying space which might be much more ably filled by others.—I am, yours, &c.,

FAIRPLAY.

[Our fair correspondent, like most of her sex, is a warm advocate; but is she not a little too hasty in attributing evil motives where such may not exist? We have always upheld freedom of discussion; and what has been designated "an editorial reprimand" was not so intended, but merely a protest against our being supposed to entertain similar opinions to those expressed by our then correspondent. Had we regarded the opinions as expressive of malevolence they would have found no place in our columns. In the present number we publish an article from a valued contributor, an artist and photographer, taking the view totally opposed to our own. We believe that we can point to what a lawyer would call "a flaw in the indictment," but that we shall leave to another opportunity—partly because we wish to let others have the opportunity of finding it out and exposing it, and partly to let each side have a fair hearing. Of the good faith and good feeling of our contributor we do not entertain a doubt. Fair controversy, conducted in a spirit of consideration, tends materially to elicit truth. We are obliged to the lady who, under the signature of "Fairplay," has expressed her appreciation of Mr. Robinson's labours, shared in, as we are well assured, by many; and we are not the less pleased that it has afforded us the opportunity of declaring our conviction that the contest is purely a friendly one.—Ed.]

ALLEGED POISONING BY CYANIDE OF POTASSIUM.

To the Editor.

Sir,—It is a well-known axiom in philosophy that, "if each one of two quantities be equal to a third quantity, they must of necessity be equal to each other."

I am led to make this remark by a note in Mr. S. Highley's Table of Antidotes, where it is said that two and a-half grains of pure cyanide of potassium are equal to one grain of anhydrous prussic acid, or fifteen minims of the acid of the London pharmacopœia.

Now the acid hydrocyanic dil. P.L. contains two per cent. of anhydrous acid, consequently an *erratum* should be inserted—for "fifteen" read "fifty." Is it customary in a printing office for one person to read the manuscript and another to set up the type? If so the error would be easily accounted for by the similarity of sound in the two words without attributing carelessness to the author.

In your review of Mr. Hockin's "Practical Hints," you notice the case of a photographer who lost one of the bones of his finger, and nearly lost his life, through the sore being irritated by cyanide of potassium. Some years ago a similar case fell under my professional care, differing, however, in a few particulars. The patient was not a photographer, but an old woman; she was not fixing a picture, but scrubbing a floor; and the material she was using was not cyanide of potassium, but carbonate of soda. Her thumb was wounded by a loose wire at the back of the brush, and the inflammation caused by the soda extended so rapidly up the arm, that she lost, not only the first joint of her thumb, but her life also. Here I believe that the irritating cause was the *soda*, and probably the same effect would have resulted had it been combined with hyposulphurous acid instead of carbonic. *Irritation* is not the physiological effect of cyanogen; and the second case that you mention may be explained by the paralysing power of the vapour of hydrocyanic acid acting on the respiratory nerves, and rendering voluntary efforts necessary to the continuance of breathing. Were the nerves of voluntary action also paralysed, death (not inflammation) would be the *immediate* consequence.

Was not the physician in question in the habit of using his solution so strong as to clear the picture *instantly*, and to require some dexterity in pouring it off before it had done any mischief?—I am, yours, &c.,

June 4th, 1860. M.R.C.S.

[We have to thank our correspondent "M.R.C.S." for pointing out the error in our Table of Antidotes: it escaped our notice in correcting the proof. The note was inserted simply for the purpose *of warning* those unacquainted with the composition of cyanide of potassium that it contained a body *well known* to be of a deadly nature; so far *the oversight* as it stands is of no great consequence, nevertheless, as a statement of a scientific fact it is erroneous: an *erratum* will be inserted.

Like Mr. Hockin, "M.R.C.S." seems to entertain a doubt as to whether the vapour arising from solution of cyanide of potassium *as ordinarily employed* in photography is baneful in its effects on the human economy. Dr. Taylor, in his "Treatise on Poisons," refers to several cases where serious effects presented themselves on inhaling *the vapour* of prussic acid *even when in a diluted form*. Scheele is said to have died from breathing the vapour of *the diluted* acid. It is well known that those who work in electro-plating and gilding factories have their nervous systems affected by habitually being in an atmosphere contaminated by the prussic acid vapour given off from the vats of cyanide of silver: the symptoms are frequent swoonings and loss of memory. We are personally acquainted with a gentleman who was formerly a superintendent at one of the large electro-gilding factories, but his health became so seriously impaired that he was obliged to throw up a very remunerative engagement.

If the habitual inhalation of the vapour from cyanide of silver at electro-plating establishments produces serious effects on the workmen, why should not similar results accrue to those who constantly employ cyanide of potassium, during the hottest hours of the day, in developing-rooms, which, as a rule, are small and badly ventilated?

We know of several cases of impaired health, which the medical attendants have *attributed* to their patients spending too much time in the developing-room where cyanide of potassium had been employed as a fixing agent. As prussic acid in classed amongst the Neurotic Poisons, would not the state of excitement into which amateurs sometimes work themselves on taking photographs, induce a condition very favourable for the poisonous vapour to produce its peculiar effects?—S. H.]

ANSWERS TO CORRESPONDENTS.

Errata.—In the Table of Antidotes given in last number under Treatment of Sulphuric Acid, &c., for "tracheometry" *read* "tracheotomy." In Note to Cyanide of Potassium, for "15 minims" *read* "50 minims."

Star Cross.—Ordinary chloride paper will serve your turn best.

Philomel.—The name is vile, as you say, but the results are good, nevertheless.

Conscious.—Time will show whether we are right or not. You begin at length to doubt your estimate: you will end by reversing it.

In a Mess.—In our opinion he is a very unsafe guide, so we do not wonder at your predicament. Get Hennah's pamphlet (Knight and Son); you may rely upon that.

T. B.—Your communication having already appeared in another journal we must decline it, with thanks.

Kangaroo.—Do you adopt this designation because you *jump* to a conclusion? You may be right, but you have no evidence of it.

Bothering Amateur.—We did not *recommend* the "linseed tea" process exactly, but *assented* to its efficacy. We will endeavour to meet your wishes in our next.

Omicron.—We prefer metal plate boxes (tin) for preserving dry plates; but the form is also a matter of importance, so as to rigidly exclude the possible access of light.

Robert Hulett.—Reply to your queries in next number. Had your note been forwarded direct to the Editor instead of to the Publisher, a reply might have appeared in the present publication.—[See usual Notice at foot.]

Objective.—What novelty do you suppose there is in this designation? The word has been in use in this country amongst scientific men who employ microscopes, telescopes, &c., for the last fifteen or twenty years, to our knowledge—probably much longer. Who can have hoaxed you by asserting it to be a novelty?

X. Y.—The addition of nitrate of silver to meta-gelatine ought not to occasion any turbidity; but if chloride be present, a cloudiness will result on adding diluted nitric acid and boiling. We advise you to filter the solution if possible, or, if that cannot be done, to begin again with fresh chemicals.

W. H. Walter.—Read Mr. Wall's articles on Colouring. We have referred your query to him, and he replies that, for this purpose, he uses water colours—Indian ink, madder brown, &c., with a little gum water, and, if the paper be *very* highly albumenised, a little ox gall may be added. Perhaps you charge your pencil too liberally with colour, or grease the surface in some way unnecessarily.

R. L. Dick.—For positives your bath should be slightly acid with nitric acid; add to it *one* drop, and try a plate. The proto-nitrate developer changes to a reddish colour as it decomposes, and simply becomes inert. Our statement in reply to R. Mulock applied to real proto-nitrate of iron made as there directed. We do not remember to what particular formula of Mr. Hardwich's you refer. When in town you cannot do better than attend Mr. Hardwich's classes, at King's College, to learn the practice of negative operations.

No Chemist.—The old toning and fixing bath in one ought never to be used. The method described by Mr. Hughes, in No. 113, is a very good one, and economical withal. It *is* absolutely necessary to wash the prints before toning; and heating the toning bath not only saves time but produces better results. The instrument you name can be procured at Mr. Hughes's establishment in Oxford Street. The number of prints fixable in a given quantity of hyposulphite of soda would vary according to whether they are all fixed in a short space of time or not. If the solution decomposes by keeping you had better make fresh; but so long as it remains free from sulphurous smell you may employ it. The quantity named ought to fix fifty prints of the given size at least.

Received.—C. Jones—R. Turnbull—Luna—Justitia.

☞ The "Table of Antidotes," published in the last number of this Journal, having been carefully revised by Mr. Highley, has been Reprinted in a useful shape, suitable for hanging up. Price 6d., or free by post 7d. [*See Advertisement.*]

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 121, Vol. VII.—JULY 2, 1860.

It is not without considerable regret that we find two of our valued friends ranged on opposite sides regarding a question of very material interest to photographers, especially to the art-loving portion of them. As is generally the case under similar circumstances, where both sides are actuated by perfect integrity, and a hearty desire to further the advance of the artistic element, the difference of opinion existing may be readily traced to misapprehension on the part of one or both of the contending parties respecting the motives or views of the other. We refer particularly to the controversy between Mr. Wall and Mr. Robinson, on the subject of "Composition Printing from Several Negatives," connected with which two articles will be found in the current number of this Journal, and one appeared in our last, in addition to sundry comments, grave and facetious, which have previously "cropped out" in previous numbers, to all of which we solicit the attention of our readers. The immediate cause of the discussion arose from the fact that Mr. Robinson, at the instigation of the Council of the Photographic Society of Scotland, wrote a paper, the title being that above quoted, which was read at one of the meetings of the Society named. Mr. Wall takes exception to the course recommended in that paper, as, in his opinion, injurious to the cause of artistic excellence, besides destroying the chief value (to him) of a photograph — its truthfulness of representation; but certainly that which is regarded as the greatest aggravation of the alleged offence is, evidently, that it is committed by aid of the "paste-pot and scissors," which are abominations to an artist.

We have a few words to offer relative to each of these points. Mr. Robinson, for one of his compositions, received the prize medal awarded by the Photographic Society of Scotland for the *best group* displayed in the late exhibition of photographs held at Edinburgh. His paper was written as descriptive of the *modus operandi* by which he produced the specimen for which the medal had been conferred and similar compositions, and was therefore necessarily devoted chiefly to mechanical details. Mr. Robinson himself is quite conscious of, and admits, his inability to convey to others readily and clearly the ideas which are present to his own mind, consequently there is no wonder that his attempt to do so was more or less a failure.

Absolute truthfulness of representation is not a necessity of photography; on the contrary, there are many known departures from this assumed absolute correctness — for instance, the very tools employed, the lenses, introduce certain evasions of strict veracity; the equivalent effects of various colours, as regard light and shade, are not truly interpreted; and even the degree of variation is influenced by the nature of the chemicals used. But setting all of these considerations aside for the moment; as "composition pictures" assume only by their very designation to be regarded as pleasant fiction, their want of truthfulness—which is not claimed for them, but absolutely ignored—cannot be reasonably alleged as an objection. If this were admissible what becomes of the morality of Mr. Wall's own occupation? It is nothing that by his artistic skill and talent as a colourist he adds a new charm to the best productions of the camera, for by so doing he destroys the assumed absolute truthfulness of the original. If an offence be committed it does not appear to us any the less heinous for being executed strictly *secundum artem* than by the heterodox agency even of paste and scissors.

Mr. Wall admits that Rejlander "sails not under false colours;" surely we are not thereby intended to infer that Mr. Robinson makes any attempt to do so; in fact, the very candour of his paper which has drawn down the storm upon him, forbids our coming to any such erroneous conclusion. So much for the charge of a sacrifice of truth. But of course it will be argued that, if this charm be sacrificed, it is surely better to do it in such a way as will add to the artistic excellence than detract therefrom—granted; but is it absolutely *necessary* that by the use of paste and scissors, artistic excellence should be destroyed? Surely not, for even our worthy censor admits its existence in an eminent degree in some of Rejlander's charming productions, especially in that beautiful one, *The Head of John the Baptist in the Charger* (and, by the way, instead of criticising that picture ourself just now, we refer our readers to the close of Mr. Wall's article in the present number, as we fully endorse all his encomiums); need we say this was produced without preliminary decapitation, and therefore we fear that the obnoxious paste and scissors played an important part in the manipulation, yet there is no hardness of outline to offend the eye. Our friend has, however, already discovered the existence of Rejlander's paper to which we intended to refer him (see our number for 15th April, 1858), and he appears not a little pleased therewith, and with justice we must allow; but what becomes then of his stigma of "Patchwork?" truly it descends like a counterpane —no, a wet blanket—plump on the head of Mr. Robinson, whose "pictures and paper display the same idea" of "cruel cutting outlines," &c. That his pictures have many faults no one is more conscious than himself; but they have beauties too, and do display a considerable amount of conception, thought, and arrangement: witness his *Fading Away*, which, though a very painful subject, exhibits feeling and pathos in an eminent degree, in spite of some hard outlines which we admit to be present. Now these hard outlines are *errors of manipulation*, and not necessarily persistent after the use of paste and scissors, as we knew; for we had not forgotten Rejlander's "pencil of light"—his brush made out of a sunbeam—even though Mr. Robinson may not have yet acquired sufficient skill in its handling.

It is quite gratuitously assumed that Rejlander looks upon the paste-pot and scissors as *disagreeable necessities*, simply because he says that "an abler artist, with better means, could do a better thing;" and still more illogical is the assumption that *therefore* he agrees in the opinion expressed by Mr. Wall, that "a lens commanding a wide angle of view," &c., "and a good enlarging process, are the right tools to work with." On the contrary, we opine that the fact of his having adopted the other alternative, knowing at the same time so well what he was about, proves more satisfactorily than any words could do which course he judged most likely to accomplish his object. This is, however, but little to the purpose: it is not what A or B *thinks* the best, but what *is* the best to follow. We shall be only too glad to induce Mr. Wall to try his hand at "composition photo-

graphy" in any way he likes. We have no doubt that he will, if he undertakes it, produce something worth looking at.

Mr. Robinson's paper made no mention of conception, design, study—for a very simple reason: he could not suppose that any one would attempt a *composition* without it—he did not profess to teach that which Rejlander had already done, and done better than the former felt himself able to do; but he treated of that on which Rejlander touched but lightly or only hinted at—some portion of the necessary mechanical drudgery.

We have taken up the cudgels against our esteemed friend Mr. Wall, for in hitting Mr. Robinson he also hits us. We are a *particeps criminis*, for we frankly acknowledge to having encouraged him in his flagrant practices; and we feel that, where he fails, it is not owing to an absence of the mental element, but to a deficiency of manipulatory skill. In fact, he is no conjuror, simply because he tells you how he performs his trick.

The point first started with—the presumed impossibility of artistically combining portions of different negatives into one harmonious whole—having been abandoned, we are not going to enter the lists with Mr. Wall on the question of pure art, as regards this or that production; for the chances are that his weapons are better than our own, and that he has more skill in their use: moreover, the regions of art are his own familiar arena, his birth-place and home as it were; and, as "discretion is the better part of valour," and having no wish to be conquered, we prudently decline the contest, feeling by no means certain that if it came to argument upon the art-merit of any particular picture we might not be brought over to his way of thinking; for we hold it as indisputable, that though an art-amateur may fail to *discover* a beauty, yet if pointed out it cannot fail to be *perceived*, provided it be really existent, and not the mere chimera of the artist's brain.

A short anecdote may perhaps explain our meaning more clearly. A farmer giving evidence on a trial, was being cross-examined by the counsel on the opposite side, and the latter was getting more and more "put out" in consequence of the straightforwardness and good sense of the witness's replies, which did not tell in favour of his client. Not being able to find any other fault, he desired him very testily to "speak up!" for he could not hear him. "I do speak up as well as I can!" said the farmer." "The learned counsel means that you do not speak as loudly as he does," interposed the judge. "Of course not," replied the farmer, "'taint loikely—*it's* HIS *trade!*"

We feel that an apology is necessary for the length to which this article has extended, but trust that the interest of the subject will excuse us.

We notice an official announcement from the Spanish Minister, relative to the admission into Spain of scientific apparatus free of duty, for the purpose of making observations in connexion with the forthcoming eclipse of the sun, provided a bond be entered into for its re-exportation in due course. In this concession photographic apparatus is included; it therefore becomes our duty to record the fact for the benefit of our readers.

In the discussion that has been carried on for some time respecting the relative merits of different kinds of collodion, we regret to find that a species of jealous feeling very much prevails, of which our friend, Mr. Hardwich, appears to be the victim—and very unreasonably so.

The only possible cause for this injustice can be the erroneous impression that Mr. Hardwich is commercially interested in the manufacture of the article. This impression is evidently encouraged by such phrases as the following, viz., "Ponting's, Hardwich's, or Thomas's collodion, and *that of other makers*," which we find not unfrequently employed. Moreover, we occasionally see "Hardwich's collodion" mentioned in some advertisements. We can scarcely, therefore, be surprised at the existence of the misconception. We, however, think it very unfair towards Mr. Hardwich; for we know of a certainty that he is in no way commercially interested in the article, and, having so liberally and unreservedly given to the public the result of his labours, the imputation conveyed is a source of considerable annoyance to him. So far as the advertisements are concerned, were we in his situation, we should make very short work of the matter by absolutely prohibiting the use of our name. We hope, however, that our notice of the subject will, for the future, obviate any misunderstanding on this point.

We recently described some novelties in apparatus: we now notice a form of stereoscopic camera with which we have been much pleased—it is that lately exhibited by Mr. Hare at the North London Photographic Association. The whole of the apparatus fits into a light mahogany box—that is to say, camera, lenses, screw, slides, &c.—the total weight being very moderate in amount. The box forms the top of the tripod, the camera being attached to the same when in use by a screw in the usual way, so that it can revolve in azimuth. The camera is on the bellows principle; and though as a rule we do not prefer this form on account of its liability to vibration, we think that in this instance the instrument is free from that defect. The adjustment for focus is very conveniently arranged by means of a screw at the back, the lens fittings simple and rigid, and with but trifling weight, and can be contained within the body of the camera when in use, so that a contrivance for instantaneous exposure can be readily adapted in front without in any way interfering with ordinary arrangements. The various slides, &c., are contained in the box which forms the tripod head, and are accessible by a special side door in it, by which they are not only conveniently disposed, but are thoroughly protected from the possibility of the unauthorised intrusion of light.

We have recently examined also a contrivance, by the same maker, for an economical swinging back, having also the advantage of causing very little additional bulk, and allowing of movement in both lateral and vertical directions. The former movement is obtained by means of the sliding body passing through an elastic packing, a slot being formed in the plate of the binding screw, which admits of considerable play and yet can be firmly fixed in the desired position. The vertical movement is effected by the slide frame having a swing movement upon its bottom edge as a centre, and screw adjustments at the side. The cost of this arrangement is not above one-tenth part of that entailed by the ordinary arrangement for a swinging back—at least so we are informed.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 7.

The importance of the alkaline hyposulphites is almost solely due to their use in photography, and hence it is not to be wondered at that their reactions with the salts of silver are not familiar to chemists. In a former article we called attention to the importance of distinguishing between the two double salts of hyposulphite of soda and silver described by Herschel, one of which contains more silver than the other, and is far less easily soluble in water. Since that time we have carried our experiments further, and with results quite different from what we anticipated. Nevertheless, since experiment is the test to which every expressed opinion must be subjected, it will be better at once to describe what we have done.

The experiments were commenced by preparing the second or sparingly soluble double salt of Herschel, by adding the correct quantity of chloride of silver to hyposulphite of soda; and here it was observable to how great a degree this compound possesses a property, shared with it by many other substances, of remaining for a time dissolved in water in a proportion beyond the saturating point. The crystals may continue separating from the liquid day by day, for a week or more, and this even in a closed vessel where no evaporation is permitted. When, however, the separation has once taken place, it requires a very large bulk of water to redissolve the crystals, certainly not less than three hundred times their

weight, as far as we can judge by an experiment made rather hastily.

An aqueous solution of the above crystallised salt has a perceptibly sweet taste, and possesses the following reactions:—Nitrate of silver throws down a precipitate of hyposulphite of silver, which is at first white, but almost immediately becomes yellow and then brown. If, however, a little chloride of sodium be added to the solution of the crystallised salt before the nitrate of silver is applied, the mixed precipitate of chloride of silver and hyposulphite of silver then obtained does not spontaneously change in colour, but remains white, even in presence of an excess of nitrate of silver. Light acts upon this mixed precipitate, but the darkening is different in appearance from that which results when pure chloride of silver is exposed to the sun's rays. The solution of the crystallised double salt does not become at once milky on adding an acid, but remains clear for a time. A minute quantity of chloride of sodium added to the solution of the double salt causes a white turbidity, which is removed by ammonia. A larger quantity of chloride of sodium added to the solution at first causes turbidity, but afterwards clears up the liquid by redissolving the turbidity. A small quantity of iodide of potassium throws down iodide of silver, recognised by its colour; a larger quantity redissolves this iodide in the form of a double iodide of potassium and silver, which is again decomposed on dilution with water.

The above facts have much significance. They show us, in the first place, that the ordinary tests for hyposulphite, viz., its blackening with nitrate of silver, and its becoming milky with acids, may fail in some cases; and, secondly, they prove that there are conditions under which the affinities of chlorine and of iodine for silver are greater than that of hyposulphurous acid, that is to say, when the alkaline hyposulphite is not present in great excess in relation to the silver salt, or, more particularly, when the alkaline hyposulphite being in small quantity the alkaline chloride or iodide is in excess. In such a case, supposing the proportion of silver to be below a certain point, the chlorine or the iodine will take it before the hyposulphurous acid. Thus, if we make a solution of iodide of silver in iodide of potassium, and add hyposulphite of soda in minute quantity, no precipitation takes place, and on diluting such a mixture with water, so as to throw down a deposit of iodide of silver, hyposulphite of soda will be found in the supernatant liquid.

The inquiry will here be made:—What test is applied to detect the presence of the hyposulphite of soda in the above case? We have devised the following, which appears to answer: add, first, excess of iodide of potassium, if it be not already present, until the iodide of silver thrown down is taken up again; then drop in a dilute solution of *iodine*, when, if hyposulphite be contained in the liquid, the colour of the iodine will be removed by the conversion of the hyposulphite into tetrathionate. It may be mentioned, however, that a more simple test will often be sufficient to indicate the presence of hyposulphite, viz., *the taste*. When the hyposulphite exists in combination with silver the sweetness is perceptible even after extreme dilution; and with hyposulphite free from silver there is a persistent bitterness left on the palate which is not easily disguised. Our friend, Mr. Hadow, finds a solution of permanganate of potash to be a good test when organic matters are absent: the purple colour will be immediately discharged by even a trace of hyposulphite.

Reasoning on the facts now laid before the reader, it seems impossible to avoid the conclusion that the action of an atom of hyposulphite of soda upon an atom of chloride of silver, must have a limit short of a complete double decomposition; because, after a certain point, the opposing affinity of the chloride of sodium formed in the liquid comes into play, and tends to keep a certain portion of the silver in the state of chloride. If, however, a large excess of chloride of silver were present, then it might be conceived that the whole of the hyposulphite of soda would pass into the state of hyposulphite of silver, since the chloride of sodium would have a sufficiency of chloride of silver in excess wherewith to satisfy it and prevent it from offering any opposition. To put this to the test of experiment, a strong aqueous solution of chloride of ammonium was first saturated with chloride of silver, so that the smallest addition of water caused a milkiness. Into this liquid some of Herschel's crystals, containing an atom of hyposulphite of soda with one of hyposulphite of silver, were dropped. What then might be expected to happen? Surmises were out of the question, and it seemed better to wait and see what would happen. The result was that the crystals were quickly decomposed, clotty masses resembling chloride of silver remained at the bottom, and the solution on being tested was found to contain hyposulphite.

If, therefore, an alkaline chloride decomposes hyposulphite of silver, and the same alkaline chloride previously saturated with chloride of silver does so likewise, it is incomprehensible that chloride of silver, however applied, can be capable of removing the whole of the hyposulphurous acid from its combination with soda. Therefore at present we are at issue with Mr. Dawson, although previous to any actual trial we were disposed to give his views our most hearty concurrence. It will be better in every way to discuss the subject freely, since the whole chemistry of the hyposulphites is so complex that no one need fear a confession of having been mistaken. We therefore publish our results without an idea of being confounded if any one afterwards proves us to be wrong. Our confident belief is that the views now brought forward are sound; for having tried Mr. Dawson's experiments carefully, we cannot succeed in removing the whole of the hyposulphite from its combination with soda by agitation with chloride of silver. Hyposulphite still remains in the solution after a prolonged digestion, and defies all attempts at separation. It is of no use whatever to appeal to first-rate chemists in a case of this kind, and ask them their opinion: they will reply at once that the hyposulphites need more investigation, and that it is hard to say what would happen in a given case. Experiments must be made, and photographic chemists being most interested are the proper persons to conduct them. Many of the readers of this Journal will scarcely take interest in so abstruse a question, but some will doubtless see a new field for investigation opened before them, and will be inclined to enter into it.

We conclude this article by giving a summary of our results. When nitrate of silver is added to hyposulphite of soda, with the proper precautions to prevent spontaneous decomposition of the resulting hyposulphite of silver, two atoms of the latter will dissolve one atom of the former, and Herschel's sparingly soluble salt will be formed. It will require, however, rather more than two atoms of hyposulphite of soda to dissolve one atom of chloride of silver, since the chloride of sodium produced during the double decomposition exercises an opposing affinity. And when iodide of silver is acted upon by hyposulphite of soda, the quantity dissolved will be *decidedly* less than theory indicates for the above-named crystalline double salt, inasmuch as iodine is very strong in its affinity for silver. This last fact, indeed, is not new, for it was shown by Professor Donny, in an early volume of the Society's Journal, that the quantity of iodide of silver which the fixing bath would take up was altogether smaller than that of chloride of silver, and that when iodide of sodium had accumulated in the bath its solvent action became almost suspended.

COMPOSITION NOT PATCHWORK.

By H. P. Robinson.

That facility in communicating one's ideas with lucidity is a qualification advantageous to its possessor few persons will be disposed to deny, especially if, like the writer, its absence somewhat involves them in a dilemma similar to that in which I at present find myself placed.

That the animadversions to which my paper on *Printing Photographic Pictures from several Negatives*, read before the Photographic Society of Scotland, and published in your number for 2nd April last, have given rise are not well founded, I am thoroughly convinced; but, from absence of the happy knack possessed by some more fortunate in this respect than myself of saying the right thing at the right time, I may, perhaps, find some difficulty in rebutting them. No sensible man would feel annoyed at, or think it necessary to reply seriously to, jocular criticisms like those proceeding from your correspondent, Mrs. "Penelope Ann Spriggins," but would be rather inclined to join in a good-humoured laugh against himself. With regard to an article which appeared in your last issue, from the pen of Mr. A. H. Wall, under the title of *Composition* versus *Patchwork*, the case, however, assumes a somewhat different aspect, because Mr. Wall's opinion upon such a subject is entitled to consideration; and though his remarks are entirely free from offensive personality to myself, but rather directed against the practice of photographic composition in the special manner that I follow and conceive to be a legitimate occupation, I feel that, as they were elicited by a paper of mine, I am in some measure called upon to make some rejoinder. I shall, however, do so very briefly, leaving my justification in your hands, because it is partly owing to your commendation of my first effort in this direction that I was induced thus to turn my attention to it, and this principally from pure love of the art.

I am sorry Mr. Wall objects to composition. He is a gentleman for whom I have the greatest respect, and, from what I have

hitherto seen of his writings, I thoroughly believe in his perfect good faith. I do not expect him to admire my works: I am well aware they are full of faults, but they must be put down to my want of skill. I beg to offer the following remarks on Mr. Wall's objections:—

Mr. Wall should know that at least *two* of the "barbarous wielders of the scissors" have "touched the pencil under the guidance of a cultivated taste," and that they know all about the difficulty of imitating "that imperceptible boundary of vision which we call the outline;" and, having previously encountered this difficulty in many years' experience as painters—for some photographers learned art before they used a camera—they know what is required, and are devoting their attention to its accomplishment. This done, I fancy Mr. Wall's principal objection will be removed.

Rejlander can join the portions of a picture so that *I* cannot find the outline, therefore I cannot see the application of the paragraph directed specially against the scissors as a tool to work with. I am happy to say that I can see my faults, or I should never improve.

Some writers hold that there is a "fault in faultlessness." In the *Curiosities of Literature*, Disraeli quotes Trublet as follows:—"The more there are *beauties*, and *great beauties*, in a work, I am the less surprised to find *faults*, and *great faults*. When you say of a work that it has many faults, that decides nothing: I do not know by this whether it is execrable or excellent. You tell me of another, that it is without any faults: if your account be just, it is certain the work cannot be excellent."

If I want a few yards of the top of a hill as a base for figures (as in *Nearing Home*), and if it suits me to make a *fac-simile* of a small portion of that hill in *real* earth and *real* vegetation in my garden, why should I not be allowed to do it? The same with the water in *Preparing to Cross:* would the "deception," as Mr. Wall calls it, have been discovered, if I had not myself revealed it? And, if discovered, where is the harm? I do not assert that it is a portrait of a particular hill or a particular river.

I maintain that I can get nearer to the truth for certain subjects with several negatives than with one. Witness the foreground and distance in the *Top of the Hill*—the one five yards from the camera, the other a mile.

How does Mr. Wall propose to take such a picture as *Fading Away*, including a natural sky, "with a good enlarging process, and a lens commanding a wide angle of view?" Again, let his models be ever so clever, how would he get thirty or forty of them to keep still at the same moment, to say nothing of expression, as in Rejlander's *Two Ways of Life?*

As to ridicule, we must, of course, bear it; but we can take some comfort from the progress of pre-Raphælitism, for many years justly laughed at for its crudities and bad drawing, as my attempts are laughed at for their "cruel cutting outlines," &c. Walk, however, through the Academy's Exhibition, and see how four-fifths of the pictures have been influenced by the works of the men who were scoffed at; and mark the progress from their first works to Hunt's picture, now exhibiting in the German Gallery. Now, I quite feel the immeasurable distance between the genius of Hunt and Millais and Rejlander's and my humble talent; but, *parvis componere magnis*, I do think that in years to come composition photography will have as much influence over the art as the pre-Raphælites have had over painting. Their faults have smoothed down, but are we not to be allowed room and time for improvement? Are our faults to be eternal? I quite believe the time will come when photographs will be admired more for their invention than their execution.

"COMPOSITION" versus "PATCHWORK."

By Alfred H. Wall.

Will you kindly permit me to add to my previous observations upon the above subject just a few more words, as, from remarks which have reached me from various quarters I fear that my purpose therein runs some risk of being misunderstood. Since the publication of the last number of The British Journal of Photography, a friend has very kindly called my attention to the paper read by Mr. Rejlander at the Photographic Society, in April, 1858, upon *Composition Printing*, in which he describes his very beautiful picture, *Two Ways of Life*. Now there is a very wide difference between the two papers by Robinson and Rejlander; but, although in my present voluntarily assumed position it is, perhaps, cowardly to shrink from expressing honest convictions because I respect the individual concerned, or fear misrepresentation, I shall excuse myself with one of our handy old apothegms, "comparisons are odious," and only advise all who have read but one of these papers to read the other, and *compare the two*.* Both of these gentlemen and myself have at heart the same object, viz., the advancement of photography; and I appeal to that sympathy which community of tastes and pursuits ought to originate to prevent, on their part, any misunderstanding of motives. I might not perhaps think it necessary even to do this had I not seen a letter signed "Fairplay," in the last number of your Journal, in which a gentleman, whom I have every reason to esteem and respect, has been traduced for speaking his mind in a manly and straightforward—but good humoured—manner. The epistle in question, however, having been written by a lady precludes further criticism.

Mr. Robinson will excuse me, I trust, in frankly stating that I consider his pictures are not artistic. More or less, all that I have seen lack pictorial excellence; and when I read this gentleman's paper I at once understood why they lack this most important element. He describes therein not "composition" printing, but a kind of "patchwork"—the mere *mechanical* process of "printing photographic pictures from several negatives," and nothing more—a process which, as he frankly enough confesses, "is so simple, that he never before thought it worthy a written description," but which he, nevertheless, appears to esteem highly, and think important.

I look at Mr. Robinson's pictures, and find hard, inelegant outlines, an absence of refinement in their execution, no very studious arrangement of light and shade as elements of breadth, &c., also a neglect of the rules of composition, which, before I read his paper, I was inclined to attribute to downright carelessness; but, having read it, I now perceive that he has given the scissors and paste-pot credit for qualities properly emanating from the study of art—or, in other words, followed the crowd of photographers in perseveringly or obstinately giving to their tools the credit which should have been won by their brains, and making a boast of qualities really and purely mechanical, instead of such as reside in the higher regions of the intellectual, the poetical, and the artistic.

Turning from this gentleman's pictures to his paper, I find the mechanical idea dominant, although disguised, transparently enough, under the name of art. He "*cuts out*" here, "*pastes on*" there, compounds artificial landscapes in miniature in his "small back yard," &c.; but he says nothing of "the conception of a picture, the composition thereof, with the various expressions and postures of the figures, the arrangement of draperies and costumes, the distribution of light and shade, and the preserving it in one subordinate whole." Mr. Robinson says encouragement should be given to "any efforts to advance art," and "to the attempts of the few who try to get out of the beaten track (failures though they may be);" and, if Mr. Robinson humbly considers himself as one of these few making this attempt, will he kindly consider me as a very unpretending, but bluntly-speaking friend, desirous, to the best of his poor ability, of lending him a hand; or as one fighting shoulder to shoulder *with* himself and our few good comrades, against the prejudices of photographers, the jealousies of artists, the dogmatism of critics, and the ignorance of the general public.

Rejlander's pictures are eminently artistic, and so was his paper. I have not the means of learning, otherwise than from his paper, his opinion of printing from several negatives to obtain one picture, but I should judge that he looks upon scissors and paste as *very* disagreeable necessities; and I find that, although he upholds "the right of the photographer to do as he likes with his own," he only does so while "*he sails not under false colours*." The reading of Rejlander's paper has been a source of much pleasure to me. It was such a luxurious novelty to find *a photographer* talk about "*glazing* over some parts with a sunbeam" to destroy the effect of "*too much crude light*;" of travelling about and going to bed with his darling work, during its progress, ever in his mind; of photographing his figures from a sketch, and popping his studious face under the dark cloth to measure proportionate sizes on the focussing glass; of regulating the pressure in his printing frames; and of that glorious process—which he calls "the sun painting"—by which he uses "*a few rays and pencils of light to just glaze over*" this or that figure, and—for he talks a good deal to his "mysterious agents" while at work—having said "thank you," adding, "now please to *paint* me the background behind them;" and, as the rays do his bidding, again commanding them to "sink one of those figures deeper in the shade," even up here and touch out there; taking care all the time (because such light as he uses works quickly) to move fast and guide it well, lest there should be marks from—"HIS BRUSH." I imagined the anxious and unwearying thoughtfulness, the scheming brain, and the high ambition of this

* See *Liverpool and Manchester Photographic Journal*, 15th April, 1858.

great but really unpretending photographic printer; and thought of the pompous airs assumed by some small ones, whose "high art" consists in putting the sensitised paper into a pressure frame, taking a nap, if they please, until the print is dark enough, and then—taking it out, as far as they and the printing are concerned, finished. Despite the plasticity of photography in such able hands as Rejlander's, he is evidently perfectly conscious of the real and important difficulties of this mode of composition printing, inasmuch as he says:—"It is evident that if art were employed to give it the finishing touches, it would be more consonant with what art requires, and equally evident that an abler artist, *with better means*, could do a better thing;" and I therefore opine that his opinion and mine were not so far asunder when, in my last communication, I said that a lens commanding a wide angle of view, with clever models, judiciously chosen accessories, and a good enlarging process, were the right tools for photographic composition pieces, and not the scissors and paste-pot.

I remember, when younger than I now am, a fellow-student came to me full of indignation with Turner, who had looked at his drawing that day and praised it highly, until he (the student) began to boast, in a tone of gratified vanity, that he had done it without erasing a solitary line, when the great artist turned on his heel with a curl of his lip, muttering, "Then rub it all out, sir—rub it all out, and begin again;" and, said my brother-brush, in conclusion, "What the deuce could the old bear mean?" "Perhaps," said I, "he meant that if you could do it so well without your india-rubber you could do it better with it." Now, I look upon the presence of scissors and paste as Turner did upon the absence of india-rubber.

The above would have concluded this communication, but I cannot resist the opportunity of adding some notice of a circumstance which has occurred since it was written. Sitting in my painting-room, there was brought to me a hard, small, slightly magnified, cartridge-looking affair in paper, directed to me, and bearing the following inscription:—"Mr. Rejlander's revenge for Mr. Wall's article." Now, if I had been a nervous, timid man, I might have thought of infernal machines, and hesitated to touch this "revengeful" article sent in reply to my own. As it was I opened it, and found—what do you think?—a block of wood to symbolise the material of which my head was "composed," in the opinion of Rejlander the revengeful! Well, there certainly was a wooden block, but it preserved from injury one of the most beautiful art productions of photography with which these eyes have ever yet been delighted, representing a fine intellectual head, with the calm majesty of martyrdom in its death-like expression, borne in the charger, by which I immediately identified it as being that of John the Baptist. While I possess this gem I shall never want a proof that photography has the power of dealing with the more ambitious efforts of aspiring art. Such "revenge" really "is sweet."

ON THE SOLAR SPECTRUM IN ITS RELATION TO PHOTOGRAPHY.

[Read at a meeting of the Blackheath Photographic Society, May 21, 1860.]

By T. R. Wheeler.

(Concluded from page 163.)

Before I proceed further with a detail of these experiments and their results, I may as well complete the history of photometers (mentioning incidentally the names of J. R. M. Fane and Silbermann, the latter the inventor of the heliostate, and of M. Claudet, an experimenter in the same direction) by an account of other photometers which have been from time to time suggested, such as peroxalate of iron, proposed by Professor Draper, and modified by Dr. Woods. It will be perceived that three distinct methods are recognised in the above description: the dry method, or simple exposure of a dry sensitive surface to the action of light; the moist, where a solution of a salt decomposable by light is employed, and the gaseous where a mechanical mixture of gases is submitted to light, and under such exposure a chemical combination occurs, together with the formation of a definite chemical compound. Where a solution of the peroxalate of iron is employed, which is naturally of a golden yellow colour, and in the dark may be preserved unchanged for a great length of time; after exposure to solar, or even to artificial light, decomposition takes place, a pale yellow precipitate of protoxalate of iron falls down and carbonic gas is evolved. The amount of this may either be estimated by weight or volume, or by the weight of gold or silver which the solution *after exposure* is able to precipitate.

The following equation will show the nature of the arrangement just described:—

$$Fe_2\,O_3,\ {}_3\,C_2,\ O_3 = {}_2\,(Fe\,O,\ C_2\,O_3) + {}_2\,C\,O_2.$$

Besides the peroxalate of iron, Mr. C. J. Burnett suggested, in 1858, an actinometer, in which the fluid to be acted upon by light consisted of the oxalate of uranium in solution, and the carbonic acid gas, generated by its decomposition impinged upon a column of mercury, which rose according to the pressure in a bent tube, to which was attached a graduated scale—an ingenious and simple arrangement, and one infinitely more easy of application than that employed by MM. Bunsen and Roscoe, viz., the tithonometer of Professor Draper, but infinitely less sensitive where very great accuracy is desired.

The chemical ray, then, as has been shown, having a synthetic action upon a mixture of chlorine and hydrogen, in direct proportion to its energy and amount, it is stated by Professor Draper that the light of the electric spark, whose duration does not exceed an infinitessimal fraction of a second, will cause explosion. MM. Bunsen and Roscoe availed themselves of the fact, by submitting a mixture of these gases (prepared from hydrochloric acid by electrolysis, or the decomposition of the acid by voltaic electricity, for the purpose of avoiding error) to a known quantity of light, estimated by comparing the illuminating power of a ray reflected by a Silbermanns' heliostate through a small aperture into a dark room, with what they called a standard flame, such as the ignition of a jet of carbonic oxide of a given size produces at the distance of a metre, or 39 inches, in one minute of time; and that they called one unit of chemical action, and comparing the amount of combination of the chlorine and hydrogen, to form hydrochloric acid, which was found to take place, with many results, established the relations. I shall presently detail between the light energy in various parts of the world. The fraction of the sun's rays being calculated, it follows that the whole amount of light emanating from the sun can be found; if allowed to shine upon the instrument directly, the action would be too rapid, and the instrument shattered.

I must now quote Dr. Roscoe's pamphlet almost *verbatim*, although I condense the matter of his report.

The day chosen for experiment must be cloudless, and the observations continued from sunrise to sunset.

It would appear that the actinic power increases in inverse proportion to the column of air through which the sun's rays have to pass. In other words, the light energy increases from the time the sun clears the horizon until it has attained its meridian height, and afterwards decreases in something like the same ratio, so that there are two periods in each day when all things being equal the same chemical action is observed. "The rays, in passing through the air, are extinguished or absorbed as light; and as the sun rises above the horizon, the column of air being lessened through which the solar rays have to pass, more of the direct rays reach the earth."

The law by which this absorption of rays obtains can be deduced experimentally; and therefore, if the action of the sun at any given height is known, its action at any other height can be calculated.

This calculation being made, agrees very remarkably with the results of observation. I cannot reproduce *verbatim* Dr. Roscoe's tables, but I may be permitted to relate the general issue of his experiments conducted at Melville Island, Rejkiavik, Iceland, St. Petersburg, Manchester, Heidelberg, Naples, Cairo.

These experiments gave the light action in four forms, viz.:—

1st. The action of direct sunlight in degrees of light.
2nd. The same of diffuse daylight in degrees of light.
3rd. The same of total light in degrees of light.
4th. The action of total light in light metres.

In the latter it was found that while in Melville Island the total chemical action effected by the solar rays from sunrise to sunset, of the vernal equinox, was at

Melville Island	1306.
Rejkiavik	2324.
Petersburg	2806.
Manchester	3625.
Heidelberg	4136.
Naples	5226.
Cairo	6437.

Or five times as great, in round numbers, at Cairo as at Melville Island, and probably would be found even greater in situations nearer the equator.

I had hoped to have been able, with the kind assistance of your President, to have exhibited this evening the action of the prismatic spectrum, obtained by passing a ray of light from the poles

of a Grove's battery through a prism, upon a surface of sensitive paper, or upon a wet collodion plate. You would have then had ocular proof of the intensity of action exhibited by the various rays. As it is, I must simply state as above, that it will be found greatest at the violet end of the spectrum, and least at the red.

Now, gentlemen, it is impossible to over-rate the importance of investigations like these. To the casual observer they present a few bubbles of gas rising to the surface of a fluid—a column of mercury rising or falling the fraction of an inch—a surface of paper more or less discoloured. To the deeper thinker—to the more profound inquirer—they afford an insight into one of those agencies by which the Great Creator is pleased to regulate and control what we see round us in his Creation. In fact, we recognise in light one of

> "The vast magazine of means,
> Formed at His word, and ready at His will."

It is difficult to say where the action of light really ends. The succession of the seasons, the growth of plants, as also the distribution of those cognate groupings which constitute the flora and fauna of countries,—all have a relation, and that a direct one, both positively and negatively, with this influence; and last, not least, the physical state of mankind, and no small part of what we call hygeine, depend directly upon it. Is it going too far to say that his moral nature is likewise, in any way, under its influence? Certain it is that the human race becomes deteriorated in proportion as physical laws are neglected or permitted, and it is very hard to determine at what precise point one influence ends and another begins. Do not misunderstand me in this.

The nature of the influence which light exerts in a substance either nascent, in a state of change, or so loosely aggregated that a change may be effected in it, being molecular, leads me to say a word upon the etiolation of plants.

These, it is well known, when grown in the dark, do *not* develop the qualities and proximate principles which belong to them as members of natural orders, but are found bleached white, and devoid of colouring matter and chlorophyl. What is this but the absence of that chemical force by which molecular aggregation is regulated? It matters not whether it be the blue ray or the golden which is concerned in the agency, it is clear that an action is absent in the one case which is present in the other. Combinations of carbon and water are found indeed *without* light, but *with* it are developed those more complex arrangements which are deservedly called "organic," inasmuch as they are generated by the stimulus and under the direct control of vitality. So that it is not jumping to a conclusion, but deducing as a necessary consequence from the foregoing reasoning, by stating that there is a relation, and that a very intimate one, between light and vitality, either as cause and effect, or, at all events, as an accessory fact.

To such a point have those researches been pushed, that MM. Bunsen and Roscoe, not content with measuring the actinic force in various parts of the earth, have been actually enabled to apply that measurement (roughly estimated, indeed, but still approximately true,) to the relative chemical power of light in the various planets forming part of our solar system. Admitting its immense influence upon the organic life developed in this terrestrial globe, and admitting some analogy to exist between members of a system where harmony, order, and co-ordinate relation appear transcendant, is it presumptuous, and is it wholly unprofitable to speculate upon the states and conditions of other orbs which have this community of light influence superadded to the universally pervading law of gravitation?

True, such speculations can never wholly be verified. Still, whatever enables us to make large generalisations, by establishing relations between scattered members of a vast group, elevates the mind of man, and, raising him far above the things of time and space, give him *glimpses*—a faint perception—and that the only one he can hope for in his mortal condition, of the tremendous questions of infinity and eternity.

ON THE APPLICATION OF PHOTOGRAPHY TO SCIENTIFIC PURSUITS.

By the Rev. F. F. Statham, B.A., F.G.S.

[Read at a meeting of the South London Photographic Society, May 17, 1860.]

(Concluded from page 159.)

I come next to speak of the application of photography to *medical science*. In what way can this useful art be rendered subservient to the advancement of this all-important subject? Why plainly by multiplying accurate copies of every varying form of disease, by enlisting the camera as our most faithful transcribers of the successive changes of symptoms in sickness, and of the difficult presentments of morbid anatomy in general. At most of our principal hospitals the necessity of preserving a correct record of peculiar forms of disease has led, I believe, to the retention on the permanent staff of the institution of one or more experienced draughtsmen and modellers in wax who may be at hand to copy from the living patient, or the dissected corpse, any appearance calculated to throw a light on the origin or progress of the malady, or to form a useful object for study in the future treatment of similar classes of disease. Now, I cannot but think that even here the marvellous rapidity of execution, and the minute fidelity of the photographic picture, give it an advantage which would render the appointment of a photographer also a most desirable addition to every hospital staff; for very frequently the changes in the progress of disease are sudden and striking, and before an accurate copy of them could be made by hand the patient may die, or a successive change may come on, and so the rare opportunity be lost of chronicling some evanescent but important feature of the particular case. With the aid of the camera I can contemplate the time when every varying phase and form of disease will be as familiar in illustrated works or nosology as the real appearances now are to none but our most experienced physicians and medical men. The time of the student will not be wasted in reading long and minute descriptions of that which after all is so difficult to describe, but he will be referred to the real thing, or rather to that which is next to it, viz., an accurate photograph capable of being examined microscopically, and so furnishing almost the same advantage as would be conferred by a sight of the suffering patient on the hospital bed. But beyond this I conceive that photography may hereafter be pressed into the service of medical science for the purposes of *consultation* in cases of danger or difficulty. An accurate photograph of one afflicted with any serious malady could not but be of the utmost value to any skilful physician in forming a judgment of the case, if from the distance at which the patient might be residing it should be impossible or inconvenient for him to attend personally, or if the means were not forthcoming to pay the very heavy expenses of a distant county visit. Or perhaps having once made the visit, a photograph of his patient forwarded at intervals by the resident medical man, or by some intelligent member of the family, with a written account of the attendant symptoms, would amply suffice to one well acquainted with the usual course of the disease to enable him to prescribe accordingly, and thus reserve his time and energies for other sufferers. And this would be no small gain to society at large, for many might in this economical way have the advice of the heads of the profession in any complicated form of disease who are now deterred by the expense from applying to any other than their own neighbouring practitioner, the very multiplying of whose avocations may have prevented him from studying sufficiently the especial complaint to the care of which the physician most usually consulted has devoted the greater part of his life. In the study of *comparative anatomy* also, where the exact relation between the several parts of the skeleton is so necessary to be preserved, the accuracy of the photographic representation cannot fail to be of the highest value. The minute details of the animal frame, so difficult to copy exactly, and requiring scientific skill on the part of the draughtsman, may henceforth be faithfully represented by almost the humblest experimenter in photography, and thus may we hope that the immortal labours of Hunter, of Cuvier, and of Owen, now locked up in works of formidable dimensions and of costly price, may soon be popularised and brought within the reach of the great body of readers through the instrumentality of the camera, as the cheapest and most effective medium of illustration.

In aiding the progress of *architecture* the advantages derivable from photography are obvious. Views of existing edifices remarkable for grandeur of conception, for beauty of execution, or for comprehensiveness of design, may readily be multiplied with the utmost fidelity and with the most artistic effect. The progress of decay in many of the now crumbling memorials of the genius of a past age will be, so to speak, arrested for a time. The photographer will point his camera at each pinnacled niche or floriated doorway; he will take his sun-painted sketch of each figured corbel or grotesque gurgoylé; and, in fact, carry away in his portfolio every nice detail of the architectural design, long before Time, with his destructive hand, shall have had the opportunity to mar any more of the beauty of the original; and when future ages shall be wishing to picture to themselves the appearance of this or that abbey or cathedral long since crumbled to decay, in all its pristine grandeur, they will thank Providence for the perfection of photography in the middle of the nineteenth century, and will know at least how all the most renowned architectural remains looked

about that period when Time had as yet dealt leniently with most of them, and when a love for art, begotten anew by the means of preserving its records photographically, had sprung up with youth-like vigour among the inhabitants of our favoured land.

Henceforth there can be no need for bringing at a heavy cost sculptured effigies from Italy or Greece, chiselled obelisks from Egypt, or arrow-headed inscriptions from the mounds on the Assyrian plain. A few samples will suffice to give a general idea of the whole treasure stored up, and photographic copies of every object possessing public interest may then easily be procured, by the careful examination of which the entire history of the ruins may be read, and a correct estimate be formed of the value of the whole. At the present moment, it would scarcely be saying too much to assert that the pencil of the sun is gradually painting for us a representation of every architectural monument throughout the world calculated to awaken emotions of pleasure from its associations with the past, or from its undoubted existing artistic beauty. Our indefatigable countrymen are ascending the Nile, tracing the course of the Zambesi, navigating the Ganges, the Yang-tse-Kiang, the Mississippi, climbing the Alps, the Andes, the Himalayas, in fact wandering to every region of the habitable globe in search of the beautiful and the picturesque, and sending home for our inspection at our quiet fire-sides the fruits of their labours, in views from all the principal capitals of the world, in scenes memorable for past grandeur or glory, in glimpses of nature unwitnessed before perhaps by mortal eye, in sketches of everything that has borne the impress of human genius or skill, whether in the ruins of the sculptured temple, or the mutilated fragment of Runic carving, such as the ancient cross from Kirk Braddan, which I produce in illustration of the remarks I have made. And I think we may venture to affirm that already a perceptible improvement in the public taste has sprung up from the contemplation of these multiplied proofs of existing or past excellence. Unsightly public buildings are not quite so popular in this country as they were wont to be in the days gone by. We have been rendered so familiar with the striking features of the continental cities by the aid of photographic sketches, that we are beginning to think at least whether it is not possible to add to the architectural beauty of our own. We are gradually training ourselves to inquire whether we cannot blend the artistic with the useful in our plans for public institutions. The capitalist, who is about to build a villa or to lay out a new street, is beginning to think of the figure it will cut when photographed and exhibited for letting or for sale in the auctioneer's window; and he is perhaps induced by this consideration to employ an architect and bargain for a little display of ornamental skill, instead of confining himself as heretofore to the four solid square walls, the inevitable row of ugly chimneys, the mathematically parallel doors and windows, and the circular grass plot to pattern. But independent of the gradual improvement of the public taste in architectural matters, traceable, as I apprehend, very largely to the multiplied copies of artistic excellence produced of late by photographic agency, the architect may fairly look to the camera as one of the most useful adjuncts to assist him in the performance of his peculiar labours. By it he may, at little expense or trouble, enlarge or diminish his plans, without the aid of scale or compass. He may ascertain, if at a distance from the scene of operations, how the work of building is gradually progressing, under the charge of a clerk of the works. Nay, if the necessity of taking down and rebuilding the same edifice should exist, he may (as was lately done in America) number every stone and brick, and then photograph the building so numbered, and erect it again from the photographed plan, precisely as it was originally constructed.

But I must pass on to other applications of the photographic art. *Civil engineering*, *mining works*, and *military operations generally*, have been largely indebted already, and will, I venture to predict, be hereafter still more so, to the assistance of the camera. The drawing of plans for railways, bridges, and roadways, must obviously be greatly facilitated by correct sketches of the localities through or over which they are designed to pass. I am informed on good authority that, during the construction of the Grand Trunk Railway of Canada, it has been a matter of great advantage that the chief engineers in this country should have been able, so to speak, personally to superintend the work, almost without leaving this country, by the inspection of carefully-executed photographic plans, as it has been gradually approaching completion. And we are all familiar with the beautiful views of the Great Eastern, taken during her various stages of advancement by the aid of the camera, by which we can gradually trace her emerging from her giant carcase of iron ribs to the beautiful symmetry and perfection of her complete design. To illustrate the use of photography in this branch of science, I exhibit a view of the great Laxey Water Wheel, in the Isle of Man, by a brief examination of which any unpractical man would, by a few words of explanation, gain as complete an acquaintance with this masterpiece of mechanism as by an inspection of the actual wheel itself. In mining works it is sometimes of the utmost importance to convey to the body of directors the gradual progress of the erection of machinery, or a correct view of the appearance of a particular lode, or perhaps even a sketch of the position of the mine itself; and here again photography comes to the rescue, and furnishes a representation which may be depended upon for its fidelity, as conveying neither more nor less than the absolute state of things could warrant. In military operations the camera is invaluable for taking views of fortifications to be attacked, chronicling the effects of fire upon breaches, giving accurate transcripts of the nature and difficulties of any line of route to be forced, and perhaps even telling tales, by one momentary glimpse from a balloon, of the effective force which may be expected in the field, or revealing the whole plan of the campaign from a chance copy of a despatch, stolen by the aid of a sunbeam from a sleeping aide-de-camp's sabretache. In addition to which, we must not forget that the photographic records of past military struggles are not without their value to the student of strategetic science, and that plans of dismantled and vanquished strong places may still be useful, as offering warnings against the blunders of the past, or hints of improved modes of attack in case of future hostile operations. Fenton's series of views of the Crimean campaign will abundantly illustrate the force of my remarks, and prove, I doubt not, useful plates of instruction to those anxious thoroughly to comprehend the nature and the difficulties of that fearful struggle.

In *natural history* generally the appliances of photography cannot fail to be of the utmost value. *Zoology* will rejoice as it sees pictures of birds or animals, hitherto unacclimatised in this country, accurately delineated with all the peculiar features of the originals. *Botany* will be advanced by the easy identification of every form of vegetable life in all its minuteness of perfection by the aid of the camera. *Mineralogy* will be indebted to it for accurate copies of its choicest specimens, some of which crystallise in such complicated groups as to be excessively difficult of imitation by any other means; and the works of nature in general, such as gorgonias, sea anemones, the infinite varieties of coral marine-algæ, sponges, echinites, and other forms of animal, vegetable, or zoophytic life, will be easily represented with the assistance of photography, when before weeks and even months would have been consumed in making accurate transcripts of them. *Astronomy* already owes a deep debt to photographic art. By her aid the moon has been compelled to lend her own light in order to furnish faithful portraits of herself; the sun has, I am assured, recorded the passage of spots across its surface, and the exact appearances of a partial eclipse, and the cometary bodies have been made to leave the impress of their faint light upon the sensitised paper. It will not be presumptuous to predict that all future astronomical phenomena will be rendered more definite in their teaching by the increased facilities which the camera will afford for recording minutely their various phases, and perhaps even in the case of transits, viewed from different parts of the earth's surface, the application of photography may enable us to attain a precision and to multiply our observations to such an extent as to be of the utmost importance to the advance of astronomic truth.

ON TRANSFERRING COLLODION NEGATIVES TO WAXED-PAPER.

By M. Toulouse.

This process will be found very useful and convenient, inasmuch as it enables the travelling photographer to dispense with the greater part of his heavy, bulky, and fragile supply of glass—the constant source of anxiety and trouble in landscape photography. The negatives resulting from each day's operations can at night be transferred to waxed-paper; and when the glasses are cleaned they can be used day by day for the reception of fresh negatives. Some hundreds of transfers only occupy the space of a dozen glass plates, while the weight is reduced to a minimum.

The method to be pursued is as follows:—Take the collodion plate, unvarnished, and lay it on a flat board, then with a rule and a sharp-pointed knife cut through the film all round the edge, taking care not to damage the picture. Then take a sheet of positive paper and moisten it with water on both sides, by means of a soft camel's hair brush; lay the paper on the collodion, and

press it in every direction with a glass triangle, driving out completely the air and water from between the paper and collodion. To make sure, cover the moist paper with another piece, but dry, and press it gently down. When it is supposed to have become adherent, raise one corner, and if the collodion comes away from the glass lift it carefully. Sometimes one corner will not release the collodion, therefore if the first tried fails to do so, the other corners may be tried in succession. When the collodion film is completely detached from the glass, of course adhering to the moistened paper, lay it smoothly on a flat board, collodion uppermost. Then take a large flat camel's hair varnishing brush, and dip it into a solution of gum arabic, of the consistency of syrup, and cover with it the entire surface of the collodion. Then take a piece of waxed-paper cut a little larger than the collodion film, and lay it down carefully upon it, and press it equally all over with the glass triangle, dipped in water to prevent it adhering to the paper. When it is evenly spread, go over it with a piece of clean damp (not wet) sponge, to remove any gum that may be upon it, and place on it two or three folds of blotting-paper and cover it with a piece of glazed cardboard, fixed at the corners with pins. Then with a wooden roller go over the surface of the cardboard with a steady, even pressure. This done, take off the mass and turn it over on another board; the positive paper will now be uppermost. Then fix to the board with pins the waxed-paper, blotting-paper, and cardboard, and lift one corner of the positive paper; if the collodion film does not adhere to it, but remains attached to the waxed-paper, lift the positive paper slowly and carefully, and the collodion film will be found transferred and adherent to the waxed-paper. If such should not, however, be the case, damp the positive paper again, and in a few minutes repeat the attempt, when the collodion film will probably be found adherent to the waxed-paper. It is better to leave the waxed-paper on the blotting paper to dry, pinning round the borders four strips of cardboard, to keep it flat and smooth.

The negatives thus transferred are sufficiently transparent to yield good proofs, devoid of that extreme sharpness so prejudicial to artistic effect. To ensure success, we must take care that the collodion is of good consistency, neither too thick nor too thin—a point that can be best determined by experiment. The negative must not be varnished with the application of heat: a varnish applied cold does not prevent the transfer. The developer has no influence upon the result: either pyrogallic acid or sulphate of iron may be employed.—*Cosmos.*

STEREOGRAPHS.

Picturesque Scenery in the Vales of Tweed, Ettrick, and Yarrow, photographed by W. RODGER, *Montrose.*

WE wonder whether it would be possible for any photographer, armed with camera, tripod, and "ammunition," to pass within a moderate distance of the home of the great novelist without making a capture of the counterfeit presentment of it. Certainly we have seen as many different illustrations of ABBOTSFORD as there are months in the year at the least; and no wonder, for apart from its associations, which would be enough to redeem a bare brick wall from the charge of want of interest, it is well worthy the attention of photographers and other artists for its own intrinsic merits as regards the picturesque.

In the series before us we have three to notice, viz., No. 14, a view taken from the Galashiels Road, which gives a better idea of its exact position than any other we have seen. Located on the banks of the Tweed, and therefore in a valley, we perceive by the illustration before us that it is at the base of a fine, wooded slope, across which are seen the tops of the distant mountains, while the river stretches and winds far away on our left. In the immediate foreground is a stubble field, in which is a group of about a dozen farm labourers, male and female, some seated, some standing, but all apparently interested in something in the far distance. Although the foliage in this slide is perhaps a little too dark, it is unquestionably an admirable study for the landscape painter, as well as a welcome addition to the stereoscopic collection. In No. 15, a view of ABBOTSFORD FROM THE TWEED, the natural clouds add very much to the effect, being more heaped in rolling masses than in the preceding instance; but, though these indicate that the exposure must have been very short, yet it is evident, from the appearance of a silver birch tree in the centre, that a stiff breeze must have been blowing at the time, its ever restless foliage being somewhat indistinct, while that of some sturdier members of the vegetable kingdom on the left is tolerably well defined, though they distinctly show from their aspect the influence of the wind. In another specimen, No. 15 B, taken from the same spot, the masses of clouds are absent, but a bare-legged urchin is seen wading in the stream not far from the spectator.

HAINING HOUSE, near Selkirk, No. 10 A, is a very pleasing study, being a pretty combination of wood, water, and figures. On a point of land, around which the stream sweeps in a graceful curve, the house, shaded and backed by many stately trees, is situated. The near bank of the stream, seen across some low bushes, is fringed with pliant rushes, from amongst which a boat is being pushed off by a gentleman standing in the bows, assisted by another seated amidships, using an oar, while a third, standing on the bank, is waving an adieu.

YAIR HOUSE, No. 19, is an old fashioned though not picturesque structure, surrounded on three sides by a mass of magnificent forest trees, one splendid specimen of which is seen on the right, close against the river's bank. Good, substantial, pleasant comfort is the idea suggested by this specimen.

NEAR NEWARK CASTLE, on the banks of the Yarrow, is a slide of a totally different stamp; flat and poor it looks *out* of the stereoscope, but *in* it—"what a change comes o'er the spirit of the scene." No longer flat, no longer poor!—but rich in half-tone, richer still in beauty; the eye ranges down a picturesque grove of trees in full leaf, the branches of which interlace and chequer the vista through which the tranquil waters of the river and the wooded slope of the opposite bank are discerned. In the immediate foreground are the trunks of a couple of gnarled oaks, the bark of which is seamed and clothed with patches of lichen; farther on is the stem of a noble fir tree, then more oaks, while the long grass, cut by the pathway, brushwood, and stream, combine to make up a truly charming *tout ensemble.*

EVENING.—View taken from Selkirk Bridge, No. 13, is an effective study for the artist—the casual observer will not appreciate it. Near the spectator is a solitary figure, probably a gamekeeper, with a gun, standing in a turnip field, by the roadside. Across another extensive field are seen a few houses and farm buildings, with a plantation on the left, the background, consisting of a long slope of moorland hills. But, oh that sky! What a charm it has! How it lights up the outline of the hills! What a calm, soft light it sheds upon the landscape, which, though next to nothing in itself is glorified by the lingering smile of departing day!

MILL OF FAIREYLEE, on the Tweed (No. 16), though a capital subject, and full of all that goes to make up the picturesque, is a trifle under-exposed and over-developed. The tree is too dark and the water too white; but the rocks are sharp and bold, and the water-wheel just where it should be.

FOULSHIELS, the birthplace of Mungo Park (No. 5), though only a cluster of thatched cottages against the hill side, nevertheless composes into a beautiful subject. Located at the bend of the high road, with a by-road passing round the cottages—plantations on the right and left—a field in full crop in front and one quite fallow behind—the base of one extensive hill on the right, and the summit of another in the distance—a very pretty effect is produced with very moderate means.

With this we must close our notice of the series; but amongst a few miscellaneous slides we must mention one, called *The Game at Marbles*, where, in a back garden, two boys are busy over what in our school days we knew as "shoot in the ring," while a disconsolate-looking little lassie is seated on the window-step, appearing very much as if she would like to join in the fun, but felt doubtful of her reception.

We cannot close without intimating that, judging from the specimens before us, Mr. Rodger is a skilful operator, a capital printer, and has the happy knack of selecting judiciously his "point of view."

NEW DRY COLLODION PROCESS.

By M. PESCHARD.

COLLODION.

Ether	60·00	parts.
Alcohol	40·00	"
Gun cotton	1·60	"
Iodide of cadmium	1·20	"
Bromide of cadmium	0·02	"
Pure rosin	1·00	"

The rosin is added when the other ingredients are dissolved. Then add thirty drops of the following solution:—

Alcohol	2 drachms.
Liquid balsam of Peru	1 drachm.

Leave the mixture a couple of days to settle, then filter through cotton.

SENSITISING.

Sensitise in a neutral silver bath of the strength of eight per cent. (thirty-five grains to the ounce); next wash the plate under a light stream of water, place it to drain, dry upon folds of blotting-paper, and preserve in a box lined with black paper. The plates will remain in good condition for several days. The plate should be washed with distilled or rain water boiled and filtered.

DEVELOPING.

Water	3 ounces.
Pyrogallic acid	4 grains.
Citrate acid	4 ,,
Alcohol	1 drachm.

Previous to developing, wash the plate carefully so as to moisten it all over; then, without loss of time, pour over it the above developing solution, repeating the operation three several times; then add to the developing solution collected in a measure a few drops of solution of nitrate of silver (four per cent.), and continue pouring it off and on until the development is completed. The developing may be deferred two or three days after exposure if required.

When the plate is washed, it may be fixed with hyposulphite of soda, strength thirty per cent.

Meetings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The first anniversary meeting and *soirée* of this Society was held on Thursday, the 21st ult., at the St. Peter's School Rooms, Walworth.

The room was tastefully decorated with flags, wreaths of flowers and leaves, and numberless articles of interest and novelty were placed, for the inspection of the members and visitors present, upon tables ranged along the sides and centre.

Messrs. Horne and Thornthwaite exhibited an ingeniously-contrived optical instrument, called the trocheidoscope, for displaying various combinations of the prismatic colours; some stereoscopes with a number of beautiful transparent slides, and microscopes.

The London Stereoscopic Company contributed a set of their newly-published photographs of American scenery, which were very greatly admired.

Messrs. Cotton and Wall contributed a collection of photographs for albums, others coloured in oil, and some untouched.

Messrs. Squire and Co. contributed a variety of new and improved cameras for out-door photography, and one of Leake's dark tents, the simplicity and convenience of which, combined with its singularly portable character, was highly praised.

Messrs. Shepherd and Co. sent a portable camera of a very efficient description, &c.

Mr. G. W. Simpson brought some specimens of his beautiful alabastrine process, coloured and non-inverted, which won no little attention.

Mr. Burr, F.R.A.S., exhibited a beautiful collection of photographs under the microscope, one showing the moon as produced by that luminary's own rays, and photographed by Mr. De la Rue with his thirteen-inch reflecting telescope; also a number of photographs of lunar scenery in the magic lanthorn, of which he gave a most interesting and concise explanation.

[For the courtesy, kindness, and attention of this and of other gentlemen, whose able co-operation was so generously given, the committee desire to express their grateful thanks.]

Mr. Garnham showed numerous curious and interesting microscopical results, the exhibition of a living daphnia attracting great attention, the beating of the heart and internal workings of the body being clearly seen.

Mr. W. Clark exhibited his new binocular camera.

Mr. Tear brought forward a stereograph taken by the Fothergill process, but for which, as a preservative agent, he had taken a little of the sago which had just then been prepared for "the baby." The resulting picture was very intense, and displayed good half-tone.

Mr. T. Clark displayed a variety of photographs in the magic lanthorn. For many of the slides so exhibited, thanks are due to Mr. Hannaford and Mr. Ackland.

Mr. Noldwritt exhibited some photographs coloured in oil, a globe of the moon, which illustrated very clearly Mr. Burr's description of the lanthorn slides; several interesting curiosities from India, stereographs, &c.

Mr. Wall contributed a large collection of photographs, stereographs, engravings, and curiosities.

Mr. G. Shadbolt also contributed some photographic albums, and a large collection of beautiful stereographs.

The Rev. F. F. Statham, President, sent a collection of interesting relics and curiosities from the East. Other friends also aided with various objects of interest, amongst which were some *fac-similes* of drawings by Raphael, photographic portraits, landscapes, and stereographs, &c., contributed by Messrs. Newman, Forrester (Crowquill), Mills, Howard, Smith, and others. A fine vignette picture of the *Head of John the Baptist in a Charger* was handed round by Mr. Wall, as the production of Mr. Rejlander.

Mr. Moule exhibited his apparatus for night photographing, and several specimens produced thereby.

The Rev. F. F. Statham, B.A., President, in addressing the meeting, said, that they had assembled on that occasion in the St. Peter's School Rooms, instead of their usual place of meeting, on account of the increased space thereby afforded for exhibiting the objects now before them. They were compelled to go shortly into business matters, but he would promise the ladies they should not long be detained in listening to the formal part of the evening's proceedings. He would, in few words, announce the state and the success of the Society, and the Secretary would then read the annual report, after which every endeavour in their power would be made to cause the evening to be spent agreeably. He need say but little on behalf of photography, in which the ladies were perhaps the most interested as presenting to them faithful likenesses of those who were most dear to them. But even as a gentleman he was indebted to photography for the pictures of his wife and children, so that even death itself could not take away from him those features which he so loved. They could see from the specimens before them in how many ways photography had been made interesting and of service. In various parts of London societies had been formed, and those living in the neighbourhood of Walworth would almost have been considered Goths and Vandals if they had not instituted this Society. The Society had not been in existence very long, this being its first anniversary, but he trusted that it was firmly established, and that it would find numerous supporters among those residing in the neighbourhood. They had among them several gentlemen of considerable talent, and he trusted that they would continue to meet to spend many evenings together in such an innocent enjoyment. He thought a man had a right to have a "hobby;" and he did not see why, if he took a fancy to photography or electricity, his apparatus was to be poked up in a back attic instead of being kept in the parlour. In order to avoid that, it was necessary the ladies should be led to take an interest in their husband's pursuits, and for this purpose ladies were invited to become members of the Society. In order to induce them to join, several rural excursions to places within a short distance from London had been planned for the ensuing few months, when he trusted the weather would be more propitious than it had been latterly. Of course the ladies would be placed about the scenes to be taken, and they would form certainly not the least attractive feature in the views. He trusted they would all feel that the Society was deserving of encouragement, and would do all in their power to induce their friends to become members of it. Whilst at one end of the room, food for the mind was supplied, they had taken care that at the other end refreshments of a more substantial character for the body would be administered. He would now call upon their diligent and energetic friend, Mr. Wall, to read the annual report.

Mr. Wall then read the following report for the past year:—

FIRST ANNUAL REPORT OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

In obedience to Rule 9, your Committee proceed to lay before you this their first annual report. The present aspect of the Society is decidedly promising, and we may congratulate ourselves on the apparent surety of its foundation. Our members are not large in number, but we have a very fair share of vitality, and contrive to be active in our proceedings. The meetings have been tolerably well attended; but we regret that several members, whose election raised sanguine hopes, and whose names won us public respect, have not yet "put in an appearance" on our behalf; still we console ourselves with the credit of contriving to do well without them, and the earnest hope that we may do better *with them* in the next session.

The South London Photographic Society sprang into existence on the evening of May 10, 1859, at a meeting convened by public notice, and by your present Secretary, which was attended by Messrs. G. Shadbolt, W. Ackland, F. Howard, A. Hervé, and J. C. Leake. A provisional committee was formed for the proper organization of the Society, and the first public meeting was held on the 9th of July following.

The papers read at our monthly meetings are as follow:—

Truth in Art Illustrated by Photography, by H. L. Keens, Sen., a gentleman, not a photographer, who was an artist before photography was known, and whose sympathies might naturally be supposed to be with the traditions of art, came forward in this, and one other paper, as the champion of Photography, upholding its truth, asserting its power, and appealing to it in refutation of the principles advocated by a modern vicious school of painting.

Practical Hints upon Positive Printing, by J. C. Leake, Jun.—This paper, by a very successful professional operator, affords an illustration of the real practical value of such societies as our own. Although containing hints of great utility, and evincing the result obtained by very great experience and practice, it advocated a process of printing and toning which is now generally known to be unsafe and unsatisfactory. The discussion which followed the reading of this paper was mainly instrumental in inducing Mr. Leake to abandon the old for the new alkaline gold toning bath; and as this gentleman provides portraits for a large number of customers, we may claim for ourselves the honour of having done some good service to the public in the increased permanency of their photographs.

The Difficulties of the Dry Processes, by W. Ackland, Vice-President.—This was another paper of eminently practical value, and the information it contained must have been of no little service in diminishing the chances of failure. The various difficulties were illustrated with specimens, as well as described; and, being traced carefully to their source, were accompanied with remedies which had been practically tested by the author himself.

Observations on Photographs in their Relation to Art, contributed by your Secretary, in which he endeavoured to point out the exact position photography occupied in regard to art, and to show that success in the former was largely indebted to a correct appreciation and knowledge of the latter; adding hints of a purely practical description to assist in producing results of a pictorial character.

On Recent Improvements in Photographic Apparatus, by W. Clarke.—In this the respective merits of the various cameras and other apparatus were described, and specimens exhibited.

Failures in the Wet Process: their Cause and Cure, by J. C. Leake, Jun.—The highly suggestive observations of a well-known efficient operator, who had encountered *and overcome* these difficulties, and the exhibition of about a dozen defective plates, could not but be valuable to the practical portion of our members.

The Iron-Printing Process, by M. Hannaford.—This, and several other short papers by the same author, were all upon infant processes of a promising and most important description, which offer a very wide field for experiment and research of a practical and philosophical description. We trust this gentleman may not let us want his really invaluable aid in bringing forward such papers in the coming session.

On Amateur Photography, by Frank Howard.—Our treasurer, in this excellent paper, dwelt with all the enthusiasm one might expect from a photographer so universally successful, on the delights of an art he had taken up in the purity of an amateur's love, although with a conscientiousness very characteristic of the man himself, he also pointed out, with the utmost precision, such shoals and rocks as beginners usually encounter.

On Certain Experiments with the Salts of Silver, by Mr. T. Clarke.—Although these experiments lacked the precision necessary to increase their value, they induce us to hope that this gentleman will continue others of the same practical description, if only that they may originate the discussions from which we all derive so much benefit.

On the Application of Photography to Scientific Pursuits, by the Rev. F. F. Statham, B.A., F.G.S., President.—This was an eminently interesting and highly exhaustive paper on a subject of great suggestive importance, reviewing the applications of the art to scientific purposes, and pointing out new directions into which it might be turned with highly advantageous results.

Photographic Jottings.—In addition to these more formal papers, a quantity of valuable information has been contributed under the head of "Jottings," being brief notes of experience on some special subjects of interest. For these we have been indebted during the session to Messrs. Hannaford, Ackland, Leake, Wall, and Martin. These little friends have been, and will doubtless continue to be, of the greatest importance, offering, as they do, a medium for the communication of facts not in themselves of sufficient importance to constitute entire papers, and a temptation to modest or timid members to embody a thought or incident of their practical experience, in a form so simple and unpretending.

The discussions, we are happy to add, have been numerous and animated, eliciting much useful information.

The portfolio's claims upon the generosity of members have not been neglected, but, like an importunate beggar, its continual cry is still—"give, give, give."

The Exchange Club has been duly organised, and several specimens are now in the folio for exchange. Members will be very gladly received, and it is not necessary that such should be members of the Society.

By an alteration in the rules, our usual recess will be converted into a series of outdoor meetings, intended for the benefit of beginners in the art, and for the purpose of exchanging in absolute practice hints which cannot be communicated with the same effect by mere words. Such meetings, it should also be remembered, will enable us to combine our experience, skill, and knowledge for the prosecution of various experiments of a practical character in connection with the pictorial, optical, and chemical elements of the art.

Numerous objects of interest have been brought forward at our meetings in the shape of specimens, apparatus, curiosities, &c., and your committee return the exhibitors their best thanks.

We regret that although ladies have been invited to join us, none have yet responded to our invitation. Other societies have their lady-members, and we all know that there is no lack of fair creatures whose dainty fingers are familiar with what has been termed "the black art" (in emulation of an example set by the highest lady in the land—our much loved Queen). Having good reason to believe this absence to be occasioned by the fear each individual lady, naturally enough, of always finding herself "the single lady" present, we are prepared to promise any lady who may honour us by communicating her intention of becoming a member and attending a meeting, that pains will be taken to introduce her upon such an occasion to companions of the same sex.

Your committee take this opportunity for throwing out the few hints following for the consideration of members.

It has been suggested that the formation of a permanent committee for the special purpose of testing and reporting upon the value of such improvements in processes, experiments, &c., as may be found in the various journals, would tend to point out their real value, so that they might be at once either adopted or discarded. A fund *(in the event of our increased prosperity)* might be placed at the disposal of such a committee for the incidental expenses; and at each meeting we should have a something certain to look forward to from our "experiment committee."

A complete collection of the literature of photography, periodical and otherwise, English and continental, to circulate among the members, is also a very desirable object of attainment, which our increased funds would enable us to secure.

A collection of first-class photographs might be added to the folio for the year, by the formation of a club, of which each member paid some trifling monthly subscription, and had, in turn, the privilege of naming the subject for purchase. The specimens so procured to be divided, and become the property of the members at the close of each year. Any members willing to aid in carrying out this suggestion will please to give in their names to the Secretary.

While the practical is made, as it deserves to be, a most prominent feature in our papers and discussions, your committee would suggest that theoretical and philosophical questions should by no means be neglected;—"purblind practice" will sometimes "every theoretic truth disdain, and blunder on mechanically vain," but, *as a society*, while we should not be characterised by a puffed out pride in the mere act of languidly hoarding up *embryo* knowledge, we should beware of separating elements of theory and practice which are so essential for the production of a perfect whole.

Your committee would also urge upon members the advisibility of making arrangements which will enable the Secretary to announce at one meeting the subject of the paper for the next. The representatives of this or that branch of special knowledge more directly pertaining to the subject to be discussed will then be more likely to attend, and thus improve and give increased effect to the discussions which it is so desirable should take place upon such occasions; for, it must be remembered, that photography has brought into harmonious relationship a number of apparently conflicting, or at least opposite elements, in *all* of which it is indeed seldom that we find any one or even two individuals tolerably proficient; and it might possibly happen that, from neglect of the method recommended and hitherto adopted, no gentleman was present at the reading of such paper competent to tender any observations, and thus the labour so generously undertaken in our favour might fail to meet an encouraging reception and adequate reward.

Your committee are also desirous of discouraging the habit of permitting discussion to degenerate into the low tone of ordinary conversation. If each speaker addresses, not only his more immediate neighbour, but *the whole of the meeting*, you will easily perceive that his personal views or opinions will have the better chance of being strengthened, improved, or refuted, which, as *the advancement of the art and not the individual* is the great purpose of our organisation, is of course especially desirable. Some may, from a fear of those awful beings—the reporters—hesitate to adopt our suggestion; but we can assure them that while the pith of all remarks worthy that honour will afterwards be found in print, the mere chaff of words which they themselves do not—indeed cannot—pause to separate from the wheat of sense, will, if only for the credit of the pages in which they appear, never be recorded against them These remarks of course do not apply to conversation unconnected with the subject under discussion. There are many other such hints as the preceding which might be urged upon your attention, but we will not detain you any longer with them upon this pleasant occasion.

To take a passing glance at the more prominent photographic features of the year will not demand many minutes. No great events, no very wonderful inventions, have characterised the past twelve months of our Society's existence. Steady progress in the practical departments, quiet advance towards the artistic, have been its most praiseworthy traits. Bottled light, which opened with a pop, and effervesced noisily all over Europe, seems again likely to be corked down. The alkaline gold toning bath has stolen into more general use and appreciation. The construction of lenses or their combinations have developed nothing novel, excepting a lens of an original character (Mr. Sutton's panoramic), which, together with its camera and other apparatus, was exhibited at one of our meetings, and which seems to offer great advantages in a largely increased angle of view, &c. Much, too, has been done in the way of reproduction during the year. We were delighted to find the educational authorities at Kensington had resolved to carry into the very humblest houses of the land we live in that refining and enobling influence which belongs to the real art, by making photography an instrument for the faithful reproduction of such costly works of the greatest painters as have hitherto been inaccessible and beyond the means of even the wealthiest among us. Many have, however, been looking vainly and impatiently forward to the delivery of these copies, and begin to fear that some members of the "Barnacle" family may have stepped in with their "how not to do it" system. When we consider that, aided by the camera, copies of these glorious productions can be scattered by thousands among the people, at a cost purely nominal, and that to produce one such without photography's aid would require the best talent of our greatest painters, at a cost of perhaps thousands, or at least hundreds, the importance of this step must, we are sure, be acknowledged with no little gratitude and pleasure.

Many productions of high artistic merit have been published during the year, which are especially gratifying as proofs that the almost latent pictorial power of our art, is beginning to be discovered and more generally appreciated. We may take praise to ourselves also, gentlemen, for having been one of the few, very few, societies which during the year have given due attention to the principles of art in connexion with photography, and denounced the more common and prominent offences against good taste and pictorial beauty.

One other subject, which we approach with some reluctance, remains to be noticed, viz., the collodion committee. It has indirectly done us good, perhaps; but it was certainly strange to find a body of highly talented gentlemen testing *collodions* with only *one collodion*, and solemnly and laboriously making a show of comparing *with nothing to compare with*, without referring to the invidious and ungrateful nature of their task in attempting to discover the best manufacturer instead of the best way of manufacturing. Their report reminds us of some one who (under government, of course) had nothing to do, and, with a great deal of help and plenty of time, contrived somehow to do it! But still let us thank the gentlemen forming the collodion committee for their good intentions, remembering that mistakes will occur, although it is not always policy to admit their existence.

In conclusion, we beg leave to suggest that the number in committee be increased from six to eight; that the hour of our usual monthly meeting be altered from eight to half-past seven; that as some of our members receive, in addition to that which has been chosen as the special organ of this Society, the journal pertaining to them as members of kindred associations, and do not require the two, the yearly subscription be reduced to those gentlemen, and others similarly situated, from 10s. 6d. to 5s. 6d., and that they receive for this sum the print and all other advantages of membership, excepting only the fortnightly Journal [The British Journal of Photography].

The privilege which has been granted to the members of the Walworth Literary and Scientific Institution will cease with the past year, as we have found the subscriptions paid less than the outlay incurred. In consequence of the present state of our funds, the privileges of members must cease until their subscriptions are paid in.

For the next three months your Society will only exist in the open air, "roving abroad like a bird or a bee," and like the latter, we hope, treasuring honey for the coming winter meetings. Our first out-door meeting will be held on the third Saturday in July, at half-past two P.M., at the Eagle, Snaresbrook.

The Treasurer will now read his report, after which we will, if you please, revive or recreate our newly defunct body of officers, which done, the President will gladly receive the names of any who may desire to be nominated as members.

Mr. Howard, the Treasurer, then read the financial statement, from which it appeared there were thirty-four subscribers to the Society, and that £24, 10s. 6d. had been received during the year. The balance in hand amounted to £1, 0s. 1d., which, with the subscriptions to be received, would fully discharge the quarter's expenses.

Members elected.—Messrs. Salked, Kay, Baily, Blanchard, Bunker, Neeld, Smith, Tate, Hooper, Young, Davies, Moulde, Squire, Evans, Brooks, and two other gentlemen whose names escaped us.

The following gentlemen were elected honorary members on the motion of Mr. Wall, as he (Mr. Wall) thought no photographic society should fail to do honour to itself by evincing its high respect for those who had done photography such great service in its scientific, practical, or artistic branches:—*T. F. Hardwich, Esq., O. G. Rejlander, Esq., M. Claudet, W. Crookes, Esq., R. Hunt, Esq., and Lake Price, Esq.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

The monthly meeting of this Society was held on Monday, the 18th ult., at the Golf Club-House, Blackheath Hill,—the President, Charles Heisch, F.C.S., in the chair.

The minutes of the last meeting having been read and confirmed,

Mr. Glaisher read a communication from Mr. Paul Pretsch, on

Photographic Pictures Reproduced by Ordinary Letterpress Surface Printing.

Mr. Paul Pretsch's new process, which is now brought before this meeting for the first time, is the earliest solution of the problem, whether we shall be enabled, by the aid of photography, to impress upon metal blocks for the purposes of printing by the ordinary letterpress, and with ordinary printing ink, illustrations of events and the truths of nature. The specimens produced have not in any way been touched by the graver. The inventor began with the most difficult portion of the process—the photographic originals. The great difficulty of the process will be readily understood from the fact, that there are no lines or markings in the originals, but only tints which must be reproduced on a certain solid substance from which the print is to be taken. It is interesting to know that, although the inventor is a German, the discovery was made in England. The main advantages presented by

* The Secretary thinks an apology due to these gentlemen for not privately intimating his intention of proposing them as honorary members; but the enthusiasm of the meeting did at once that which he merely intended to propose doing.

this process over the ordinary method of engraving are the rapidity and cheapness with which the impressed blocks may be produced. Where thousands of copies may be taken from ordinary engraved plates, hundreds of thousands may be printed from the blocks prepared by Mr. Pretsch. Whilst the price of an ordinary engraving ranges from a few shillings to several pounds, by the new process they may be produced for a few pence.

The superiority in favour of the new process over the old in point of time of production is as twenty or even fifty to one. The inventor states that these blocks are cheaper and more quickly produced than his former invention for producing engraved plates for the intaglio printing process. In preparing an intaglio printing plate, after the gutta percha mould is obtained, the inventor requires from three to five days for the electrotyping of the copper matrix, and for making the solid printing plate itself about ten days or a fortnight more were required; but in the production of the block for the letterpress printing only twenty-four hours are wanted after the mould is obtained. The copper deposit is made rapidly, being very thin; and it is then backed up with type metal and fixed in a block of wood, as in the specimen produced. The expense of electrotyping the blocks, compared with that of an intaglio plate, is about one to three or five, according to circumstances. The processes for intaglio and for surface printing have one and the same object. The influence of light is used for the production of the first printing plate or block; and having obtained this, the inventor becomes enabled to print therefrom with mathematical certainty, by mere mechanical means, any number of copies required. Photography alone cannot do this, for it requires the influence of light to produce each single copy; and even the various carbon and ink processes, although perhaps more durable than silver prints, require light for the production of copies. Both processes possess the advantage that their copies are printed with the ordinary printer's ink; and although the inventor is quite sure that his first process for producing engraved copperplates for intaglio printing will come into general use, and be applied to the cheap production of first-rate prints, still, considering that surface printing combines with the same fidelity of reproduction so many important advantages, we may presume that, without superseding intaglio printing, it will take its due place, and that the demand for these blocks will far surpass that for the intaglio plates. It thus appears that Mr. Pretsch has fulfilled his promise—that he would make photography subservient to the ordinary printing press.

Mr. Lucas said the new process would supply a great desideratum.

Mr. Glaisher said he had brought several prints and blocks, which he produced, prepared by the process. It would be observed that there was only a thin layer of copper on the block. The prints were wonderfully distinct and clear, and doubtless still clearer tints would be obtained by the inventor in time.

The President asked whether the process was the same as that employed in preparing the copperplates for intaglio printing, only stopping short of the final process? Had Mr. Glaisher any idea how the impression was made?

Mr. Glaisher said that, so far as he knew, a photograph was taken upon some impressible substance, and an acid was used by which some parts were raised and others depressed. From the mould so obtained he produced his copperplated block. The intaglio process had been patented, but at present the new process had not been. He believed the blocks could be produced as cheaply as ordinary wood blocks.

The President, Mr. Heisch, then introduced some photographs of fluorescent substances, kindly sent him by Dr. Gladstone, expressing his regret that he was obliged to leave the meeting, which prevented his personally describing them, but he would leave them in the hands of Mr. Wheeler for explanation.

Mr. Wheeler, Hon. Sec., took the chair, and stated that the committee appointed to secure a room for the contemplated *soirée* had sent in a report, from which it appeared that they had been unable to obtain the necessary accommodation.

The report having been adopted, it was agreed that the matter should stand adjourned *sine die*.

Mr. Wheeler stated that the offer made by this Society to present the Golf Club with a gold medal as a recognition of their kindness in allowing the meetings of the Society to be held in their rooms had been accepted with thanks.

A resolution was then moved by Mr. Harding, and seconded by Mr. Lucas, that Mr. Heisch be empowered to make the requisite inquiries, and take the necessary steps towards purchasing the medal.

Mr. Wheeler then proceeded to describe the experiments made by Dr. Gladstone relative to certain qualities of the solar spectrum with respect to photographs of fluorescent bodies. He claimed the indulgence of members for any shortcomings he might exhibit in dealing with the subject at so short a notice. He said, members were doubtless aware that, independently of the colours exhibited by the prismatic spectrum to ordinary vision, there existed to some extent throughout the spectrum, but at and beyond the violet end chiefly, invisible rays, termed extra spectral. Stokes had discovered that the bluish opalescent appearance manifested by a solution of quinine, when viewed in particular lights, and also the opalescent appearance of glass, coloured yellow by oxide of uranium, was due to the fact that these bodies had the property of reflecting and at the same time so altering the refrangibility of these rays as to bring them within the range of human vision: substances having this property have been named *fluorescent*. When viewed by ordinary lights, these bodies exhibit little or no peculiarity of appearance, owing to the number of ordinary luminous rays reflected equally from them and surrounding bodies; but, if illuminated by light that has passed through a violet-coloured glass, which contains few of the more luminous rays of the spectrum but the whole of the invisible rays, owing to their property of so altering the refrangibility of these rays as to render them visible, they appear in comparison with the ordinary bodies around them to be almost self luminous. Other lights, containing few of the more luminous and many of the invisible rays, may be used to exhibit these phenomena, and on that occasion he employed the light from sulphur burned in oxygen gas, when characters traced on writing paper with various substances, which by ordinary light were scarcely visible, became beautifully luminous. Other bodies possessed of the power, besides quinine salts and uranium glass, had been since discovered, those sent by Dr. Gladstone being disulphate of quinine, sulpho-stilbate of barytes, cumenate of potash, and esculine, the active principle of horse-chesnut, and chlorophyl. Mr. Wheeler then proceeded to remark that the chemical action of the spectrum was greatest at that part which contains most of these invisible rays. Without going so far as to assert that these rays are actually the *chemical rays*, it had occurred to Dr. Gladstone that the alteration of their refrangibility might also deprive them of their chemical action. Experiment proved the conjecture to be right, photographs of the fluorescent characters being undistinguishable from those of characters in ink. This was particularly evident in the photograph of some letters cut out in white paper, soaked in the fluorescent bodies, and pasted on a paper coloured blue by cobalt: in the photograph the letters appeared black on a white ground. These experiments are particularly interesting to the photographer, as establishing another link between the chemical and Stokes's rays. Mr. Wheeler concluded by stating that he was glad to have the opportunity of extending the subject he had partially unfolded to them at the last meeting of the Society, viz., the phenomena of light.

Mr. John Harding proposed a vote of thanks to Mr. Wheeler for his *impromptu* discourse, which was seconded and carried, and the meeting was adjourned until October.

LIVERPOOL PHOTOGRAPHIC CLUB.

The sixth meeting of the above Club was held at the residence of the Rev. Thos. Banner, on Tuesday, the 12th ult.

Miss Bahr, whose name has become deservedly famous for her admirable pictures by the Fothergill process, and of whom such honourable mention was made in connexion with the Exhibition of the Society of Fine Arts, presented several striking proofs from the above process. She attributed her uniform success to the extent to which the washing of the plates had been carried in their preparation. On taking them from the bath the washing was not limited to any stipulated quantity of water, as in every former case, for as much as two jugs of water had been lavishly poured upon each; and the solution of albumen, so weak as one part to seven of water, having been poured on, the same copious washing was again applied; they were then drained and dried with a moderate heat: the exposure had been generally six minutes, in a very bright light. Every specimen went far to sustain the position this lady has attained in the art, and were especially remarkable for sharpness of detail and minute definition. The contrivance of her camera admitted of the lateral shifting of the back, so as to bring every object, whether distant or near at hand, into accurate focus. A very artistic picture of *A Village Church near Conway*, represented the Little Ormeshead, not less than five miles distant, as distinctly as objects in the foreground.

Mr. Glover exhibited some very fine negatives from collodion with the resin, according to the mode prescribed by the Abbé Depratz. He had slightly departed from the original plan by dissolving one grain in two ounces of rather tough collodion, then soaking in a large quantity of water, frequently rocking the dish containing the plate.

The sensibility of these plates constituted their main charm, for in every other method of using preserved plates the exposure required is nearly as long as for waxed paper. In all these instances the exposure was nearly as brief as for moist or fresh plates—the stereoscopic size requiring only twenty seconds. They were sensitised in a rather acid bath, containing about five minims of glacial acetic acid to each ounce of the silver solution. The development was proportionately rapid; but the fluid was of the strength of three grains of pyrogallic acid to each ounce of water. This was managed under very peculiar circumstances: having elicited by a partial development, by means of a weaker solution, viz., one and a-half grains to the ounce, that every minute particular of the object had been fully though faintly brought out, the plate was cleared with cyanide, thoroughly washed, and when com-

pletely dried set aside. At leisure these plates were again moistened, and a further development carried on until the full force and depth required were entirely obtained. These specimens were singularly free from the usually objectionable hardness of dried plates, as they had much of the rich quality of recent or wet plates.

The Messrs. Cook brought forward some more of their very excellent waxed-paper negatives, which were taken, during a tour to Haddon Hall, under all the unfavourable condition of the weather of late. As there was very little sunshine many of them were exposed three quarters of an hour, yet were all of the very choicest description.

Mr. Corey complained severely of the great difficulty of obtaining albumenised paper of first quality. He had been kindly supplied by a house in this town who were celebrated for the excellence of the paper heretofore, but they, as well as himself, had been grievously disappointed with the pictures produced from it. Further application to other warehouses procured the like want of success: it was nowhere to be obtained in the town, and the photographers in Liverpool were left without a supply, unless they had recourse to London houses, and then the only reliable paper, viz., the Papier Rive, could scarcely ever be obtained with certainty.

The usual cordial interchange of experience and information was strikingly evident at this meeting, which separated at a late hour, after requesting Miss Bahr to honour them by becoming a member of the Club.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on the 13th ult., at the Chorlton Town Hall,—Mr. Wm. Griffiths, Vice-president, in the chair.

The Secretary read the report of the last meeting, which was confirmed. Afterwards he stated that some members had waited upon him relative to a report which appeared in the *Manchester Examiner and Times*, on the opening of the exhibition, Peel Park, which stated that the photographs there exhibited were the production of members of the Manchester Photographic Society; and as some of the members of this society had contributed pictures, they wished the report should be corrected. Agreeing with that wish, he had written to the curator of the Peel Park Museum, and had received a reply, which stated that it was quite immaterial to the committee who were the artists, and requested the Secretary to write to the editor of the *Examiner*. That paper has since published your Secretary's letter, which states that the Chorlton Society has contributed to that exhibition.

The meeting approved of the Secretary's conduct in this matter.

Mr. John Fawcett said he had brought a small quantity of composition that he used for producing the artificial light mentioned at the last meeting. He did not think it would be very interesting at this season of the year. It was difficult to experiment with this composition, as he did not like to use a lanthorn, being afraid of some imaginary patentee running foul of him; and when he used it in the way he should describe, there was quite a commotion near his house in consequence of the great light. He had intended to take a picture to show to this meeting, and had arranged with a good sitter for the purpose. He had arranged for three fires outside his gallery, ready for lighting in their proper positions. His wife was ready to assist in the lighting, the sitter was arranged, and all preparations completed to expose. The fuses were then lighted, and the exposure commenced, when immediately a person in bed in a room across the street, alarmed at the light, jumps out of bed, dashes his head through a pane of glass, raised an alarm which caused a commotion in the street, and disturbed the sitter, although he was a practised one! All this occurred in less time than it has taken to describe it. Of course he was unsuccessful, and regretted that the specimen could not be shown to the Society. The exposure required was about four seconds. Before the close of the meeting he would light the composition, and if any gentleman desired it he would give him the formula; or if any gentleman wished to try the experiment, he would be glad to supply him with a small quantity sufficient for the purpose.

A discussion followed on the advantages of the oxy-hydrogen lime light in comparison to this, which was raised by Mr. Hooper; but Mr. Fawcett assured the meeting that he would only think of using this light for pictures direct, as the expense of copying by this light would debar its use, and the light from the oxy-hydrogen light was insufficient for direct pictures.

The Secretary was requested to prepare a list of the members, to be filled up by them, to show the processes that each member was acquainted with for reference at the future meetings.

It was proposed and carried that an extraordinary meeting of the Society be held at the Peel Park Museum, to discuss the merits of the exhibition, on the following Saturday. Several members assembled on that day, and after spending some time in examining the pictures, retired to tea. They afterwards agreed that the following pictures were worthy of special notice, Mr. Mudd's prize picture and the productions of members not being included in the criticism:—*Cæsar's Tower*, Mr. H. Thorpe; *Slate Quarry*, Mr. J. L. Davies; *At Bettwys y Coed*, Mr. W. T. Mabley; *South Stack*, Mr. G. Higgins; *Bridge over the Lune*, Mr. H. Thorpe; *Whitby Abbey, Interior*, Mr. Crompton; *Carnarvon Castle*, Mr. E. Mann; *Tubular Bridge, Conway*, ditto; *On the Irwell*, Mr. Alfred F. Smith; *Ambleside*, Mr. G. Wardley; *Bettwys y Coed*, ditto; and *The Hostelrie*, Mr. J. L. Davis.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

You have now to continue your work until you have obtained the requisite degree of finish, roundness, and force of effect.

Although I have described the painting of the head first, you should have got in progress other portions of the picture, as, when all parts advance simultaneously, there is less chance of mistakes in the *chiaroscuro*, relief, or arrangement of colours. The background may be washed in with any of the following colours or mixtures: —

FOR A GREENISH BACKGROUND.

Burnt sienna and Prussian blue.
Blue, burnt umber, and raw sienna.
Yellow ochre and indigo.
Sepia, gamboge, and indigo.
Indigo and gamboge, with or without a little burnt sienna (as the *photographic* background may decide).
Yellow ochre and lampblack.
Lampblack and gamboge, &c.
Raw sienna and cobalt.
Bistre and Prussian blue.

FOR A SKY BACKGROUND.

Indigo and cobalt.
Cobalt and madder pink or French blue.
Prussian blue and madder lake.
Cobalt, madder pink, and Chinese white (used thin).

FOR CLOUDS, HORIZON, ETC.

Yellow ochre, rose madder, and cobalt.
Sepia, rose madder, and cobalt.
Lampblack and indigo.
Black lead.
Sepia and cobalt.
Lampblack and lake.
Payne's grey.
Vandyke brown and indigo.
Vandyke brown and raw sienna.
Raw sienna.
Raw sienna and brown madder.
Yellow ochre alone, and with brown madder.

FOR WARMER BACKGROUNDS.

Raw sienna and Vandyke brown.
Sepia and brown madder.
Purple madder.
Burnt sienna and sepia.
Raw sienna, brown madder, and indigo.
Light red and sepia.
Brown madder and indigo.
Indian yellow, burnt sienna, and indigo.
Lampblack and lake.
Sepia and purple madder.
Vandyke brown.

FOR A COOLER BACKGROUND.

Lampblack and French blue.
Lake, indigo, and Indian yellow.
Payne's grey and burnt sienna.
French blue, brown madder, and burnt sienna.
Vandyke brown, lake, and indigo.

I have given you these mixtures, but their proportions and selection must of course rest with yourself; and you must be guided by the effect you wish to produce in making the last or mixing the first, remembering that your picture's artistic value is dependent, to a great extent, upon a judiciously-managed background. (See maxims).

Say, you are working a greenish background—well, you have to avoid making it of too uniform a colour, too cold or too flat (from the want of light and shade); and having laid on your wash, and evened it up, if necessary, with a hatch or stipple, or both, continue to work upon it until, without appearing to be perfectly unconnected with the figure, it throws the portrait well before it by its quiet and retiring character. That it may look as little like paint as possible (see maxim 52) hatch different colours over the whole, making it warmer or cooler here and there, as the colour of your drapery or nature of the subject may suggest. (See maxim 53). A dark background produces the most forcible effect, but it should not be so dark as to kill the deeper shadows of the flesh.

Or, supposing you desire a sky background, begin with your wash, and hatch or stipple it into various gradations of light and dark, warm and cold, working in clouds, if desirable, by leaving the space for them untouched by the first wash, and then touching them in with the colours given for the purpose. These clouds frequently enable us to extend the light or dark; to vary the colours, or repeat "bits of colour" which might otherwise appear patchy. The first wash should always be more pure and bright than it is intended to remain. Every mixture of colour for the washes should be made with due reference to the cold or warmth, and the light or dark character of the photographic ground you are about to cover. For a sky background it should be light.

When the background is so good in the photograph that it is merely desirous to change its tone, a clean, clear, simple wash will answer. There is a pigment prepared from red chalk which washes with singular smoothness and flatness, but which is not kept by all colour makers.

Opaque backgrounds may be secured with washes of body colour, which are usually thus applied. The tint is mixed with as little water as possible, in order that the colour may not be too fluid; and the mixture must rather be too dark than too light. The background is slightly damped, and the tint applied as a wash. You must be very careful not to go twice over the same spot till it is quite dry. A very good colour is made with ochre, lampblack, and Chinese white. I do not admire, however, nor recommend opaque backgrounds. Such grounds may be also obtained by rubbing in powdered crayon with the finger. If your subject be pale, that pallor may be prevented from appearing unpleasantly ghastly by causing your background, with contrast of colour, to give it warmth. If too red, by the introduction of some accessory of a brighter and more powerful red you may make it appear less strikingly so. If too brown, you may improve its aspect by introducing stronger and more decided browns in the background, and so on, without at all violating the truth of nature.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

J. S.—The colours you have, but do not recognise under their ancient cognomen, are however the same as we now use. The French colours may be very easily re-christened with English names. The "Precipité d'Or Rouge" may be imitated with carmine and black. You have put too much white in your colour. Perhaps the magnifying lens may be useful, but it should not be taken up until you perceive with the naked eye nothing more to be done.

North London.—Yours is the best picture any pupil of mine has yet sent me to criticise. Persevere, and your present master is likely to become your pupil, for he will never be "too old to learn," he hopes, till he is too old to live. More roundness is wanted. The background is too coldly and purely green. By deepening the cast shadows you would perceive at once that there was a general want of force and effect. The jewellery is ineffective from a want of shadow and too many high lights.

Foreign Correspondence.

Paris, June 25, 1860.

I will begin my letter by replying to the question about Disderi's card-portraits, which your correspondent, "T. R. A.," addressed to me indirectly in the last number of The British Journal of Photography. I have long known Disderi. On his arrival at Paris, some six years ago, he brought me his first attempts, and I immediately predicted the success which he at present enjoys. I have often seen him operate; but, wishing to reply with more exactness, and to ascertain whether any changes had been made in his method, I went to his rooms yesterday. I found the crowd in them as numerous as it always is, and it was not without difficulty that I gained access to his operating-room. In my presence he took four portraits in the space of twenty minutes, giving to each model two different attitudes. The objective that he makes use of is a four-inch Voigtlander. He places it at about eight metres from his model. Each glass moves in a grooved frame, and serves him for eight clichés. The exposure yesterday—at five o'clock in the afternoon, and with cloudy weather—lasted from ten to twelve seconds. Disderi develops with protosulphate of iron, and, to give more vigour to the picture, he pours over it a small quantity of three per cent. solution of nitrate of silver. He fixes with hyposulphite of soda. Such is, in substance, the process employed by this talented operator. Of course, the artistic skill with which he places his model in good attitude and in good light, counts for much in the beauty of the results obtained; but that skill is to be taught by good taste and experience, rather than by rule.

Several of our principal portraitists, and, amongst them, Pierre Petit (the rival of Disderi for visiting-cards), and Mayer, Brothers, and Pierson, employ for this kind of portrait a new apparatus, which they find very convenient. It is a dark chamber, opening and shutting in accordion fashion, or like a telescope, and divided in the interior into four compartments, with four objectives, each of which represents, within a few millimètres, the dimensions of the card. Instead of the ground-glass, there is a multiplying frame opening into two parts, and allowing the glass, which is contained in it, to receive the impression of the light by the four objectives at the same time, and upon one-half only of its surface. The frame being slid on in its groove, the second half of the glass receives its impression in the same manner, so that the operator can give the model two sittings in one. Thus, in two exposures, eight portraits can be obtained on the same glass. The economy of time resulting from this system will be at once understood—an economy of time not only in the obtaining of negatives, but also, and especially, in the printing of positives. The apparatus is due to M. Hermagis.

I trust that, whenever the occasion offers itself, your readers will put such questions as the foregoing: it will be a real pleasure to me to answer them. On my side, I shall frequently have to ask for information on behalf of our French photographers. I think that such interchange of practical knowledge between the artists of the two countries will be profitable to all, and that it is the duty of the press to encourage it.

The meeting of the French Photographic Society, at which I was present, responded but imperfectly to the promises held forth in the programme. Experiments were made by M. Wulff similar to those made last year by Mr. Moule before the Photographic Society of London, if I remember rightly. The illuminating powder employed was the same in both instances. It gave a steady and very intense flame, but unfortunately produced thick vapours. In the ante-chamber was arranged the apparatus, consisting of a large lantern, provided in front with a blue glass reflector to diffuse the light, and in which a rapid current of air was established by means of a tube communicating with one of the chimneys. A collodion glass was put into the camera placed below the lantern, and the powder was then lighted. The exposure lasted about seventeen seconds, one of the persons present acting as model. The result of the first attempt was null, and, on the second trial, a very feeble positive picture was obtained. It is much to be desired that the system should be perfected; for, although it is obviously useless to operate with artificial light whenever we can employ the light of day, yet there are circumstances in which such means might render great services, as in the case of monuments below the ground, and of the curious grottoes found in certain mountains, the marvellous aspect of which could not otherwise be reproduced; and also for interiors that are insufficiently lighted.

M. Bertsch presented a very fine picture of about eighty by sixty centimètres, obtained from a stereoscopic view of M. Ferrier's, by means of his amplifying apparatus. This apparatus differs from Woodward's solar camera in the following manner:—the rays brought into one pencil by the magnifying-glass are then rendered parallel by a concave lens which transmits them upon the whole surface of the cliché.

M. Girard submitted to the meeting a picture obtained on a sheet of paper waxed and sensitised, which had been enclosed for a whole year in M. Marion's preserving apparatus. The image was not so perfect as it would have been, if operated on immediately after the preparation; but as it is not necessary to wait a whole year, even when we are travelling, the result is very satisfactory. Much interest was also excited by several specimens of M. Paul Pretsch's typographic printing process which the inventor had sent to the Society.

I think I have given you about the whole of the proceedings of the meeting. I pass over the private conversations and the claims of priority which do not concern me, and I add, in conclusion, that two able photographers, MM. Bisson and Tournachon (the brother of Nadar), are installed, with arms and baggage, at the *Concours Agricole*, open at the present moment in the Palace of Industry, in the Champs Elysées. The administration has entrusted to them the photographing of the prize animals at this *concours*, and has divided the labour between them. Their tents are erected in the Exposition itself, and the police guard the entrance against the too curious crowd. Thither are led the lusty oxen and gentle heifers, the mettlesome horses and phenomenal sheep, and last, though scarcely least, the prize pigs, grown powerless from force of fat. It requires a rapid manipulator to seize the favourable

moment for photographing these moving models not unfrequently startled at the sight of the objective pointed at them, the difficulty would be greatly diminished if the sun would but shine out, but he persists in hiding himself behind a thick veil of rainy clouds. However, I have seen these artists operate and succeed in spite of the obstacles to be surmounted. I will add that one of them, M. Tournachon, successfully discharged similar duties in 1856. His collection of types of breeding animals, engraved in part by M. Riffaut with M. Nièpce de Saint Victor's heliographic engraving process, is one of the most remarkable works which photography has hitherto produced. ERNEST LACAN.

Photographic Apparatus, Processes, &c., &c.
Murray & Heath, Piccadilly, London.

This is *not* a catalogue, as its designation might lead one to expect; and though published by a well-known firm connected with the commercial phase of photography, and for the legitimate object of placing prominently before the public the articles in which its members deal, it contains some useful information to photographers generally, even to those well skilled in the art, and is well worth procuring. We find here and there extracts from this Journal, but with our oldest title of *The Liverpool Photographic Journal* affixed thereto. Is it possible that the compiler was ignorant of the change of designation adopted of late? If he thought our opinion worth quoting he might have given us our proper title. Little Bob expects to be called Robert when he grows to manhood. In addition to useful reprints, there is a fair share of valuable original matter contained in this pamphlet, in proof of which we give the following extract relative to Mr. Macnair's mode of preserving dry collodionised plates by the aid of an infusion of malt—a method that has been found very efficacious in the hands of those well able to judge of its merits:—

MR. MACNAIR'S MALT PRESERVATIVE PROCESS.

"We are enabled, by the courtesy of Mr. Macnair, who writes to us as late as yesterday, to mention here the experiences of himself and friends, among whom are some of the best amateur photographers in Scotland; It has resulted from experiments that the infusion of malt as described in the journals is needlessly strong. Mr. Macnair writes—'*Three* or *four* ounces of malt (instead of seven) to twenty ounces of water will be quite strong enough, and it has also the advantage of being easily washed off.' For larger or smaller quantities, of course the malt and water will be used in like proportions to the above. Mr. Macnair adds—'An objection to this process has been made, because the infusion of malt does not keep longer than a few days, but I do not think that is of any consequence, as it can be made at any time in small quantities, about as easily as a cup of coffee.' The easiest way to make the infusion, is to pour the water when nearly boiling into a common earthenware tea-pot, and mix in the ground malt when the heat has fallen to 180°; then place the tea-pot before a moderate fire, from which it should be removed, and the infusion allowed to cool slowly, as soon as it has acquired a *slightly sweetish* taste; if allowed to become *too sweet*, it does not dry hard and firm on the collodion film, but keeps sticky, and applying heat makes it more moist.

"The plates, which should be particularly well cleaned, and care taken to avoid dust, are to be coated and sensitised in the ordinary way, and the free nitrate of silver washed off at a tap, or with a jug, finishing with distilled water. The free nitrate will have been got rid of, when the greasy appearance which the plate has when the water is first applied is entirely removed; the plate will then be sufficiently washed. Rest the plate for a few seconds on blotting paper, and before it begins to dry, pour over the malt infusion the same way as collodion; wipe the back of the plate, and then dry (the quicker the better); this may be done by placing the plates in a box before a fire, ranging them in a slanting position, with the end from which the collodion and preservative coating were poured uppermost, and the coated side inwards. A large earthenware bottle, filled with hot water, placed in the box will greatly accelerate the drying, it is a good precaution, particularly for beginners, to touch the edges of the plate with varnish, applied with a small camel hair brush, after the coating is quite hard and dry; this lessens the risk of the collodion film breaking away while the preservative is being washed off.

"The time of exposure for taking views may be reckoned the same as wet collodion.

"After exposure, wash off very thoroughly the preservative coating, letting the water flow from the centre of the plate towards the edges; then, using a plate-holder, dip the *face* of the plate in a solution of nitrate of silver, of the strength of ten to fifteen grains to the ounce of water. Develop with the strong solution of sulphate of iron, as given in the last formula in our article on developers, and intensify, if necessary, by the solution of pyrogallic and citric in the manner previously described for this purpose.

"The science of malt as a preservative Mr. Macnair some time since thus explained:—'In the course of some interesting remarks on the changes grain underwent in the process of malting, he stated that the malt in a dry state contained gluten, gum, starch, and a sugary matter which did not crystallise, and which he believed could not be crystallised without sulphuric acid, or by some other chemical process; that when an infusion of ground malt was made at a proper temperature, a rapid conversion of the starch, as well as nearly all the gluten and gum, took place, and the whole was changed into a new sweet matter; that the conversion could be checked at any stage, and that the best state for the purpose was when the infusion, when dried upon the plate, was *least deliquescent*, and contained only sufficient quantity of this grape sugar to allow it to be readily washed off the plate after exposure.'"

A Complete Set of Adhesive Photographic Labels, of nearly 100 *varieties.*
Horne and Thornthwaite, Newgate Street, London.

This is a little book that we feel very much inclined to "cut up," and the chances are decidedly in favour of our gratifying such inclination. It cannot be regarded as light reading, and the character of the type is unusually monotonous, though sufficiently marked and legible. Lest our readers should be under the impression that we are just now in a particularly savage humour, we may remark that this "book" is intended for being "cut up," not figuratively but literally, and consists solely of useful labels, ready for being affixed to the various bottles belonging to the photographic laboratory.

Curiosities of Science. Second Series. By John Timbs, F.S.A.
(Kent & Co., Paternoster Row.)

We remember that, in the early days of our connexion with the Art of Photography, when journals devoted to the subject were still in the womb of the future, we used to make a point of securing Mr. Timbs's New Book of Facts, as in it we were sure of finding all the new facts relating to the infant science that had been made public, no matter where, during the preceding twelve months, Mr. Timbs being an indefatigable collector. We cannot, however, undertake to criticise in these pages any work not having a direct bearing upon photography; and therefore can only say, that though we find many amusing anecdotes relating to science generally, the work before us does not properly fall within our scope. We find, however, the following in relation to an agent much employed by photographers—chlorine:—

"Discovery of Chlorine.—At the close of the last century, the Swedish chemist Scheele made a series of experiments on the black oxide of manganese. To some this might have seemed an unprofitable waste of time; but what was the result? Chlorine was discovered, a substance of the greatest importance in the arts. Berthollet finding that this gas changed the colour of the corks of the bottles in which it was confined, suggested its employment as a bleaching agent. This led to a total revolution in the art of bleaching, shortening the process from several months to a few hours."

TO OUR READERS.

To meet the additional expense incurred for carriage and postage of this Journal throughout the Provinces, arising from the great bulk it has now assumed through the increased amount of matter published in each number, our Provincial Agents will be compelled to charge this and all future numbers at 4d. each. The price to purchasers in London and Liverpool will remain the same as at present, namely, 3d.; and subscribers can still have it forwarded direct from the publisher as heretofore upon payment of 8s. per annum IN ADVANCE.

Correspondence.

☞ We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.

PHOTOGRAPHIC GOSSIP.

No. III.

To the Editor.

Sir,—Referring to your leader of 1st proximo, I do not subscribe to the remark that I had thrown a stone at the practice of printing a proof from several negatives, combining portions of each. On the contrary, the last words of my letter were—"I certainly advocate printing from several negatives, but let them be legitimately obtained." So far, then, we can scarcely be said to differ; but, in endorsing Mr. Robinson's principles, you advocate that which I contend to be injurious to photographic art. A small stream of water from a print-washing machine is a sorry apology for a flowing river, with its beautiful reflections and sweeping eddies. The addition of a handful or two of stones and gravel makes it a very untruthful substitute for the bed of a rocky river, with its water-worn boulders. The deception is, as you say, an "admitted" one; but it is not, as you also say, an "agreeable" one. Fenton and others you name do not adopt such a method. In the composition, *Don Quixote*, Lake Price does not take a boy, and, borrowing a beard at his barber's, by some dodge or other distort him into a man. He is too truly an artist for that. Rejlander, in most of his unsurpassed compositions, follows truth closely enough; but when he departs therefrom he pays the penalty—as, for instance, the total loss of all effects of atmosphere and distance, so that a woman supposed to be watching, through a window, her husband toiling up a hill, really conveys the idea that she is looking at a picture stuck on the wall a few feet off. Enlarging a correct model is *not* departing from truth, and, therefore, if Rejlander cannot procure a column or archway, &c., large enough for his purpose, he is perfectly justified in bringing his camera near, so as to enlarge a small one, but he must not attempt to get distant (?) scenes in his back yard. I am quite ready to admit that Mr. Robinson's deceptions are very clever, but would greatly prefer seeing his talent directed to the production of such compositions as his first, *Fading Away*, a work of which any photographer might well be proud.

I cordially coincide with most of the sentiments in Mr. Wall's article in your last number, but I would allow the photographer the same license as an artist claims. He may even employ "dodges" to a liberal extent, and although I cannot say exactly *where* the line should be drawn, it would certainly be a long way short of throwing up a heap of rubbish in a back yard and calling it the top of a mountain!

I am, yours, &c., MICHAEL HANNAFORD.

[In replying to Mr. Wall's objections, we have already answered most of those made above; the remainder our correspondent himself refutes. It is (according to his own doctrine) allowable to *enlarge* a model. What proof has he that the "model of a mountain" was a "mere heap of rubbish," and not truly a *model* of the *top* of a mountain? Again, in *Nearing Home*, the "distance" exhibits a considerable degree of atmospheric effect. We are a little puzzled to understand how our

correspondent can "cordially coincide" with Mr. Wall's recent article which is specially directed *against* the use of several negatives for one composition, while he himself professes to "advocate" the practice. We have no doubt of Mr. Robinson's negatives having been "*legitimately* obtained," and do not for one moment suppose that our correspondent would suspect him of having *stolen* them.—Ed.]

FADED POSITIVES ON GLASS, CARBON PRINTS, &c.

To the Editor.

Sir,—Having devoted much of my attention to the photographic art in all its varied branches for several years past, I may very naturally be expected to have stumbled on, at least, many of its discouraging interruptions. By carefully retracing my steps, I have generally been enabled to set matters right again; but in the case I am about to trouble you with I have thus far failed of my usual good luck. In the hope that the superior knowledge of yourself, or of some one of your numerous correspondents, may more readily see through my difficulty (perhaps from having been similarly circumstanced), I am induced to bring before your notice the following mishap:—

1. Working for two years past entirely in the positive glass process, I have always found the high lights of the picture to have preserved their purity most perfectly, and without the slightest change of colour. Lately, much to my disappointment, I have been shown two proofs (and there may be others scattered about the neighbourhood) which have taken on a deep saffron-yellow colour, the discolouration being confined principally to that part of the picture exposed to light—that part covered by the matt being very much less changed in appearance. Three other proofs taken at the same time as one of these, of the same person, and with the same chemicals, and, I believe, protected by the same varnish, still remain unaltered. Anxiously hoping to be obliged with an explanation of the cause of the above annoyance in an early issue of your most useful periodical, I will trouble you no further on that subject.

2. Very recently I have found that the flooding of the glass positives, with one part of albumen to three or four of distilled water, has produced a better surface for receiving powder colours than that of the bare deposit of silver. Is it possible that the phosphorus or sulphur contained in the albumen may be the cause of a decomposition taking place, and consequent discolouration of the picture? I recollect reading somewhere very lately, in a photographic periodical, of paper proofs having quickly faded in consequence of having been varnished with albumen. I should have stated that, at the time of taking the pictures which took on the above described undesirable change, I had not commenced using the coating of albumen.

3. The print kindly presented by M. Joubert to the subscribers of the *Journal of the Photographic Society* with its last number is certainly very beautiful. It is full of half-tone, of a rich sepia brown, with its high lights perfectly clean and white, and free from that coarseness or roughness of surface usual to all former carbon prints. In short, to my mind, as far as its present appearance goes, it is perfect, and quite equal to a silver printed proof. Of course photographers (and the public too) must wait patiently, in the hopes of eventually being favoured by M. Joubert with the generous publication of his process, as led to expect it is his intention of doing. In the meantime, I think M. Joubert would be conferring an additional favour, more especially on the amateurs of our fascinating art, if he would inform them whether the proof in question was printed by means of light in the ordinary way of taking a silver proof, direct in the pressure-frame; or whether the negative used was first prepared by some galvanic process, and the proof taken in the printer's machine used for printing engravings. The last method would necessarily be only applicable where a number of copies were wanted, the first being more especially suitable to the requirements of the amateur—and a boon indeed it would be to photographers generally.

One query more and I have done. Can you kindly oblige me with a detailed method of making artificial ivory, as used for taking positive pictures on? or, what would be still preferable, where the article could be obtained ready prepared in sheets, and fit for immediate use?—I am, yours, &c., HENRY H. HELE.

June 18, 1860.

[1. Is it not possible that in the case of the positive which changed colour, where the albumen was not used, your fixing agent (cyanide or hyposulphite) may have been nearly saturated, and thus have left behind a very small portion of iodide or bromide of silver, which did the mischief? This would account for the same chemicals not failing in previous instances.—2. We should think albumen a dangerous varnish for positives. It is, however, not improbable that if properly coagulated it might be harmless. To this end, immersing it in a solution of protosulphate of iron after drying, and washing thoroughly, may be effective.—3. M. Joubert's carbon print is by far the best we have seen of that kind of work. Our own copy happens to be a poor one—dull and flat: we have seen those which are much superior produced by this gentleman; but still, in our opinion, a long way behind a good silver print. It has already been stated by M. Joubert that each proof is produced *in the pressure-frame* by *exposure to light*.—4. Artificial ivory is composed of albumen and sulphate of barytes, but how combined we do not know. It was introduced by Mr. Mayall, of Regent Street, by whom, we believe, a patent was taken out for its manufacture.—Ed.]

CAUTION TO OPERATORS ANSWERING ADVERTISEMENTS.

To the Editor.

Sir,—It is high time some caution were given, through the medium of photographic publications, respecting the advertisements of parties requiring first-class operators, either for the field or gallery.

In illustration of my meaning, I will mention *one* of *two cases* as having occurred to me. Six weeks ago I answered an advertisement of this kind which appeared in one of the photographic publications; and after forwarding specimens and reference, both of which proved satisfactory, I was engaged, and came a distance of 300 miles. In the short space of *two weeks* I was treated to a great surprise, that of *one week's notice* to leave, the excuse being—the truth of which I do not for one moment doubt—that owing to a disappointment in some money matters my employer would not be enabled to continue my services any longer, although he admitted my capabilities as a first-class operator. I, of course, left, at the same time knowing there was a remedy against such treatment; but, upon consideration, I found no advantage would accrue were I to apply to a court of justice where the offender was not worth "powder and shot."

Unless professional photographers have the means at their disposal to battle against the many ebbs and flows to which the photographic business is prone during the year, they ought not to mislead operators by startling advertisements. I am thoroughly convinced that many of them are only put forth as a trap to catch some first-class operator, and, after well picking his brains, in a few weeks discharging him with sundry excuses tantamount to nothing.

I think it would be a boon to photographers if some respectable firm, such as Messrs. Knight and Sons, Horne and Thornethwaite, &c., were to keep a register of parties *wanted* and wanting situations—in both cases a reasonable sum to be charged per month; and in the case of operators requiring a situation, to leave at the register office a specimen or specimens of their *own* guaranteed productions. Where the specimens shown were not first-class a refusal might be made to place the party on the register.

Trusting, as a lover of justice, you will insert this,—I am, yours, &c.,
JUSTITIA.

PREPARATION OF NITRATE OF SILVER, &c.

To the Editor.

Sir,—Wishing to prepare my own nitrate of silver, I dissolved a coin in nitric acid by means of heat. I continued the application of heat until the whole of the liquid had evaporated, leaving a *green* crust, which, having broken up, I proceeded to wash, but, contrary to my expectations, the crystals after being redissolved still retained the same *green* colour. 1. Will you be kind enough to point out where the fault lies, and how I am to go to work to ensure success? 2. At the same time will you oblige me with directions for preparing chloride of gold? 3. Is there a book on the preparation of chemicals more explicit than Hardwich's?—I am, yours, &c., LUNA.

[1. The green colour is due to the presence of nitrate of copper, which may be got rid of by raising the heat very considerably, so as to fuse the product; the nitrate of copper is thus decomposed into black oxide of copper, insoluble in water, and oxides of nitrogen, which escape. If you wish to prepare nitrate of silver you will save yourself much trouble by purchasing pure silver, sold at about five shillings and sixpence or from that to six shillings per ounce.

2. To prepare chloride of gold we advise you to apply to a refiner of the noble metals, such for instance as Messrs. Johnson and Matthey, of Hatton Garden, E.C., and obtain pure gold in the form of a brown spongy mass. Dissolve thirty grains of this powder in a drachm of nitric acid, mixed with four drachms of hydrochloric acid and four drachms of water, evaporating to dryness at a gentle heat.

3. We are not aware of the existence of any *better* work. Mr. J. B. Hockin also gives some information upon the same subject.—Ed.]

HONESTY *v.* PHOTOGRAPHY.

To the Editor.

Sir,—The title of my letter may seem strange to some eyes. I wish there were no occasion for it; but cases are daily occurring which seem to call for some animadversion. The *Journal of the Photographic Society* furnishes us with one instance in its last number, where it is stated that some unprincipled photographer has desired to be furnished with Crystal Palace season tickets for members of his family, on his sending (as his own), for exhibition, works by other artists which he had purchased. Conduct such as this seems to demand our severest reprobation. Photographers have been zealous of late in denouncing what they call trickery, or contrivances by which certain effects may be produced. This is a large subject, and much has been written about it in reference to painting; but these mechanical dodges are quite put into the shade by those which offend against morality, and remind one of the trite proverb, so applicable to photographers, about inhabitants of glass houses. A case before your Liverpool magistrates a few months ago is quite in point: an assistant had made use of negatives belonging to his employer. There was also an advertisement of apology in the *Athenæum* of the 9th instant, from which it appeared a copy of a published portrait had been

taken without leave. Now, what would be said if an amateur made use of private opportunities to re-hang, for his own satisfaction, pictures sent for exhibition, particularly if those pictures are not strictly his own; and this leads me to ask if plates prepared by a friend, and perhaps developed by him, can, with propriety, be called the productions of a person whose only share in them has been the exposure. If I buy prepared plates (Dr. Hill Norris's, for instance), and treat them myself, am I not bound, in honour, to state the fact of their being so purchased? These remarks would be unjustifiable if instances did not occur; and, though it is not allowed publicly to give names, and say of such an one "thou art the man," yet they may go home, I hope, to some who ought to know better; and the sooner photographers purge themselves from such proceedings the better: their art is no exception to the rule, "Honesty is the best policy."—I am, yours, &c.

Manchester, June 25, 1860. DETECTIVE.

MRS. SPRIGGINS NATURALLY INDIGNANT.

"He as steels my pus steels cash but he as steels my name steels wot his godfathers and godmothers didnt promise for him."

To the EDITOR.

SIR,—Its meen thats wot it is, but I'in better than I wos thanks be· I never thort I should a got over the atack a spazzums I ad wen I looked in the fust of June number of the *British Journal* and sor as sumdy ad been a pursonation of my name. I went off and never new weather I wos on my ed or on my eels till I found myself in the twopairback's arms a givin me stuff out of a black botle as he keeps along with his tea and shuger with a large PIZUN writ on it for the children would touch it. Well it tasted just like gin the nasty stuff wich I never could a bare and it did me a grate deal a good. The weigh of it wos this. You must no the twopairback lends me the *British* reglar now since I'm a contribulatur and wen he giv me the fust of June "Woman" sez he "thy name is disseet" "Sir" sez I nettlin up "my name aint wot you sez but Spriggins and your know man to call a unpertected female a woman." "Mrs. Spriggins" sez he "you've diseaved me it wos only last Thirsday as you wos appraisin of Mr Robbingsons picturs down the street up to the skize and now I sees this letter" a shakin the fust June number in my phace which I sez "Explane yerself if your a gentleman" "Read that" sez he which I did and faints a way like a stone imediate. Howsever I cum two wen he giv me the pizun but it wosnt till he giv me sum more in ot water with sum shuger to act as a nantydoke he said that I cum two kwite and was able to read the trash agin. I never felt so overcum since that voil uzzy of a nus as I ad with my secund bein weekly and couldnt nus her meself wore my blue satting bonnet with the yaller fether on the pier and all the town said "Lor there goes Mrs Spriggins out and the baby only five days old tho it is summer whether which Sir is nether ear nor there no nor anyware else ether along if this orrid rane and aint likely to be leastwise this year and took her for me. Phansy the phelins of a reseptable female at bein called a suspicious carakter in print and he's no gentleman and I dont care who nose it. I scawn revenge or I'd carry it afore a British Jedge and Jewry and then see who'd look suspicious. Suspicious indeed! (Here Mrs. S. enters into particulars concerning the respectability of her family—paying her way, the various offers of marriage she has received during her widowhood, the Volunteers and the bad weather, which are very interesting, but wholly irrelevant to the matter in hand).

And then his preshus perduction is one mask of lise and bad gramer. The twopairbax name isnt Snooks I should jest like to see a lodger of mine with sich a vulgar name, the retch I'd charge him dubble rent and his brother will never put his knows under my rofe as long as there's nales on my ands after the frite he made of me wen I had my likeness took I should like to see him the meen villing. And if the patchwork kwilt was made by my Grandmother why should he turn it into reticule. As to lecturin at the Photographic Society I dont a proov of ladies lecturin anywears out of there domestic spear and the twopairback sez I'm write for he nose won Photographic Society as is kwite spiled with a parsel of old wimen a lecturin and afussin about it. My boy nose better than smokin and guzzling grog in my place. Let me kitch him at it thats all. Then wot he say about certing females as I would not defile my pen to name its simply ridiclous let alone undecent. I have red your remarx about Mr. Robbingson's pictures and beautiful they are perticly the young gal a dyin and the pore thing's mother a cryin and the dear old father a lookin out a winder so that they shant see him a cryin. I nose he's a cryin tho I can't see his phace. They have got it down the street and I alwys stops and as a good cry for you nose a mothers pheelinks which I suppose the lo fellah would call them patchwork and so they are and so's ourselves and the beautiful fields and the pretty ships and the evings. But I aint a goin to fite for Mr. Robbingson seein he's so clever and can do it hisself for it would be a liberty but I hope he will. Fairplay's a juel as the young uns say and she speaks truth there are men who alwys quisses everythink noo speshally us wimen, for how the twopairback did quis my noo kriloneem the other day. Mr. Holdsworth is very a musin. They say "There's corn in Israel" but I think there's charf two. Milly is quite well agin and Jim's a comin ome from see next weak. Hoppin you and yourn are well and feelin grateful for favours conferred.

I remain, Sir, Yrs respekfeately

PENELOPE ANN SPRIGGINS.

P.S.—In case any of your female readers is affected with spassums the twopairback ses that the pizun he giv me was sakrated sperit of jupiter to be mixt with half water jist off the bile and two or three lumps of shuger but if two much is took it as orrid effect on people makin em lose there feet and legs and corsin· em to sea dubbel and all manor. Kitch me a cleinin out his cupboard agin he shall jist do it hisself I aint a goin to loze my legs for nobody. P. A. S.

[We are not surprised at the indignation of Mrs. Spriggins; we had some doubts about the genuineness of the letter of which she complains, as the handwriting did not at all resemble her own aristocratic scrawl.—ED.]

ANSWERS TO CORRESPONDENTS.

MARIANNE.—Solomons, Red Lion Square.

ROBERT L.—Not worth publishing; they lack vigour.

R. S.—Add a little more acetic acid, say ten minims to the ounce of solution.

J. M. C.—We are obliged for your good wishes. We have seen the specimen which you name, it is *not* good, as you say.

J. W. N.—We have not yet arrived at an instantaneous dry process. The malt process, or the Fothergill, will answer your purpose.

MARK.—We are obliged for your communication, but as we have already seen it in a contemporary under another signature, we must decline it.

WM. NEWTON.—You have used too great a glare of light. Shade one side of your sitter, or you cannot get half-tone.

AN IMPATIENT OPERATOR.—We know of no such person as you are seeking. Try M'Lean, Melhuish and Co.

CALOTYPE.—We shall most likely have to announce shortly the plan that will suit your views exactly.

JEMIMA M.—Hear both sides of the argument; the truth will always prevail in the end.

FREDERICK SIMPSON.—You have put too much acetic acid in your developer: with gallic acid you need not use any for some plates.

ROBERT HULETT.—See reply to "J. H. W." Send a list of names and we will indicate by number what you want to know.

IN HASTE.—Many correspondents are like yourself—want an early reply, and send their letters *too late* to have one in the following number. You cannot do what you inquire about.

W. H. H., jun.—There is nothing so small published as you wish for; in fact you have named the whole of the periodicals. Mr. Hockin's manual would perhaps suit your purpose.

C. C. W.—OLD SUBSCRIBER.—1. It is possible that water might be rendered unfit for developing and sensitising solutions by passing through leaden pipes. 2. Add solution iodide of potassium, or of hydrosulphate of ammonia; the first would produce a yellow, the second a dark coloured precipitate. 3. By distillation.

SCRUTATOR.—We stated in our leader that there was *nothing new* in the paper to which you refer—why then are you surprised to find the statement correct? Can you point out any single instance in which we have mislead our readers with regard to facts? We did not assert that there was nothing true, though we must admit that there are some things untrue.

J. H. W.—We cannot recommend by name any special maker of lenses: it would be regarded as unfair by the dealers not named. For good second-hand ones you can safely apply to the party you have mentioned. For our opinion of Derogy's lenses you can consult a back number in which we reported upon them from a careful examination by request of the agent here. The camera must depend upon the lens and the price you are content to give for it. The cheap French walnut wood cameras answer very well for portraits.

GREEDY CHAP.—Probably the collodion has something to do with the unpleasant blueness of which you complain. Try another sample. You will find a formula for a nitrate bath in the back numbers of this Journal, or in any shilling manual of Photography. There is not much difference of opinion as to the proper mode of making a bath, and hence you may avail yourself of any published formula you may meet with. GREEDY CHAP will be obliged if Mr. M'Adam will give particulars how to prepare the electric light as used by him to exhibit transparencies in the magic lantern; how many cells of Bunsen's battery are necessary; and if any danger attends their use?

"PALMAM QUI MERUIT FERAT."—1. The lancewood spring rail for the drying-frame does *not* stain the plates—it merely touches the extreme angle. 2. You do not give any data whereby we can decide the probable cause of your not getting good portraits: in what respect are they "bad"? 3. Protosulphate of iron fourteen grains, nitrate of potash ten grains, distilled water six and a-half drachms, acetic acid (Beaufoy's) one drachm, alcohol half a drachm, will make a good, flowing, positive developer. 4. The speck in your lens is *not* of the slightest consequence. 5. For views the camera should be very nearly level: for portraits we prefer it so likewise, but many operators make it "look down" a little; but in our opinion this gives an undignified aspect to the sitter. 6. You cannot do better than adopt the toning process you name.

FIXED.—We have never tried the special kinds of collodion named by you, but have no doubt they are equal to the average of those in the market. Your mode of developing is good in experienced hands, but not so in those of a tyro; because he never stops the action of the iron developer soon enough. We recommend you to try the following:—

Pyrogallic acid	2	grains.
Distilled water	$7\frac{1}{2}$	drachms.
Glacial acetic acid	$\frac{1}{2}$	drachm.

The alcohol is superfluous and objectionable in this. Expose longer than you have hitherto done by about one half your usual time; pour on of the above sufficient to cover the plate at once, but not more; keep the liquid flowing and you will find the image appear slowly; carry on the action until the intensity appears very great, but arrest the action before the shadows are fogged. Wash well and fix with hyposulphite of soda, and again wash thoroughly.

BOTHERING AMATEUR.—Coat a very clean plate with any negative collodion suited for the dry processes, sensitise as usual, and wash the plate in a dish of distilled water, *but not too much;* then pour over the plate some linseed tea prepared in the following manner:—Linseed half an ounce, hot water one pint, mixed in a clean earthen teapot, keep hot before the fire for half an hour, strain through a piece of sponge placed in the neck of a funnel; when cool it is ready for use. After the film is evenly coated with this liquid set it up to drain, and then dry by aid of heat in a proper drying box. A number of plates may be thus rapidly prepared which retain their sensitiveness for a considerable time. The surface, after drying, is perfectly free from stickiness, and so does not retain any particles of dust that may come in contact with it. If the film should crack it is a sign that the liquid is too thick for the sample of collodion employed, and it is then only necessary to dilute the linseed tea. This preservative liquid should be prepared fresh when required. Wash the plate in a dish of distilled water before developing.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 122, Vol. VII.—JULY 16, 1860.

In our issue of the 15th ult., we casually alluded to the paper read by Mr. Dallmeyer at the closing meeting for the season of the Photographic Society, intimating our intention of returning to the subject on a future occasion. There are several reasons why we do so now, amongst them certain enquiries which we have received, soliciting information relative to the alleged improvements introduced into the photographic objective by the author of the paper mentioned. Questions of this kind are much more easily asked than answered, especially when it must be admitted that a claim has been set up for that which we see clearly enough cannot be established. That certain claims were made in the paper itself will be seen from the following quotations, which we extract from the official report of it in the organ of the Photographic Society, viz.:—"The portrait lens, as constructed and left by my late father-in-law, though it has been used with diaphragms, was not intended for such a purpose, *and, therefore, required reconstructing*," &c. Again:—"If it should be found that the instrument which, in the hands of my late father-in-law, attained so great a measure of perfection *has been still further improved* and rendered more extensively useful," &c.

It is very true that after the reading of the paper, which gave little or no information whatever relative to the nature of the alleged improvements, we find, during the ensuing discussion, that the author expressed himself thus:—"With reference to novelty I claim *none*." But this was not until it had been pointed out to him that some of the mechanical conveniences noticed as new, by implication, had been previously in use by others for several years past, while the extracts from the paper and that from the statement during the discussion appear to us as totally irreconcilable with one another.

There is one paragraph in Mr. Dallmeyer's paper with which we cordially agree, and which we heartily wish photographers more generally understood. He says:—"Strictly speaking, depth of focus means a *general want of focus*." This is a point upon which we have insisted repeatedly, and it will be much to the advantage of our art when its votaries cease to choose lenses for the very quality which brands them with an indelible stigma of inferiority. Mr. Dallmeyer says rightly enough that the only correct remedy for the inconvenience arising from objects being situated at widely differing distances from the lens is in the use of a sufficiently small diaphragm: he, however, lays too much stress upon the aberration from diffraction, due to the supposed use of *too* small a diaphragm by operators—an error very unlikely indeed to occur, for before this limit could be reached, it would be next to impossible to see to "focus," from the necessary enormous reduction of the amount of light transmitted. It would have been advantageous if the author had stated what he regarded as a minimum diameter of aperture in terms of the ratio of the focal length of the lens employed. Upon this point we can offer some incontrovertible evidence. The late Mr. Samuel Buckle, who generally adopted the calotype process, and therefore required a longer exposure than those who employ collodion, usually made use of stops with very small aperture. Some of his productions we have in our possession, and more beautiful pictures of their kind it would be difficult to procure. For the general excellence of his works, we need only point to those which found a place in the Great Exhibition of 1851, and in some of the earlier collections exhibited by the Photographic Society. Some of the very best of these were taken by a lens of nine inches focus, of the ordinary meniscus form, made for him by Mr. Thomas Ross, and with which he employed diaphragms with apertures of one-fifth and one-eighth of an inch respectively, consequently as small as *one forty-fifth part*, a one *seventy-second part* of the focal length, and these certainly were not impaired by any aberration from diffraction. These proportions are, however, much smaller than are at all needful, except, perhaps, in some extreme cases—one-twentieth to one-thirtieth part of the focal length being those most generally useful—for it is found in practice that, by attenuating the pencil to an excessive extent, a weakness and want of vigour in the resulting image is apt to occur.

Want of experience in the art of photography probably tends to mislead Mr. Dallmeyer with regard to the stops, for it must be borne in mind that this is not exclusively an optical question; and he will find that for general landscape work, where parts of the subject necessarily lie in very widely-differing planes, sufficient definition will not be obtained with a large aperture, especially if a large angle of view be included, so that for the purpose indicated the proportions above named will generally find most favour. He appears to imagine that there is some originality in arranging his stops, so that "counting from the largest to the next size smaller, the time of exposure required to produce a picture is doubled, whereby," he says, "much time lost in computing and experimenting will be saved." With regard to this arrangement it is a very common practice; and *he* surely must know that it was adapted by Mr. Thomas Ross to his father's lenses, many years since. As to the assertion relative to loss of time in experimenting, &c., we do not perceive any greater difficulty in reckoning an increase of time by arithmetical than by geometrical progression; and it is a fact that some operators imperatively demand a more delicate gradation than is afforded by the latter.

We now come to the question of *position* of the diaphragms, and the resulting distortions or freedom therefrom—a question which we have more than once discussed in these pages; for instance, in Vol. II., New Series, pp. 163 and 164, 1st July, 1858; also in Vol. VI., p. 222, Sept. 15, 1859. The use of diaphragms between the lenses of the portrait combination ensures freedom from perceptible distortion, owing to the fact that the displacement in one direction by the front lens is counterbalanced by an equal, or nearly equal, displacement by the back lens, but in a contrary direction. The use of diaphragms in this position is as old as the first portrait combinations made by Mr. Andrew Ross; but Mr. Thomas Ross afterwards found, when copying daguerreotype pictures, that the field was flatter with

the stop placed in front of the anterior lens. From that time they have been employed by photographers in either position, according as freedom from distortion of the image or flatness of field were of the greater importance for the work in hand.

It has been very gratuitously assumed by the author of the paper from which we have already quoted that "flatness of field is one of the greatest requisites" in taking views, and that the portrait lens as left by the late Mr. Ross is not adapted for landscape work, because with the diaphragms between the lenses the field is not so flat as when they are placed in front of the combination. We have no doubt, from the above statement, that the author has not been accustomed to take landscapes at all, or he would scarcely have come to any such conclusion. Very few views have all the objects in one plane, or anything approaching thereto. It not unfrequently happens that the principal objects are located in a curve convex towards the lens, still oftener concave with regard to it; and in either case the treatment required resolves itself into a matter of focussing and stopping down the lens to meet the conditions of the case. Flatness of field, then, for an ordinary landscape combination is by no means a quality of such paramount importance as to induce the sacrifice of other important excellencies to obtain it. We value flatness of field as much as any one; but as gold may be bought too dearly, so also are we not content to obtain flatness of field at the expense of lateral definition—the sacrifice which Mr. Dallmeyer appears to have made for it, judging both from his own statements and from the specimen pictures exhibited by him. He says:—"I have approximated to a mean between astigmation and roundness of field;" and the specimens exhibited clearly demonstrated that considerable astigmation of the lateral pencils was suffered to remain uncorrected in order to obtain the flatness of field. For those unacquainted with the subject we may state that "astigmation" may be recognised by the want of definition in the lateral parts of the field. In all of the double combination lenses made by Mr. Ross that have come under our own immediate notice the lateral pencils have been beautifully corrected. Nor is that to be wondered at; for it would scarcely be credible that one who had for many years previously devoted his scientific skill and energies to the perfection of the microscope objective should have been contented with a lens in any considerable degree deficient of definition. Instead, therefore, of regarding the alteration made in Mr. Ross's lens (which, by the way, we may remark, is not the result of one form taken up and persisted in, but the gradual growth of slight variations dictated by practical experience) as any improvement, it is clear that it is nothing more than a shifting of the burden from one shoulder to the other.

That the old Ross portrait lenses have been used for views successfully will be sufficiently evident to those who remember some landscapes taken by the Rev. Dr. Holden, and shown at the exhibitions under the auspices of the Photographic Society. The pictures to which we make allusion were upon plates ten inches by eight inches, unobjectionable, and taken with a three and a quarter inches portrait combination.

The truth is, Mr. Dallmeyer has attempted to produce a lens which is intended to be a sort of optical *Admirable Crichton*—to do something of everything, but nothing perfectly. There are some things which it is quite impossible to unite in one article, so as to perform both functions properly—*e. g.*, a teetotum and a turn-up bedstead. Perhaps photographic lenses may be included in the same category: at any rate we would warn our readers that, when the front combination of a portrait lens is constructed so as to be applicable for separate use as a landscape lens, if the portrait arrangement be upon the best known construction, the front part will make but an indifferent view lens alone; or if it be good as a view lens, then the portrait combination arrangement can be but a makeshift.

There is one paragraph that is totally incomprehensible as it is given, we mean that relating to a large angle of field being equivalent to a lens of shorter focus, and therefore quicker than ordinary lenses, and in stating that because it includes an angle of 50° that it is 10° more than is taken by the forms of lenses previously alluded to (meniscus and orthoscopic). The author commits an error which would have been probably avoided had he read the previous number of the *Journal of the Photographic Society* to that in which his paper appeared; for in the record of the previous meeting of the Society it is stated "that a print of *Trinity College, Dublin*, was exhibited, including an angle of *upwards of* 60°, from a negative taken with one of Mr. Grubb's lenses." Were we not apprehensive of testing our readers' patience too severely, we could point to several more misleading assumptions. As an optician the author may know very well what he is about—as an acute business man he certainly does; for has he not managed to obtain from our worthy brother editor a gratuitous advertisement in the pages of the Society's organ under the guise of a "paper?"—but as a photographer he has much yet to learn.

The paper upon which we have been descanting reminds us of the celebrated criticism published in the pages of a literary journal noted for its sarcasm, which ran somewhat after the following manner:—"Mr. * * * complains that we have not noticed his book: he had better have been contented with our silence. We have perused the book, and find that everything which it contains that is true *is not new*, and everything in it that is new *is not true*."

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 8.

Each new suggestion for the better intensifying of negatives receives our careful attention, because we are convinced that a process of this kind is at present a desideratum. Some long time ago the iodide of arsenic was spoken of, in connexion with the proto-iodide of iron, as an accelerator; but we did not then give it a trial, since it appeared doubtful whether any similarity existed between the two substances thus associated. Iodide of iron is an absorber of oxygen, and produces a developing agent, viz., protonitrate of iron in the bath. Iodide of arsenic, on the other hand, liberates nitric acid in the bath, and ought to retard reduction. Theoretical considerations, however, must sometimes be neglected in photography, and hence, on finding the subject again brought forward, and this time in a new light, we determined to investigate it.

A convenient method of obtaining the iodide and bromide of arsenic is by shaking up a recently-prepared alcoholic solution of iodine and bromine respectively, with an excess of finely-powdered metallic arsenic, until the solutions cease to colour a mixture of starch and iodide of potassium. A few minutes' agitation suffice to produce the result; and the liquids may then be allowed to subside, and the upper part decanted for use. Prepared in this way they are free from arsenious acid, and do not produce any milkiness in collodion made with anhydrous spirits. The addition of water, however, produces immediate decomposition, and arsenious acid is thrown down. Diluted alcohol has the same effect.

The collodion employed in the experiments was iodised with cadmium, the pyroxyline having been made purposely in weak acids, so as to give a maximum of sensitiveness but a small intensity. This preparation was found on trial to be so rapid in its action that, with a whole-plate portrait lens, a negative could be obtained in the open air in about two seconds, or in the glass house in six seconds, the developer being pyrogallic acid solution of the usual strength. The test object for the experiments consisted of a white bust, with a dark stuffed bird well shaded by drawing the curtains around it; and to reduce the light still further, the smallest diaphragm but one of the Waterhouse set was introduced. The following were the results:—

With the simple collodion, and a rather old bath in good condition for yielding intense negatives, the exposure was thirty seconds. The negative appeared full of fine details; even the darkest feathers of the bird being clearly distinguishable from the back ground. The intensity, however, was decidedly insufficient, and not only so, but there was an evident aspect of *halation* or draining downwards from the head of the statue, also a want of sharpness over the whole picture, with a few white spots and a transparent curtain mark at the bottom of the plate.

Taking a portion of the same collodion, the iodide of arsenic was dropped in cautiously until the colour became lemon-yellow, and thirty seconds were given as before: this picture, however, was a failure from under-exposure. To a second portion of the same collodion the bromide of arsenic was then added rather more freely; in half-an-hour the tint became that of brown sherry. The light remaining nearly the same, thirty seconds were again given, and the pyrogallic acid developer applied as before. This time the success was better, for the bust developed of an inky blackness, and many of the details came gradually out. On fixing the negative, and bringing it to the light, the appearances were these:—The amount of detail was evidently less than in the first negative, inasmuch as the darkest feathers on the neck of the bird could not be distinguished from the sombre tint of the back-ground. The statue, however, appeared to be as much exposed as with the simple collodion. As regards intensity, the difference was more decided by reflected light than by transmitted light, and appeared to consist rather in colour than in actual thickness of deposit—the arsenic negative being smoky or brownish-black, the simple negative of a violet blue. One point, however, in the arsenical negative appeared satisfactory—it had in great measure those peculiarities which are found in a bromised collodion, viz., sharpness and decision of outline, absence of halation, absence of white spots, curtain marks, &c.; so that, on the whole, the arsenical negative was deemed the better negative of the two.

Being satisfied thus far, we continued the experiments by opening up the aperture of the lens and working with a full supply of light, five seconds' exposure being allowed. The results confirmed the preceding—the simple collodion being superior as regards rendering the very darkest parts of the object, but the collodion containing the bromide of arsenic giving the most smoky negative and the best definition. Upon the whole, the advantage of using the arsenical preparation was less evident in these experiments than in the last, since the simple collodion gave enough intensity without any addition when the development was sufficiently pushed.

Leaving the collodions we then proceeded with the bath. The solution of iodide of arsenic, mixed with a little nitrate of silver, threw down iodide of silver, and developed a strong acid reaction. This had been anticipated, because there exists no oxide of the metal arsenic capable of neutralising nitric acid and producing a soluble nitrate; hence the effect is much the same as when *iodine* is added to nitrate of silver, only that in the former case you have arsenious acid, in the latter an *iodate* in addition to the nitric acid. Taking the whole of the bath solution in which the previous experiments had been made, iodide of arsenic was dropped into it until it became quite opalescent from suspended iodide of silver, and a piece of immersed litmus paper slowly reddened. After filtration pictures were taken on a simply iodised collodion, and with tolerable success. The exposure required was longer than in the case of a pure bath, but by allowing more time a picture could be obtained. The negatives taken in this bath had not the characteristic smoky tone of those before referred to, but resembled simple collodion negatives. Finding that the bath had not been hopelessly ruined, we next shook it up with arsenious acid (as much of the powder as would stand upon a sixpence), and repeated the experiment. The result was, that a picture came out, but it lacked detail, and was foggy in the shadows. Lastly, we dipped the arsenical bromised collodion into the same bath. This negative turned out well, and was free from fog.

Many other experiments have been made besides those mentioned above; and our present impressions are as follow:—Iodide of arsenic added to a simply iodised cadmium collodion of the most sensitive kind, the developer being diluted pyrogallic acid, diminishes the sensitiveness, and that to an extent sufficient to prove an objection to its use. Bromide of arsenic in cadmium collodion undergoes a double decomposition, bromide of cadmium and iodide of arsenic being formed: this preparation possesses many of the advantages of a bromised collodion, and gives a more smoky colour of the image in the high lights. The nitrate bath is not very quickly affected, and will remain in order for a long time if a bromised collodion be used. Both the iodide and bromide of arsenic exert a slight gelatinising action upon the collodion. The effect of these arsenical preparations is not unlike that of the protochloride of palladium, used as an intensifier, and is less decided than the effect of glycyrrhizine, or of pyroxyline made purposely for giving intense negative images. In all probability the smoky colour of the arsenical image is due to the silver being partially alloyed with arsenic, and the principal reason why it appears to develop with so much force in the first instance, is because the image, being superficially darkened, contrasts well with the surrounding yellow iodide.

ON THE PREPARATION OF POSITIVE PAPER.

By M. Aleo.

I. PREPARATION OF THE ALBUMEN.

Break the eggs into a graduated measure, taking care not to contaminate the albumen with the yolk, and, when the requisite quantity is obtained, separate the germs and pour the whites into a glazed porcelain basin; and to every one hundred parts add five parts of a soluble chloride (hydrochlorate of ammonia, chloride of sodium, or chloride of barium*), previously dissolved in the least possible quantity of water. The quantity of water must not exceed one-tenth of the albumen, if it is wished to obtain proofs of great brilliancy. Beat into a thick white froth, and after five minutes' rest, remove the froth with a fork, and throw it on a hair sieve, which should be placed in a second basin. Gradually beat all that remains in the first basin, until all has been coverted into thick froth and strained through the sieve. Leave the froth to settle for twelve hours, and the liquid that flows through is ready for use. When the paper is prepared, place a basin with a glazed bottom so that it is quite horizontal. Into this filter the albumen by means of a small fine sponge put into the neck of a glass funnel. Albumen that has rested for a few days is much better for use than that newly prepared. M. Aleo advises that the bath should be filtered into a basin about twelve hours before it is used, and to keep it carefully covered. In fact, the albumen settles and purifies itself like collodion. If we attentively examine a basin containing a bath recently filtered, we find on its surface a quantity of small floating particles resembling little drops of coagulated albumen: to these are attached long threads of albumen, and a sheet of paper placed on such a bath takes up this bleb and thread when removed. If, on the contrary, the bath has had time to rest, all the impurities settle down and become harmless.

II. PREPARATION OF THE PAPER.

The positive paper must be carefully selected and tried previously to preparing any quantity. The paper must have been sized with the greatest care, or else it will look spotty, be devoid of brilliancy, and give imperfect results. In order to cut it to its proper size, put it down flat, and make use of a ruler and a very sharp point. By using a paper or other knife, or by folding the leaf, inequalities will arise, and the albumen, being retained in these places, will flow unequally, and thus produce all over the sheet marblings and other stains. Having marked the back of the paper, place all the leaves one upon the other, and then proceed to place them on the albumen bath. For this operation we must choose cool, and especially damp, weather. When this is the case the paper is yielding, a little moist, and consequently sticks to the albumen bath by cohesion, and without any bubbles; when, on the contrary, it is dry, its surface is hard, which prevents the albumen from flowing easily, and hence a great many bubbles; the paper also dries more slowly, and, consequently, we may be prepared to see the upper part of the leaf quite dry, while the lower part is still impregnated with albumen, which would cause ring-like marks. The first leaf is almost always imperfect, and, in fact, should only be used to cleanse the surface of the bath.

To lay the sheet on the bath, begin by making two small folds, turned up at the angles; take it by the upper angle, hold the lower angle, and place the lower part of the sheet on the bath, on the side of the tray which is nearest to the operator, and continue to lower the sheet in a bent position, and following the movement of the wave of albumen, which must flow slowly to the other end of the paper; whilst doing this, care must be taken to go on regularly, and particularly to avoid lifting up a part already wetted, for at each stoppage we should find a film of albumen which, being partly on the leaf and partly in the bath, might spoil the sheet in preparation, and also the one following.

There will be a time when some difficulty will present itself, namely, when the leaf can no longer be bent; it then falls flat on the bath, and touches in several places on a broken-up surface, which will be the cause of bubbles. This inconvenience we can easily avoid by slowly dropping the leaf on the bath, and pressing slightly with the fingers on the back of the paper.

The time for laying on the bath, which may vary according to the thickness and sizing of the paper, is on an average two minutes and a-half. It is always necessary to wait till the sheet has quite flattened out, as it often curls up the contrary way, especially if

* Frequently the chloride of barium, crystallised in an acid liquid, partially coagulates the albumen; and, after its preparation, produces a turbid liquid, which will nevertheless give good results.

thick and strongly-sized paper is employed. After the time mentioned, take the leaf by the two corners which have been made before laying it on the bath, and thus lift it up with a slow and regular movement, and in this way the albumen flows in a continuous even coating from the upper to the lower angle, and it is then suspended with all the precautions given in section 3. It will be seen that by this way of operating the sheet is laid on the bath, lifted up, then suspended in its greatest breadth in such a manner that there is the least possible distance between the upper and lower part of the sheet, and consequently less chance of its drying in zones.

III. SUSPENSION AND DRYING OF THE PAPER.

The mode of suspending and drying the paper is one of the most important points, in order to avoid unevenness, and the following means have been used with invariable success, and without the least difficulty:—Take two strong cords, commonly called whip-cord: begin by waxing them well, in order to avoid in the movement of the sheets the detachment of dust, which would cause spots; on to each of these cords string an equal number of little squares of thin cork, about one and a-half inch square, having in the upper part, and nearly at the same point, a hole large enough for allowing the corks to run freely on the cord. The latter are placed parallel, and by means of three small wooden bars, fixed, one in the middle, and the others at the two ends of the apparatus, they are kept asunder; care must be taken that the distance is about two-thirds of an inch greater than the large side of the sheet of paper. This apparatus is now fastened to the opposite walls of the room in which the operation is performed; the cords are stretched tightly, quite horizontally, and a little higher than the height of the head. Through all the corks on the same side, on the right for instance, a varnished steel pin* is run obliquely, the point of which must stick upwards towards the operator, and incline towards the exterior side of the cord on each cork; on the left another pin is stuck, which will thus be found at hand at the moment it is wanted.

These arrangements being completed, carry the sheet, which must always be kept in the same position, to the suspending apparatus; present the right angle of the leaf to the steel pin, lightly pulling it with the left hand, and without any pressure the very sharp point will immediately penetrate it; the oblique position which has been given to the pin will be sufficient to hold this corner of the leaf. Then stretch out the paper towards the cork on the left, and fix it there with the second pin, taking care, however, to place it so that the upper part of the sheet is completely stretched out; in fact, if care be not taken to stretch the leaf completely, it will soon form a curvature, which will again be the cause of unevenness of surface. In this manner the albumen flows down quite regularly in a sheet, and accumulates at the bottom of the sheet, whence it is made to fall by the passing over it, from time to time, of a stiff stick, which scrapes the lower edge. This albumen is received into a basin, and may be used again after having been filtered. We must not allow the albumen to flow off at a single angle, by inclining the apparatus even very slightly towards one side, for this inclination may produce a horn-shaped scroll at the highest corner, and be again the cause of unevenness and spots.

There should be three or four suspending arrangements put up parallel by the side of each other, and to these the sheets of paper should be suspended in succession one after the other; thus the dripping of the albumen can be more readily observed, for it would be found very troublesome if the leaves were suspended immediately one over the other. When the leaves are getting dry, put them closer together; lastly, put them into the positive pressure frame, in order to smooth them again.

The suspending apparatus, as explained above, besides perfectly answering its purpose, has this great advantage, that it is not at all bulky, but it may be put up and taken down again with the greatest ease, and it allows a great number of sheets to be hung up at the same time; in fact, the length of 39 inches is sufficient for extending ten sheets at a time.

The formulæ are those which are generally to be found in treatises on photography, but up to the present time no one has given the whole of the precautions which must be taken, and these have only been discovered through a series of failures, which had to be rectified as they occurred, and it is therefore thought that these notes may be useful, if the minute descriptions given of each operation do not weary the amateur.

* Varnished steel pins are preferable to varnished brass pins, because the former do not get so easily blunted.

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING THE PHOTOGRAPHIC IMAGE.*

Report of the Committee, consisting of Messrs. Maskelyne, Hadow, Hardwich, *and* Llewelyn.

The chemical problem presented by the photographic image is one of great complexity. It is uninviting to the chemist in so far as it presents very little opportunity of his obtaining quantitative results; for howsoever subtle and rapid be the chemical transformation effected by the light, it consists, in most cases, of a superficial change only, and defies even the delicate methods of the balance. In undertaking to collect what is known and to test the correctness of what has been published regarding this intricate problem, the Committee have proposed to themselves to deal first with the simplest transformations on which photographic processes are founded, and to pass on from these to the more complex.

Moreover they confine themselves to the photographic results obtained with the salts of silver, as these are the most employed, and because it is necessary to assign some limits to their inquiry.

If the salts of silver are the most remarkable for their susceptibility to photochemical change, one is naturally led to search first for the causes of this among those simpler compounds of the metal in which the transformation is not complicated by the secondary decompositions which might be expected to accompany it in the case of organic compounds. Yet among the inorganic compounds this susceptibility to photochemical decomposition is rare; and though not absolutely confined to one salt, the chloride of silver, that body exhibits the simplest and one of the best illustrations of it.

The chloride of silver, when perfectly pure, passes, on exposure to light, from its pure white through various stages of change in hue, in which blue is mixed with grey, until it finally reaches a deep slate-violet colour. Chlorine is evolved from the chloride; but the question which here meets us *in limine* is one which probably underlies the whole of the problem we have to consider, and consists in the chemical condition in which the silver remains after the light has completed the decomposition so far as it can go. Is the result a subchloride of silver? or are the chlorine and the silver completely dissevered, the gaseous element going away, and the metal remaining mixed with, or rather encrusting, particles of unaltered chloride?

Certainly the weight of authority is in favour of the latter view. Such, at least, is to be gathered from papers by Dr. Draper, of New York,† by Mr. Guthrie,‡ and more recently from a series of papers by MM. Davanne and Girard, in France.

In the first two memoirs referred to, an allotropic state of metallic silver is viewed as the only explanation of the reactions of the dark substance formed by the light. No chemist, however, has yet produced this substance in such a state of purity as to be able to subject it to analysis; and the only arguments, therefore, which can be relied on in explanation of the change are such as make the fewest assumptions and put the least strain on the present experience of the chemist.

There have been many methods proposed for the production of a sub-chloride of silver by processes directly chemical. One of these consists in the suspension of silver leaf in a dilute solution of sesquichloride of iron, or of chloride of copper. But this experiment has been repeated by us, and we are compelled to look upon the purple-tinted product as chloride of silver accompanied by but a trace of a substance possessing a profoundly colouring power, which, as will presently be explained, we believe to be a sub-chloride.

In order to produce this substance with at all events a greater approach to isolation, we endeavoured to avail ourselves of the possibility of a reaction between chlorhydric acid and the suboxide of silver, and with this view instituted many experiments for the production of this last body in a state of chemical purity. Memoirs devoted to the chemistry of the suboxide of silver are not rare. Professor Faraday§ showed that the deposit formed by the exposure to the air of an ammoniacal solution of oxide of silver, consists of a compound with a composition of 108 silver and 5·4 oxygen. This composition is incompatible with a formula Ag_2O (supposing oxide of silver to be AgO); but the physical characters of the body are interesting. It is grey, and by reflected light is seen to possess a strong lustre. By transmitted light a thin layer of it appears bright yellow.

* A paper read before the British Association, 1859, and extracted from the official report, just published.

† Phil. Mag. xiv. 322.

‡ Chem. Soc. Quart. Journ. x. 74.

§ Quart. Journ. Sc. iv. 268.

Rose* has called attention to various other reactions in which suboxide of silver appears to be formed. Thus, if ammoniacal solution of nitrate of silver be added to protosulphate of iron, a deep and intensely colorific black precipitate is formed, consisting of a compound expressed by the formula $Ag_2O, 2FeO, Fe_2O_3$. Similar or analogous products of different composition are formed by the use of salts of the manganous oxide, and by solutions of cobalt; but in all these cases the suboxide of silver is associated in combination with other bodies, and does not present itself in a state from which it would be easily convertible into subchloride. Rose, indeed, has made one remark, in connexion with these researches, which has a significance of some value for the photographic chemist. He shows that, in the case of adding the acetate of silver to a protoacetate of iron, the precipitate presents the black tint and deeply colorific power which seem to characterise the compounds of the suboxide of silver. When the salts used, however, contain "strong" mineral acids, as when nitrate of silver and sulphate of iron are the mutual precipitants, the deposit is grey and metallic—the reduction of the silver is, in short, complete. The significance of this fact we shall hereafter recall.

(To be continued.)

TREATMENT OF OVER-PRINTED POSITIVES.

By M. Vernier, Jun.

Over-printed positives which are usually regarded as spoilt, and positives obtained from over-developed negatives, may be made available by treatment in the following bath, which reduces the depth of colour, and produces a general harmony :—

Cyanide of potassium	15 grains.
Water, ...	1 pint.
Liquor ammonia	1½ drachms.

After the over-printed positives have been toned, fixed in hypo., and well washed, they are put into this bath one at a time, and allowed to remain for four or five minutes, according to their intensity, and until the details in the shadows come out

During the operation the bath should be covered in by a close-fitting sheet of glass to prevent the escape and inhalation of the fumes of prussic acid given off. The solution must not be used a second time.

British Association.

OXFORD MEETING, 1860.

[FROM OUR SPECIAL REPORTER.]

The British Association for the Advancement of Science held its thirtieth annual meeting this year at Oxford, being the third time that the Association has met at the *alma mater* of many of its eminent founders.—The first of the recent series of meetings took place on Wednesday, the 27th ultimo, in the Sheldonian Theatre, which was crowded by richly-dressed ladies, and by English and foreign members and associates. At this meeting, H.R.H. the Prince Consort, in a few graceful sentences, resigned the Presidency in favour of the new president, Lord Wrottesley, who then delivered the annual address—a profound discourse, in which the progress of science during the previous year was elaborately reviewed. The closing meeting was held in the same Theatre on Wednesday, the 4th instant, when the adjournment took place.—The next annual meeting of the Association will take place at Manchester, in August, 1861.

Distinguished as Oxford is by its noble old colleges and halls, observatory, museums, libraries—to say nothing of its varied literary and scientific associations, ancient and modern, and its natural beauties—the late visit of the Association to this delightful city was looked forward to with unusual interest by the eminent in science, art, and literature, and by those migratory members who follow the Association in its periodic wanderings throughout Great Britain and Ireland.

While the late meeting had many points of interest for the visitors to Oxford; while the learned dignitaries and professors of the university dispensed their hospitalities to as many as the colleges could accommodate; although the magnificent new Museum in its architectural beauties vied in splendour with the brilliant company which, night after night, graced the *conversazioni* held within its ample precincts; and while the more distinguished *savans* were entertained at refined and charming receptions,—it must be confessed that, to the general body of members and associates, the meeting at Oxford was "slower" than they have been of late years accustomed to. That there were numerous papers of importance read at the recent meeting none can deny, and the interest of Section E (Geography and Ethnology) especially was well sustained by the presence of a large number of world-famed Arctic voyagers; still, the list of papers which appeared day by day in the *Journal of Sectional Proceedings*, failed to impress the more thoughtful of the members with the idea that the majority of the subjects brought forward were really calculated to further "the advancement of science"—at least in as great a degree as those of former meetings of the Association held at the marts of commerce and the homes of our great manufactures.

In one or two of the Sections the personal element formed an item to give animation and piquancy to the discussions; and few who were present will soon forget the "passage of arms" which took place at the Saturday's meeting of Section D (Zoology and Botany, with Physiology), between the Bishop of Oxford and Professor Huxley, on the development theory of Darwin,—which discussion followed the reading of a paper by Dr. Draper *On the Intellectual Development of Europe, considered with reference to the Views of Mr. Darwin and others, that the progression of Organisms is determined by law.* In Section E many discussions took place which brought into activity the intellectual pleasantries of Mr. Crawford, and gave warmth of expression to the remarks of other speakers in that Section.

Our own cause of complaint—or rather of regret—in connexion with this meeting, is that our *progressive* art was scarcely recognised, and that the existence of photography, as a branch of science, was almost wholly ignored at Oxford. In Sections A (Mathematical and Physical Science) and B (Chemical Science), where the followers of our interesting art "most do congregate," only three papers, and those not calculated to "advance" in any appreciable degree the "progress" of *our* "science," rewarded the photographic attendants of the Sections named,—and those papers were read in Section A. Chemical science failed to produce even one paper having relation to photography proper at the meeting at Oxford! The papers alluded to as having a bearing on our specia art were two read by M. Claudet, and one by Dr. Draper, of New York. The subjects of M. Claudet's papers were *On the Principles of the Solar Camera*, and *On the Means of Increasing the Angle of Binocular Instruments, in Order to Obtain a Stereoscopic Effect in Proportion to their Magnifying Power;* and Dr. Draper's was *On a Reflecting Telescope for Celestial Photography, now erecting at Hastings, near New York*, communicated by Professor Draper. We append these papers to this article.

To whom to attach blame for this paucity of photographic papers we cannot at present say. Whether the Association authorities repelled the advances of our amateurs and professionals, or whether the latter displayed a reprehensible apathy in the matter, we are not in a position to determine; but the cause may perhaps be traced to the fact that hitherto Oxford has "made no sign" in the art of photography, except in furnishing to Fenton, Delamotte, and others, subjects of great interest and beauty for the exercise of their artistic ability.

It is true that the noble president, Lord Wrottesley, in the admirable address with which he inaugurated the meeting, has not entirely overlooked our favourite science; for we find the following interesting item of intelligence in his lordship's address :—

> You are aware that at the suggestion of Sir John Herschel an instrument was constructed for the Kew Observatory, to which the name of Photoheliograph has been given, because it is adapted solely to the purpose of obtaining photographic representations of the appearances on the sun's disc. Many difficulties have been encountered in the use of this instrument, but by the zealous exertions of the late Mr. Welsh, Mr. Beckley, and Mr. De la Rue, they have been overcome. It is to the last-named gentleman, so distinguished for his successful prosecution of celestial photography, that the Royal Society have entrusted a grant of money to enable him to transport the Photoheliograph to Spain, to observe the total eclipse of the sun, which is now approaching, and great interest will attach to records of the phenomena of the eclipse thus obtained.

The *conversazioni* at the new Museum (of which there were four) were well attended, and passed off very satisfactorily. At the last *conversazione*, held on Tuesday, the 3rd instant, there was a magnificent display of microscopes and microscopic objects in the centre aisle of the court and in the north library. Among the names of gentlemen who contributed instruments we noticed those of Dr. Bowerbank, F.R.S., Dr. Beale, F.R.S., Messrs. Smith, Beck,

* Journ. Pract. Chem. lxxi. 215, 407 *et seq.*; see also Wöhler, Pogg. Ann. xli. 344.

and Beck; Mr. T. Ross, Mr. Dallmeyer, Mr. Ladd, Mr. Salmon, Mr. Adie, all of London; M. Nachet, Paris, &c., &c.

Regretting that we have so little photographic intelligence to communicate from the recent meeting at Oxford, and looking forward with hope to the period of the next meeting of the British Association at Manchester*—the literary and scientific activities of which city have kept pace with its material prosperity—we proceed to give the few papers connected with photography read at the recent meeting, and thus for another year take leave of the British Association for the Advancement of Science.

We must not omit to mention that Mr. Fairbairn has been chosen to succeed Lord Wrottesley as president for next year. The choice has given universal satisfaction.

* Since writing the above, we find by the report of a recent meeting of the Manchester Photographic Society, in another column, that our indefatigable brethren of the "black art" in the "cotton city" have resolved on having a photographic exhibition during the meeting of the British Association in 1861, for which active preparations have been already commenced.

On the Principles of the Solar Camera.

By A. Claudet, F.R.S.

The solar camera, invented by Mr. Woodward, is one of the most important improvements introduced into the art of photography. By its means small negatives may produce pictures magnified to any extent: a portrait taken on a collodion plate, not larger than a visiting-card, can be increased, in the greatest perfection, to the natural size; views as small as those for the stereoscope can also be considerably enlarged. This is a great advantage, which is easily understood when we consider how much quicker, and in better proportion of perspective, small pictures are taken by the camera obscura, while the difficulties of manipulation are greatly diminished.

There is nothing new in the enlargement of photographic pictures. This has been done long since, simply by attention to the law of conjugate foci; and every photographer has always been enabled, with the common camera, to increase or reduce the size of any image. For the enlargement, it was only necessary to place the original very near the camera, and to increase in proportion the focal distance. But the more the focal distance was increased, the more the intensity of light was reduced; and a still greater loss of light arose from the necessity of diminishing the aperture of the lens, in order to avoid the spherical aberration. Such conditions rendered the operation so long that it became almost an impossibility to produce any satisfactory results when the picture was to be considerably enlarged. For these reasons, it naturally occurred, that if the negative, having its shadows perfectly transparent and its lights quite black, was turned against the strong light of the sun, its positive image at the focus of the camera would be so intense that the time of exposure would be considerably reduced. So that, in order to employ the light of the sun, and follow easily its position without having to move constantly the whole camera, it was thought advisable to employ a movable reflecting mirror, sending the parallel rays of the sun on a vertical plano-convex lens condensing those rays on the negative, placed before the object glass, and behind the condenser, somewhere in its luminous cone.

Many contrivances for this object were resorted to, but without considering anything else than throwing the strongest light possible on the negative to be copied. The constructors of these solar cameras never thought it very important to consider whether the focus of the condensing lens was better to fall before or behind the front of the object-glass, provided the negative was placed in the luminous cone of the condenser. This want of attention has been the cause which has made the solar camera a very imperfect instrument for copying negatives.

The beautiful principle of Woodward's solar camera consists in his having placed the focus of the condenser exactly on the front lens of the camera obscura. As this principle had not yet been explained when the invention was exhibited before the Photographic Societies of London and Paris, and not even by the inventor himself in the specification of his patent, I find some pleasure, in the interest of photography, to bring the subject before the British Association, and to demonstrate that the solar camera of Woodward has solved the most difficult problem of the optics of photography, and is capable of producing wonderful results. This problem consists in forming the image of the negative to be copied only by the centre of the object-glass reduced to the smallest aperture possible, without losing the least proportion of the light illuminating the negative.

The solar camera does not require any diaphragm to reduce the aperture of the lens, because every one of the points of the negative are visible only when they are defined on the image of the sun, and they are so (in that position exclusively), for the centre of the lens is the only point which sees the sun, while the various points of the negative which form the marginal zone of the lens, are defined against the comparatively obscure parts of the sky surrounding the sun—are, as it were, invisible to that zone; so that the image is produced only by the central rays, and not in the least degree by any other points of the lens, which are subject to spherical aberration. It is, in fact, a lens reduced to an aperture as small as is the image of the sun upon its surface, without the necessity of any diaphragm, and admitting the whole light of the sun after it has been condensed upon the various separate points of the negative. It is evident that from the centre of the lens the whole negative has for background the sun itself, and from the other points of the lens it has for background only the sky surrounding the sun, which fortunately has no effect in the formation of the image.

Such is the essential principle of Woodward's solar camera, which did not exist in that instrument when the focus of the condenser was not on the object-glass. This principle is truly marvellous; but it must be observed that the solar camera, precisely on account of the excellence of this principle, requires the greatest precision in its construction. For its delicate performances, it must be as perfect as an astronomical instrument, which, in fact, it is. The reflecting mirror should be plane, and with parallel surfaces, in order to reflect on the condenser an image of the sun without deformation; and in order to keep the image always on the very centre of the object-glass, the only condition for the exclusion of the oblique rays, the mirror should be capable by its connexion with a heliostat of following the movements of the sun. The condenser itself should be achromatic, in order to refract the image of the sun without dispersion, and to define more correctly the lines of the negative; and a no less important condition for losing nothing of the photogenic rays would be, to have it formed with a glass perfectly homogeneous and colourless.

With such improvements, the solar camera will become capable of producing results of the greatest beauty; and, without any question, its introduction into the photographer's studio will mark a period of considerable improvement in the art.

On the Means of Increasing the Angle of Binocular Instruments, in order to obtain a Stereoscopic Effect in proportion to their Magnifying Power.

By A. Claudet, F.R.S.

In a paper on the stereoscope, which M. Claudet read before the Society of Arts in the year 1852, alluding to the reduction of the stereoscopic effect produced by opera glasses on account of their magnifying power, he stated that, in order to redress that defect, it would be necessary to increase the angle of the two perspectives. This he proposed to do by adapting to the object-glasses two sets of reflecting prisms, which by the greater separation given to the two lines of perspectives, would reflect on the optic axes images taken at a greater angle than the angle of natural vision.

Such was the instrument that M. Claudet submitted to the British Association, to prove, as he has always endeavoured to demonstrate in various memoirs, that the binocular angle of stereoscopic pictures must be, in proportion to the ultimate size of the pictures on the retina, larger than the natural angle when the images are magnified, and smaller when they are diminished; which, in fact, is nothing more than to give or restore to these images the natural angle at which the objects are seen when we approach them or recede from them. For magnifying or diminishing the size of objects is the same thing as approaching them or receding from them, and in these cases the angles of perspectives cannot be the same.

M. Claudet showed that, looking at the various rows of persons composing the audience, with the large ends of the opera-glass, all the various rows appeared too close to one another — that there was not between them the distance which separates them when we look with the eyes alone; and he showed also that, with the small end, the distance appeared considerably exaggerated. But, applying the sets of prisms to the opera-glass in order to increase the angle of the two perspectives, then looking at the audience as before, it appeared that the various rows of persons had between them the natural distance expected for the size of the image or for the reduction of the distance of the objects.

By applying the two sets of prisms before the eyes without the opera-glass, it was observed, as was to be expected, that the stereoscopic effect was considerably exaggerated, because the binocular angle was increased without magnifying the objects; but, looking with the two sets of prisms alone at distant objects, the exaggeration of perspective did not produce an unpleasant effect: it appeared as if we were looking at a small model of the objects brought near the observer. By the same reason, stereoscopic pictures of distant objects (avoiding to include in them near objects) can advantageously be taken at a larger angle than the natural angle, in order to give them the relief of which they are deprived as much when we look at them with the eyes as when we look only with one eye; instead of being a defect, it seems that it is an improvement. In fact, the stereoscope gives us two eyes to see pictures of distant objects.

On a Reflecting Telescope for Celestial Photography, erecting at Hastings, near New York.

By Henry Draper, M.D.

In the summer of 1857, after the Dublin meeting of the British Association, a party visited Lord Rosse's telescope, at Parsonstown. We were shown the machinery employed in its construction, and, as far as the weather permitted, its performance.

That visit first led me to attempt constructing an instrument which should be specially adapted for celestial photography, for which purpose the reflector possesses such conspicuous advantages over any refractor.

Those who are familiar with photographic operations know well how important it is for the ensuring of uniform success that the sensitive surfaces should always be placed in similar circumstances as to position, and that position must afford every facility for carrying on the necessary manipulations.

It appeared to me that a modification of a form of mounting proposed some time ago by Mr. Nasmyth could be made to answer these requirements perfectly, and that a Newtonian reflector, sustained on hollow trunnions, through one of which the rays from the small mirror could come, would permit of operations being carried on upon a horizonal table at the end of the trunnion with great ease. Whatever might be the altitude or position of the object the photographic table would always be horizontal.

As I proposed that the telescope should not be less than twelve feet in focal length, an advantage would obviously arise from making the vertical axis of the framework beneath its centre of gravity. The observatory in which it should be placed would then require to be only one-half the diameter that would otherwise be demanded. A twelve-foot tube could be worked with its frame in a cylindrical space, thirteen feet in diameter and thirteen feet in height.

I therefore cast a speculum of fifteen inches in diameter and two inches in thickness. The materials employed were Minnesota copper—regarded in America as the purest commercial form of that metal—and Banca tin. Their proportions were those recommended by Lord Rosse. The cast was made in sand, four inches in thickness in every direction from the speculum, which was permitted to remain for two days unopened, to insure slow cooling. It proved to be perfectly successful. The machine used for grinding and polishing it was that of Lord Rosse.

The tube of the telescope is of black walnut, bound externally by brass rings, and strengthened interiorly by iron ones. The trunnions at the little mirror are of gun-metal: they work on friction rollers of the same substance, supported on polished steel axles.

The telescope is moved in altitude, with the utmost facility, by the aid of counterpoising levers, which act perfectly, whatever the position of the tube may be. The pulleys through which these counterpoising levers work are also of gun-metal, supported on friction rollers, with polished steel axles. The motion, upon a vertical axis, is accomplished by a cast-iron shaft, two and a half feet in length, and three inches in thickness, working at one end on a hemispherical termination in gun-metal, and the other sustained in a strong and ground cast-iron collar.

The observatory in which this instrument is being placed is situated on a hill, four hundred feet above the level of the sea, at Hastings, about twenty miles north of New York.

The edifice consists of a sunken chamber, excavated out of the solid rock. The walls of this chamber are substantially built of stone, laid in hydraulic cement. They are nine feet high. On the top of these walls a lighter wooden edifice is raised sufficient to make the building of the required height. The revolving roof is metallic. The ground plan is square, and seventeen feet in the clear interiorly. As the frame of the telescope only requires a cylindrical space of thirteen feet, the corners of the building are very available for the necessary photographic preparations.

On the top of the stone wall is placed a circular gallery running entirely around the interior of the room, and enabling the operator to have access with great facility to the photographic table and the eye-piece trunnion of the instrument. The interior of the observatory is sheathed throughout with wood.

This partly underground construction has been adopted for the purpose of ensuring a more complete invariability of the temperature of the mirror. A thorough ventilation is, however, secured whenever desirable, the local position of the edifice being such that the door of entrance is on the side of the hill at the level of the floor. The wooden sheathing is for the purpose of avoiding deposition of moisture.

At the moment of writing this paper the building is unfinished, though rapidly approaching completion. The various parts of the instrument and the photographic arrangements are provided, and no difficulty is anticipated.

This is the first observatory that has been erected in America expressly for celestial photography, and it is hoped that, considering the purity of the skies, it will yield good results.

I expect also to derive considerable advantage from the method of darkening collodion negatives by the aid of protochloride of palladium, described by me in a paper read before the American Photographical Society, and which I think in this application will permit of good proofs being taken by unprecedentedly short exposures.

STEREOGRAPHS.

St. Mary Magdalen's Church, Tetbury.

This is an interior taken by Messrs. Dutton, which, though deficient of any but a local interest, is well executed both as regards the printing and the production of the negative. There is a slight curvature in the columns, but this disappears in the stereoscope: the detail and half-tone are both highly commendable, and the proof is of an agreeable tone. The subject, such as it is, has been made the most of.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.*

The following officers have been elected or re-elected for the ensuing year:—

President — Rev. Francis F. Statham, B.A., F.G.S.

Vice-President — W. Ackland, Esq.

Hon. Secretary — Mr. Alfred H. Wall, 90, Cannon Street West, City.

Hon. Treasurer — Mr. Frank Howard, 12, Whittingham Villas, Studley Road, Stockwell.

Committee —

Mr. M. Hannaford.	Mr. N. E. Fitch.
T. Martin.	G. W. Simpson.
A. Herve.	J. A. Cotton.
J. C. Leake.	W. Clarke.

The Secretary hopes that their next meeting — the first in the open air—will be well attended. The usual committee meeting will be held at the Secretary's, in Cannon Street, on the second Wednesday of the month, at Half-past Seven in the evening.

* Omitted in our report of this Society's last pleasant meeting.

Letters to a Photographic Friend.

No. I.

My Dear Thompson,

According to promise I sit down to let you know what is doing in the great metropolis in the way of Novelties at the various Photographic Warehouses; and although I hear bitter complaints of the wet season putting a damper on this branch of trade, and the rifle movement entrenching on cash that would otherwise have been offered up as a sacrifice at the Temple of Sol, still I find ample material to occupy both time and paper in description.

On leaving my friends at Brighton, I made my way to London—not by rail, but by one of the few four-horse coaches that by some "law of natural selection" (as Darwin would call it) has been enabled to hold its own upon the surface of the earth in spite of its puffing, grunting, blustering *mailed* oppressor of the iron way, that displays its native obstinacy by setting at defiance the order of the Directors, that "no smoking is allowed," by smoking its hardest from one end of the line to the other, excepting at such times as it

stops to drink. You know how I love the clatter and dash of four well-appointed steeds as they bowl over old England's country highways ("*may their shadows never be less*," by-the-by), and force one into a closer union with the bracing air of our chalky Downs. During this jaunt I was particularly struck with the manner in which photography has established itself as one of the institutions of this country; for, from the time we left Brighton till the moment of our arrival in London, THE ART was in some form forcing itself upon our attention: now presenting itself as a fashionable "studio" within sight of our coach-office—then as the head-quarters of a pedestrianising member of "the profession," established in the back garden of a village cottage—presently peeping out at the first-floor window, over a tailor's shop, in a market town—anon in the shape of a van, lurking near the entrance to "the Lover's Walk," on the outskirts of a romantically-situated village. Even private houses seemed to be seized with the prevailing photo-mania; for, in a prettily situated cottage, at the foot of one of the celebrated Surrey hills, a glass excresence, of which "the purpose is perspicuous," stared us in the face, even in this retired spot, "far from the busy haunts of man." On asking our coachman the name of this residence, he said it bore the ominous designation of "*La Guillotine;*" and he believed that the proprietor had so christened it "cos it was where people *had their heads taken off*." If Benjamin Webster should ever feel disposed to give a representation of "The Dead Heart" in the neighbouring town of Dorking, he would certainly find the entrance-steps to this glass-room an excellent "property" for the last scene of that drama, if he could borrow them for the occasion.

Just beyond this spot we came upon a pannier-accoutered donkey laden with tent, camera, and materials that told of an amateur's arrangements for this hilly district. A few miles farther on our road and we met a hack cab with its windows closely blinded with yellow calico, that clearly indicated to what scientific purposes such a vehicle might be turned at last, till even that pariah, "cabby," might become the pioneer to science and art; and so at every turn of the road, and in many an unexpected leafy nook were there signs of the photographer being abroad, till the very threshold of mighty London was passed, and then photography was indeed everywhere rampant, from the door posts to the house tops, till one was disposed to paraphrase the *Lay of the Antient Mariner*—

> Photos, Photos everywhere,
> But never a one to keep.

One is almost led to believe that pathological investigations have of late occupied attention in photography; for you are doubtless aware that *the measles*, as affecting paper prints, has been carefully diagnosed by a professor of photography—that glass positives are frequently subject to attacks of *squamosis*—and that *elephantiasis* (an affection hitherto considered to be almost entirely confined to the inhabitants of tropical climates) is evidently becoming distressingly prevalent in this country, if one is to judge of the portraits that frequently come under notice; but whether the enlargement of the lower extremities of the patients (sitters) is due to constitutional or photographic disturbance of the human system is a matter perhaps open to question. But need one be surprised at these heliographic ailments when even Sol himself is suffering greatly this season from a scorbutic affection vaguely described as "dark spots?"

As we gradually stole upon the murky atmosphere of the great city I was reminded of the peculiar way in which the din of its streets and the resonance of the throbbing life within it impresses itself upon the sense of hearing after a long sojourn in the quiet country—a sensation to which I had been a stranger for many a year, now that, in these railway days, instead of imperceptibly creeping upon London, we rush into its very heart with the clatter of iron wheels and the shriek of steam whistles emulous of rivaling the turmoil of the metropolis itself. The day after my arrival I bent my steps towards "the Land of the West," that being the first district I intended making a foray on for *novelties photographic*. The result of my inquiries at the various establishments I will report to you in subsequent communications. In the meantime,

I remain, dear Thompson,
Yours photographically,
SIMEON HEADSMAN.

COLOURED DAGUERREOTYPE PLATES.—M. Touissant, of Rouen, has announced that he succeeds in fixing the colours of images on daguerreotype plates. He does not give the formula, because he cannot at present specify the precise quantities of the substances employed. The process consists in pouring a mixture of lucine and alloxane upon well polished plates.

Meetings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday, the 4th inst., at the Literary and Philosophical Society's Rooms, 36, George Street,—Joseph Sidebotham, Esq., presiding.

Mr. John Persehouse and Mr. John Mason were elected members of the Society.

The CHAIRMAN called the attention of the members to the fact that the British Association for the Advancement of Science had resolved to accept the invitation from Manchester, and to hold their meeting for 1861 there; and as there would most likely be an exhibition of photographs, it would be well for members to be making preparations, so that a good show might be made on that occasion. He also said that he had lately been over to Paris, but had not seen anything at all new in the photographic way. Most of the photographers there worked with the clumsy old-fashioned walnut-wood cameras. This was to be attributed to the circumstance that there are scarcely any amateur photographers on the continent.

A MEMBER asked whether it was true that the arrangement of the pictures in the Salford Exhibition had been considerably altered by a member of the Society, without the sanction of the committee.

The CHAIRMAN said that it was commonly reported that Mr. J. L. Davies had made the alteration; and, although it was an unpleasant matter, still he considered it should not be passed over, and that it was due to Mr. Davies, as well as to the Society, thus to notice it, in order that Mr. Davies might have an opportunity of contradicting the report, if untrue.

Mr. W. T. MABLEY explained that the entire management and arrangements of the exhibition had been left to a committee of members. One of the rules was, that no pictures could be admitted unless they were sent through the committee. Mr. Davies had not complied with this rule, and, consequently, his pictures ought not to have been admitted at all, though nevertheless they had been admitted. One part of the room was much better lighted than the rest, and the committee had acted as they believed very fairly in hanging one or two of the best pictures of each exhibitor in this place: these pictures had since been taken down by some one, and Mr. Davies's pictures hung in their place. Who had removed them he did not know; but it was not with the sanction of the committee, who felt much aggrieved and insulted that their work should be undone and interfered with.

Mr. J. PARRY moved the following resolution:—"That the Honorary Secretary be requested to write to Mr. Plant, at the exhibition, expressing surprise that he should have allowed any one to alter the arrangements of the photographs without communicating with the committee; and also to Mr. Davies, asking for an explanation from him of his conduct."

This resolution was seconded by Mr. Heywood, and carried unanimously.

Mr. MABLEY further stated that it was a matter of very little importance where the pictures were hung, as the light was very good throughout the room; but such interference as had taken place was a most unwarrantable liberty, and an insult to the society. Several of the members expressed their strong disapprobation of the alleged conduct of Mr. Davies.

After a general discussion on various matters the meeting concluded at an early hour, the thanks of the meeting being first given to Mr. Sidebotham for presiding.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER VII. *(Continued.)*

BACKGROUNDS.

IF you desire any objects introduced behind the figure they must, as I have before said, be very simple and unattractive in their character and few in number; their details, too, must rather be slightly indicated than closely imitated. (See maxims.) Study must also be devoted to the background as associated with the character of your subject: for instance—

Here is, say, a picture of a graceful girl, with the light gauzy drapery of summer fashion floating in swelling, tremulous clouds of transparent material over her—hem!—her crinoline. It is the production of an *artist* photographer, and he could not conscientiously represent anything so fairy-like with strong lights and powerful shadows; so, with true artistic feeling, he has secured

the most tender and delicate gradations he could obtain by a skilful arrangement of his blinds and reflecting screens, without endangering the existence of that roundness and relief necessary to avoid flatness. Now, if you put behind this poetically-treated production a strong dark background, all this beauty, all this poetry, becomes transformed into flatness, harshness of contrast, and a poor, weak, washed out, ineffective result, as unpleasing to the educated as to the uneducated eye.

Or, again, say the picture is one as artistic, of a fine intellectual male head, starting from the surface with its bright high lights and strongly-marked vigorous shadows. Place behind this a pale, delicately-rendered background, and it immediately becomes a sooty and offensive affair, which few would even tolerate and none admire.* (See maxims.)

Another warning I must also give is against introducing lights or shadows in unnatural proportions or positions, for the sake of some conventional or even otherwise legitimate effect. Shadows cannot always be soft and tender, or strong and deep: faint lights and faint shadows cannot exist together. Where the lights are broad and strong the shades must necessarily be faint, and with feeble lights the shadows must be proportionately strong.† The character of the light and shade of your object, then, should regulate that of your background, if you desire your picture to be truthful, as all real art should be. There is a kind of background frequently seen in coloured photographs which was introduced, I believe, by some of our French and German colourists, which is thus obtained:—

A cool, but not cold, grey, bodied with white, is thinly washed over the whole‡, upon this, when dry, the interior of a room, or a garden, or other out-door scene, is faintly indicated by a few smart dexterous touches of light and shade of a similar character; a thin glaze of colour—just the merest indication of colour—is then got with a carefully applied wash; and, by way of finish, a little colour of a more positive description is secured by the use of crayons, for which purpose I can recommend nothing better than Mr. Newman's "polycolor crayons," a few spirited touches from which will produce an especially good effect.

It is sometimes desirable to obtain backgrounds which are intended to embody the characteristic associations of your subject. Thus, military men are frequently represented with the plain of a past or coming battle spreading behind them to the horizon, on which the tents of an army are visible, with piled muskets, cannon, or any other relics of, or preparation for, the fight. A sailor loves a background of sea and rock, or the deck of a vessel. An artist or literary man will perhaps prefer something indicating his pursuits or particular studies. The scientific man that which indicates the peculiar branch of science he most affects. Many sitters have particular hobbies which they especially desire to be in some way or other associated with their portraits; and in theatrical character pictures a characteristic background considerably enhances the general effect. Such backgrounds require very judicious treatment and skilful management. Nothing must attract attention from the figure by its undue prominence (see maxims); and spottiness of colour, or of light and shade, should be carefully avoided. All the colours should be broken and subdued. I might add pages of information upon this subject, and describe many methods of securing effects which, according to my own experience, have been very pleasing; but, lest these articles should prove tediously long, I refrain. I shall content myself in quitting backgrounds by adding that these should not be attempted by colourists who have no knowledge of drawing, as by so doing they may merely spoil their more successful results in the face and figure. If you are not a good draughtsman, with due knowledge of the laws governing composition and *chiaroscuro*, you cannot do better than adhere to the plain backgrounds which I have described. Well-executed pictorial backgrounds are very seldom seen, and failures are but too generally of the greatest and ugliest.

* These remarks are, of course, as applicable to taking photographs as colouring them; and I shall be proud and happy if any remarks of this character which I have made or may make should induce some of our photographers to give more attention to the artistic in their studies.

† This should be remembered by such of our composition printers as use several negatives to produce one picture. It is a rule frequently violated in their compositions, in which a variety of conflicting lights and shadows may often be discovered.

‡ All body-colours dry lighter than they appear while wet.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

J. B.—Simply by adding a little oil to your maglip.

Amelia B.—Your chief object being the very praiseworthy one you name, I say, take your labour *now* into the market: your colouring is neither artistic nor what I could conscientiously call good, but it is neat, clean, and rather pretty; and I have seen work with no higher pretensions which has been executed for more than one of the most prominent, royally patronised, and loftily pretentious photographic establishments at the west end. As far as regards yourself, having been made acquainted with your excellent motive, I am glad to know there is a market for your labour; but I much regret that photographers of position should encourage a species of photographic colouring scarcely superior—if at all—to that associated with cheap lithographs and engravings, simply on the ground of its cheapness enlarging their profits. But if your work does not display very great present success, it is very promising; and I would earnestly advise that you should not be content to remain in the ranks of those who, taking up print after print with the mechanical labour of an unthinking hand, wash on a little "flesh colour" here, stipple a little pink there "as per pattern," *ad infinitum.* Look at the show cases of some colourists and you will understand my meaning. Cry "*excelsior!*" and take *nature* for your guide: for though our much-respected editor, Mr. Shadbolt, seems, in the last number of this Journal, to think it my business to add to photographs a charm unpossessed by nature, I certainly *aim* at contributing only to their perfect *truth*, in giving only the colours possessed by nature and not secured by photography.

Chromo.—Your production displays excellent promise. In its present state it is simply *tinted*, and requires finish. The flesh has little more than a wash of colour; it is neatly and cleanly done, however, and I have no doubt of your ultimate success in better things. A photograph from an engraving is a very bad subject to begin upon; especially when the proof is over-printed, but you should have done more to destroy the blackness of the shadows. So far so good, but you must go farther. I do not promise that in going farther you will not "fare worse," but failure is always the parent of success Your other queries will receive a private reply as soon as I have made certain enquiries

A Would-be Colourist.—"Contrast," Ruskin says, "best manifests the character of everything. Rest can only be enjoyed after labour; sound, to be heard clearly, must rise out of silence; light is exhibited by darkness, darkness by light, and so on in all things." Your specimen of colouring is entirely deficient of this important element. Not the smallest basis of cool, not to say cold, colouring does it contain in all its hot and fiery desert of yellows, reds, purples, crimsons, orange: now just sit down to the piano and try how a series of discords *sound*, and you will have some idea how these colours, thus assembled, *look*. Study Chevreul's book, and paint from nature: the one will give you the scientific theory, the other practice will guide you in its application. You evidently work too quickly. Let the touches be soft, faint, and tender, to obtain the effect gradually.

G. R. S.—Mr. Parris (the same who restored the paintings in St. Paul's) is one of our best photographic colourists. Carrick, no less celebrated an artist, is also much esteemed as a photographic painter. The marble medium was invented by the first-named gentleman, and used in repainting Sir James Thornhill's pictures. I have tried and like it. It dries very hard and dead. It is, I believe, a wax vehicle. I cannot answer your last question, but will see if I can procure the information for you from a friend who is very learned in all such matters.

Dabbler.—The ordinary oil colours will give you the same smoothness of surface, but you must regrind them bit by bit as they are used. The specimen is of the right tone and character for colouring, but it is a little over-printed (if for water).

A Painter.—I am grateful for your encouraging remarks. I believe, with Thackeray, that "art is truth, and truth is religion, and its study and practice a daily work of pious duty:" and I therefore feel no little pride or pleasure in advocating its cause, or defending it from misrepresentation. But you are not just to the good friends who are not of our opinion in this matter: a man should be judged by *his aims*, and not the *means* he adopts to secure their end; and, no matter what his vocation may be, if he is worth a brass farthing, he will uphold it in the world's esteem. I have had much experience in their use, all of which will be embodied in future portions of these articles. Good bye! I suspect you could do more for "the cause" than I. Why not do so?

New Books.

Ackland's Hints on Fothergill's Process.

Horne & Thornthwaite, Newgate Street, London.

We believe that this is a new edition of a little pamphlet which we noticed on a former occasion, but, if so, it has been to a considerable extent re-written. Although some of the details of the manipulation recommended are to the experienced photographer needlessly prolix, upon the whole the directions given are based generally upon sound principles, and therefore may be taken by the novice as safe guides toward the acquirement of presentable negatives.

We are of opinion that a little too much mystery is introduced into the discussion of the character of the collodion suitable for the process. We have never found any kind upon which good pictures can be taken with the wet process that cannot, by judicious management, be made available for the dry one based upon Fothergill's method; but we readily admit that it is far easier to do this with some kinds than with others. We are pleased to find that Mr. Ackland progresses with the times, and does not hesitate to amend what was deficient in his earlier treatise. As a sample of the style we extract the

"CONCLUDING HINTS.

"Clean the glass plates carefully with very clean cloths, avoiding especially those used to wipe the hands after coating with albumen.

"Filter the bath solution whenever about to prepare a lot of plates; and, when not in use, keep it in a stoppered bottle, in a dark corner of the operating room, so that the full glare of daylight may at no time fall on it.

"Allow the collodion to set thoroughly before immersion in the nitrate bath, or it may become detached in washing or after fixing; but, as a matter of course, this must not be carried so far that any part may become dry, or the nitrate bath will act unequally on the film.

"Iodised collodion that has become too thick for use by evaporation may be diluted with rectified sulphuric ether; but *methylated* ether must not be used for this purpose.

"After sensitising the collodion film, wash as described, and do not allow water to fall directly on the surface of the plate, or unequal patches will show themselves in developing.

"The dilute albumen that has been employed to coat one plate must be thrown away, and a second quantity taken for the next plate.

"Use two globe plate-holders, one for collodionising the plate, and the second for coating with albumen; but carefully avoid using the one ordinarily employed for the albumen to coat a plate with collodion, as albumen would thus be introduced into the bath solution, which would speedily spoil it for the purpose.

"Handle the coated plate as little as possible, and always wash the hands after coating with albumen, before removing another plate from the bath; indeed, never take up a plate without washing and drying the hands on a clean towel.

"Give a full exposure in the camera, or the resulting negative will be harsh, and produce black and white prints without middle tints.

"Keep the glass used for the developing mixture perfectly clean.

"Take especial care that no gleam of white light falls on the plates during preparation or drying, and when dry, stow away in *light-tight* boxes of mahogany or tin, if not required for immediate use.

"In developing, take especial care that the developing fluid is kept on the move by being repeatedly poured on and off the plate, or mottling will be the result.

"Guard against over-development, as a comparatively weak negative by this process will print well, owing to the nature of the deposit forming the shades having a greater action, in stopping the light whilst printing, than that produced by the ordinary collodion process.

"I have thus given what I hope will prove a clear description of this beautiful process, and as success with it follows only from paying attention to *minute* particulars, I would ask those who are led to make a trial of it from my description, to *strictly* follow the plan I have laid down, as a slight alteration of manipulation frequently gives rise to vexatious failures. Should any difficulty arise, I shall be happy to answer any queries by post; but it would much facilitate my doing so if such queries were written on paper, distinct from the letter which accompanies it, leaving sufficient space between each query for my reply."

From the same pamphlet we also give the following, as useful to some of our readers:—

"BATH TESTER.

"In working with either the wet or dry collodion process, and in printing paper positives, it is absolutely essential that the bath solution should be preserved as near as possible to its original strength; and if it falls much below this strength, nitrate of silver must be added to supply the deficiency.

"Many instruments have been devised for this purpose, but the form shown by Fig 1 is the most simple in action, and sufficiently exact for the purpose. To use it we must proceed as follows:—

"Take of highly dried and perfectly pure chloride of sodium 84¼ grains, and dissolve it in 20 ounces of distilled water. This forms the test solution, and requires to be made with exactness, or the result obtained by its use will be erroneous. A second solution is also needed; this is made by dissolving twenty grains of bichromate of potash in one ounce of water.

"To test the strength of a bath solution, take the bath tester, Fig 1, and drop into it ONE DROP *only* of bichromate of potash solution, then fill the tube up to the lowest division, marked 0, with the bath solution, and add the standard test solution gradually, shaking at frequent intervals; when the colour of the precipitate, which was at first brick red, changes to a lighter tint, add the test solution more gradually, and continue to shake up between each addition. Continue to add the test solution drop by drop until the red tint of the precipitate suddenly changes to white, showing that all the nitrate of silver is decomposed, and that enough test solution has been added. Now read off the division on the level with the surface of the fluid in the bath tester, and it will be equal to the number of grains of nitrate of silver contained in each ounce of the bath solution. Thus, supposing, after having performed the experiment, the fluid in the bath tester stood level with the 39th division (counting from below upwards, the same as the tube is figured), this would indicate that each ounce of the bath solution tested contained 39 grains of nitrate of silver.

"This plan of using bichromate of potash to show by a change of colour when all the nitrate of silver is converted into chloride was published some years since in the *Journal of the Photographic Society*, and although but little used, answers perfectly in all cases except to test the aceto-nitrate of silver bath, after having been used to excite collodio-albumen plates. In this case, the precipitate which forms on adding the test solution remains coloured, however much is added; therefore, the use of the bichromate of potash solution must here be dispensed with, and the test solution added gradually, shaking after each addition, and allowing the white chloride of silver which is formed to settle down, until the test solution ceases to produce any more cloudiness in the clear portion of the contents. The division level with the surface of the fluid in the bath-tester here also indicates the number of grains of nitrate of silver per ounce."

FIG. 1.

Foreign Correspondence.

Paris, July 10, 1860.

THERE is much talk here at present of a new and important application of photography, which has just received an official consecration from the Academy of Sciences, in a report by Mons. Laugier, one of the most distinguished members of that celebrated society: I speak of the employment of photography for surveying and for reconnoitering. Recently, Mons. Laussédat, Captain of Engineers, presented to the Academy a long and interesting paper on the subject, containing quite a system which the author had himself practised, and the advantages of which he had proved. I do not intend to repeat here a description of that system, but I will call your attention to Mons. Laugier's report, giving a *resumé* of it, which is published in the *Lumière* of this week. It is true that photographic processes were already used for the reproduction and reduction of maps and topographic plans. While at Brussels, in 1856, I saw an *atelier* which was installed at the War Ministry for this special purpose, under the direction of Mons. Libois, a staff-officer, and a very able operator. At the same period, Mons. Riffaut was entrusted by the French administration with the transferring of copies of a similar nature upon steel by means of heliographic engraving. At various times Russian and Sardinian officers have been sent to Mons. Nièpce de Saint Victor, to study his processes; and we learn from the recent publication of Colonel James's process that such labours continue to occupy attention in England. But it is not merely as a supplement to the means already employed by the surveyor that Mons. Laussédat proposes photography—it is to the original production of plans that he applies it. He thus opens a wide and, as yet, unexplored field to our art, and renders to science a large service.

Another general theme of conversation at Paris is the diminution of the sun's light. You know with what impatience we Parisian folks await each year the sunny days. The month of March has scarce gone by when we complain that the temperature is still wanting in vernal suavity—that the heavens are not yet wholly azure—that the trees hasten not to clothe themselves with blossoms. Spring-tide is the sovereign cure of all our ills. The sun is our chief comforter. He it is who makes us see all things in rosy hues; and, were we in philosophic mood, to study the influence which he exerts upon our destinies, we should arrive at unlooked-for conclusions. On a rainy day the Frenchman, and above all, the Parisian, loses fifty per cent. of his real value. Judge, then, of the state we must be in this year, when spring has failed us, and when summer lets the Julian month pass by, and deigns, so to speak, no token of its presence. We began by grumbling, and then we grew to be uneasy: we asked what might be the cause of the season's protracted inclemency. We were told that the sun's spots had taken considerable development, and that they changed their aspect at every instant. Now, if the dark portion of the sun's disc had grown, the luminous portion had become so much the less; hence there resulted for us diminution of light and concurrent diminution of caloric. Such is the reasoning put forward to account for the unusually inclement season. To confirm this theory, however, it should be ascertained whether the so-called lowering of the temperature has taken place throughout the globe; for, if the sun has really lost a portion of its heat and power, it will be felt more or less everywhere. The fact, interesting for everyone, is especially so for photographers; and their observations might perhaps aid science in the re-solution of the problem. I have, indeed, for some time past, heard not a few of our artists complain of accidents in their operations—of want of success to them inexplicable; but such things often happen, and cannot, without positive experiments, be attributed to the phenomenon we are speaking of. Besides, I do not know that the time of exposure has in general to be prolonged, which would be the case if the sun had in reality lost in intensity. Our friend and *collaborateur*, Mons. A. Gaudin, says that the decrease of the solar light is in the proportion of one per cent. He proposes that photographers in various countries should make experiments in this direction, and that they should take the solar image at various hours of the day. Pictures of this kind, carefully made, would be valuable documents for scientific men. Mr. Warren De la Rue, who has already successfully applied photography to astronomical observations, might supply useful instructions for such experiments.

While I am speaking of the diminution of the solar light, let me mention the incredible increase in the number of itinerant photographers. They are now a-days become a very plague, somewhat like the swarms of locusts which fell in ancient times upon the land of Egypt. Probably you in England know not this modern tribe getting their living with the big drum and the objective, and holding a place midway between the artist and the mountebank. If so, I congratulate you on such exemption. The first that was seen appeared two or three years since at a suburban *fête*, with a daughter of Anak on one hand and a child with two heads on the other. He appears to have made money, for he very soon had imitators. First it was an enterprise conducted by one man, who had representatives and branch establishments at all the fairs in the environs of Paris. Now the tribe, grown and multiplied, has invaded the capital. Its members set up their dwellings along the Boulevards which surround Paris, and which, before the extension of the city at the commencement of this year, formed its boundaries. A few planks covered with an awning compose the establishment. At times a coffee or a beer shop is attached to the operating-room. The wife supplies the customers with drink, and entertains them with a *select* conversation, while the husband is occupied with the manipulations. In the interior, every piece of waste ground arising from the demolitions which are rendered necessary by the opening of new Boulevards, every house in course of construction, is seized upon by these nomadic artists. On the Boulevard de Sébastopol, one of the largest and finest streets recently opened, from twenty to thirty at least may be counted. They put up sign-boards illustrated with fantastic symbols, and distinguished by their barbarous style. They call themselves the

"collaborators of the sun," and inscribe over their doors, "*Au génie de la photographie*,"—"*Aux merveilles du nouvel art*,"—"*Aux fils de Daguerre*,"—&c. Some of the directors of these establishments think themselves bound to let their hair grow, and to assume a *characteristic* costume to represent their art more worthily. There is one who is dressed as an Arkansas trapper, to resemble as much as possible the hero of a popular novel. Generally in these galleries they execute positives upon glass, or transferred to waxed cloth. The portraits are announced as costing one franc; but it is rare for the unwary passer who enters to come away for less than five or six francs, for he yields nearly always to the charms of a picture of larger dimensions, or with an ornamented frame. I have seen some of these portraits: now and then they are tolerable, but woe to those whose hair is blond!—they are sure to have a portrait of the darkest hue.

May the fates preserve you from strolling photographers!

ERNEST LACAN.

TO OUR READERS.

To meet the additional expense incurred for carriage and postage of this Journal throughout the Provinces, arising from the great bulk it has now assumed through the increased amount of matter published in each number, our Provincial Agents will be compelled to charge this and all future numbers at 4d. each. The price to purchasers in London and Liverpool will remain the same as at present, namely, 3d.; and subscribers can still have it forwarded direct from the publisher as heretofore upon payment of 8s. per annum IN ADVANCE.

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

ERRATUM.—*In a portion of our present impression a printer's error occurs. In the first of Mr. Wall's "Answers to Correspondents," page 211, "maglip" should be "magilp."—The mistake occurred through a "transposition" of the line.*

FADED GLASS POSITIVES, &c.

To the EDITOR.

SIR,—I beg to thank you for your satisfactory solution of my several queries contained in the last issue of your much-valued serial. By this evening's post I purpose forwarding you one of the unfortunate yellowed proofs mentioned in my last epistle, being lucky in having kept a supernumerary one as a remembrance of its respected original (in her eighty-ninth year), which I have returned, quite perfect, in place of the one about to be sent you. You will thus be enabled to form a better opinion of the correctness or otherwise of your surmise respecting the cause of the change of colour that has taken place. The following addition to my former statement may tend to assist your further judgment of the matter:—Some time since, finding myself unexpectedly minus nitrate of silver, I purchased a small quantity at a neighbouring town, and, not having a phial with me, brought it home in paper. Through forgetfulness it thus remained for a fortnight or longer, when on opening the packet a portion of the salt had become discoloured and useless for ordinary purposes. I suppose it had deliquesed, and become contaminated with a part of the organic matter or impurities of the material containing the nitrate. Fancying that the solution of cyanide of potassium increased the whiteness and silvery tone of the picture in direct proportion as it was well charged with silver, I have been in the habit of occasionally adding to it from my exciting bath stock bottle a portion of its contents; and I may have been more liberal of this expensive chemical of late, foolishly thinking thus to economise my partially decomposed and otherwise useless silver salt, by using it in place of the bath solution as heretofore. The only way that I can account for the other three proofs taken at the same time, and fixed and varnished with the same chemicals, not having shared the same fate as the one now about to be sent you is, that my cyanide bottle may have been short of solution at the time, and I may have refilled it after taking off the first proof from my cyanide stock bottle, which is without silver, and always stands ready at hand.

Allow me to correct a doubt, raised in my last letter, respecting the propriety of using albumen on glass positives, in consequence of the phosphorous and sulphur I had supposed it to contain. I now find albumen to be a very simple fluid, consisting principally of carbon, its other constituents being three harmless gases, the phosphorous and sulphur of the egg being entirely confined to the yolk.

A short time since the proprietors of copyright of engravings and prints appeared determined, by advertisement, to suppress the sale of photographic copies taken from their works. To my surprise I see these copies offered for sale as plentifully and generally as before. Taking it for granted that the parties thus exposing them in their shop windows cannot (all of them at least) have obtained leave from owners of copyrights for so doing, will you kindly tell me whether the restriction holds good with all engravings, or whether it be confined to a certain few—it may be registered ones? If the former, whether the prohibition applies also to amateurs who may be inclined to copy a certain print or prints for gratuitous distribution among their friends?

Having made the above inquiry among my photographic acquaintances, as well as from gentlemen skilled in the law, not leaving unasked the shopkeepers themselves, and without obtaining the information sought for, I am led to believe that such particulars are not commonly known,—may I trespass still further on your usual readiness to oblige by requesting your opinion on the abovenamed points?

To induce others better acquainted with the alabastrine process than myself to make known the results of their experience, I would state that I have recently become possessed of a proof, whitened by bichloride of mercury more than six years since, which still retains its original purity and brightness. As a further test of the permanency of alabastrine pictures, the one in question, during two-thirds of the six years, has been thrown aside in a dark lumber-room, and at the same time exposed to the deleterious exhalations and gases of the crowded town of Plymouth. The spare solubility of bichloride of mercury in water renders it difficult of being washed out of the whitened proof, more especially its last remaining traces, which have sunk deep into and saturated the collodion film. Could there be any objection to flooding the picture with dilute hydrochloric acid, in which fluid the bichloride is instantly soluble, prior to its final washing? Calomel, of which the whitened surface of the alabastrine picture is principally composed, is not soluble in hydrochloric acid, consequently the brightness of the proof could not be injured by its use.

I certainly feel great reluctance in thus troubling you, and more especially in occupying space in your very practical periodical which would otherwise have been filled with more useful matter, still from the pleasure and frequent profit I have derived from the perusal of your answers to various correspondents, I have been induced to do so in the hopes that others may be led to record their failures and their difficulties, which frequently result in the exposition of useful facts that might otherwise have remained known to only a few. Wishing you success in all your undertakings,—I am, yours, &c., HENRY H. HELE.

July 3rd, 1860.

[We are more than ever convinced of the correctness of our surmise relative to the cause of your glass positive having become faded since inspecting it and reading the preceding letter. We regard the addition of a silver salt, in any considerable quantity, to the cyanide solution as a decided mistake. Weaken the energy of your fixing bath, if too great, by dilution with water.

We are not disposed to acquiesce in the correctness of your present opinion relative to the harmless nature of albumen, or rather the white of an egg, which, though consisting principally of albumen, contains besides an alkali, small quantities of chloride of sodium, sulphate and phosphate of soda, phosphate of lime, &c., quite sufficient to interfere with the stability of the reduced silver on the film.

It is possible that the photographs to which you allude may have been taken from prints the copyright of which has expired. We should scarcely think of replying to a purely legal question, but we believe that there exists considerable uncertainty as to the actual state of the law upon the point raised.

We have had no personal experience on alabastrine positives, if by that term you intend anything beyond positives whitened by solution of bichloride of mercury in dilute hydrochloric acid, as originally introduced by Archer. Possibly our correspondent, Mr. G. W. Simpson, may be inclined to favour you with some hints on the subject.—ED.]

THE FOTHERGILL PROCESS.

To the EDITOR.

SIR,—As some of your readers may be operating with the Fothergill process, and fancy they are working it with a short exposure (some say short if it be only three and a half or four minutes), I may just mention that I am now giving from fifteen to twenty-five seconds exposure, with a double achromatic quarter plate lens, and five-eighth inch stop. I should like to know if any one else is succeeding with the same exposure?

Enclosed are specimens. One is a view in Healey Thnitch, near Rochdale, a wild, romantic spot, and worth the visit of photographers, as there might be half-a-dozen good views obtained. The exposure for this was twenty seconds, at eleven o'clock a.m., April 7th, 1860.

The next is *Lover's Walk, Littleborough;* a nice bit of scenery. Exposure fifteen seconds, April 14th, 1860.

Lastly, a view of an old baronial hall, *Pike House, near Littleborough.* Exposure, twenty-five seconds, April 24th, 1860.—I am, yours, &c.,

A. WHITHAM.

[The prints are somewhat grey and flat in colour; but it is evident that the negatives are capable of yielding much better proofs, the exposure having been quite sufficient to impress the detail of the shadows. With so large an aperture as five-eighths of an inch the exposure of twenty seconds is equal to that of two minutes with a quarter-inch stop, or *eight minutes* with one of one-eighth of an inch—a size not at all uncommon with stereoscopic lenses for taking landscapes, as where much "distance" is included the effect produced is far richer than in those before us.—ED.]

PORTRAITS IN SITTING ROOMS.

To the Editor.

Sir,—Having been a reader of your Journal for some months, and finding it contain milk for the babes of the black art as well as strong meat for the men, I am induced, as one of the former, to trouble you with the following questions:—

1. Wishing to take portraits in a room lighted with one window facing east, how must I place my sitter?

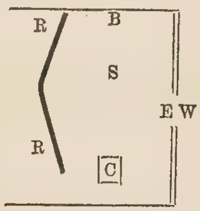
2. What background is most suitable for alabastrine pictures?

3. Should the formula for re-developing solution for alabastrines contain iron,—and how much?

4. Are kaolin and China clay the same.—I am, yours, &c.,

A BABE AND SUCKLING.

[1. Place the sitter with one *side* next to the window, and illuminate the other side by means of a pair of white screens, folding after the manner of a clothes horse, and place the camera opposite the sitter thus—



E W, east window; S, sitter; B, background; R R, reflectors; C, camera.

Lay a white sheet or drugget on the floor in front of the sitter, and a piece of white calico in an inclined oblique position over the sitter, so as to reflect light upon the top of the head.

2. A shade of grey, just dark enough to contrast with, and throw up the face, or a brown paper colour is very good when a contrast with very light dresses is desirable.

3. The formula for the so-called "re-developing solution" is a trade secret. If any iron salt enters into its composition it probably is the perchloride in small quantity.

Mr. Archer's formula for *whitening* positives is:—

Perchloride of mercury	2	drachms.
Hydrochloric acid	2	"
Water	6	"

One part of the above solution to ten parts of water may be used for re-developing.

4. Kaolin is the same as China clay, but the Chinese mineral, *petuntze*, (peh-tun-tsz), is sometimes called China clay in error.—Ed.]

M. PESCHARD'S PROCESS.

To the Editor.

Sir,—Every now and then the photographic world is startled with the surprising announcement of *a* new *dry process*, which generally turns out to be no more new than photography itself.

In your last number appeared one of these announcements, by M. Peschard; and what in the name of all that's photographic there is new in this process I cannot conceive. About twelve months ago I was experimenting in the direction indicated, and I think tried most of the gums and resins soluble in ether, which were added to the collodion in a similar manner as that described by M. Peschard. The result of these experiments I published in the pages of a contemporary.

Not that I wish to claim the discovery of this process, as I believe Mr. Hardwich gives a description of one somewhat similar; nor do I doubt that the present discoverer has published this process in ignorance of its having appeared before.

The results, however, are far from being as satisfactory as I was first led to suppose; the plates rarely developing free from stains, owing, I think, to a partial decomposition of the nitrate of silver remaining in the pores of the film.

There are two other great drawbacks to this process:—first, the plates will not keep over a few days; and, secondly, one half the plate is generally more sensitive than the other, owing to accumulation of the nitrate of silver at the lower end of the plate in draining.

With regard to the sensitiveness of these plates, I may mention that I have taken views in five seconds; this is the only quality which can recommend them at present. But still I would say, "*nil desperandum.*" Why may not something be found to add to the collodion instead of applying preservatives afterwards?—I am, yours, &c.,

Shooter's Hill, 3*rd July*, 1860. THOMAS CLARK.

[The communication of M. Peschard is one that has been in type some time, and came through one of our *collaborateurs*. The only novelty in it consisted in the combination of rosin with Peruvian balsam, the former ingredient having been employed by M. l'Abbé Despratz and others. We have but little faith in the principle involved of adding a so-called preservative agent to the collodion itself, and have never yet seen a picture produced by following it that has been entirely free from defects, and those of a serious nature. It is *possible* that by adding some adhesive resin to keep the film on the glass something useful might accrue, but it should be one *inactive* as a photographic agent.—Ed.]

TONING.

To the Editor.

Sir,—The following is the result of some experiments recently made with an alkaline gold toning bath, which, if of sufficient interest, you are at liberty to publish:—

TONING BATH.

Water	20	ounces.
Hyposulphite of soda	5	"
Carbonate of soda	20	grains.
Chloride of gold	10	"

The first dozen toned in this bath in 15 minutes, the second 20, the third 25, and the fourth 30.

I then added five grains of chloride gold to revive it, when the first dozen toned in 20 minutes, the second in 30, the third in 45, and the fourth in 70,—the proofs declining in vigour in proportion to the length of time taken in toning.

It would appear from these experiments that the above bath is capable of toning about fifty stereographs without further addition of chloride of gold, and if it is desired to tone any more in the same bath (a plan not to be recommended) gold must be added in proportion to the number of prints—thus, if two dozen are to be toned, add five grains of chloride of gold, if four dozen, ten grains, and so on.—I am, yours, &c.,

THOMAS CLARK.

[It has many times been remarked that it is as useful to record failures as successful operations; but we may now add that it is useful to record *misapprehensions*, for we certainly never should have imagined, without the evidence before us, that any one could have supposed the formula above given to be what is known as "the alkaline *gold* toning bath." We know of but one kind of toning bath likely to be more injurious in its operation than the preceding, that is one in which the few grains of carbonate of soda are omitted; but we do not hesitate to condemn this one in very strong terms, for faded proofs must ultimately be the result of its use.—Ed.]

ANSWERS TO CORRESPONDENTS.

Querist.—Already replied to.

J. Cranmer.—Not likely; but you can try.

A. B. C.—There is no royal road to photography. You must feel your way gradually.

Well-wisher is thanked for his note and the compliments it contains.

J. H. W.—Makers—No. 1 best, then No. 4; after these, 5, 8, 12. Dealers—13, 16, 18.

S. A. G.—We think you will find the Fothergill process best suited for your requirements.

J. H. L.—The matter of your letter we should be happy to publish, but the style is inappropriate.

P. Jones.—We have forwarded your note, but cannot promise that you will receive any reply *direct*.

A Lad in Trouble.—You have simply omitted to *fix* your proof—use a solution of hyposulphite of soda.

R. Hulett.—Nos. 5 and 1 equal and *far* above the others. No. 3 comes next in excellence; then 8, 6, and 2.

Eric.—We believe that it is to be procured; in fact, we have no doubt of it. Address simply "Wolverhampton," and it will reach him.

T. W. C.—The diffused light of the fire does not affect the plates; but we gave all the information contained in the pamphlet.

John Howard.—Exhibition not yet fixed—most probably at Manchester, about this time next year. For developer, dissolve by heat in one ounce distilled water 320 grains protosulphate of iron; also in the same way 300 grains of nitrate of barytes in three ounces of distilled water; mix while hot; a white precipitate will be formed, which filter away, and keep the liquid in a closely corked bottle quite full. This requires *no* addition of acetic or other acid, but will not "keep" long.

Maxwell.—Albumenised paper to be depended upon is very difficult to procure just now, as we hear from very many professional photographers. We have reason to believe that, as a rule, the fault lies with the *paper*, and not with the albumen, though doubtless the latter is sometimes the culprit. If you can prepare your own, we recommend you to *try* Hollingsworth's paper: we do not know that it will answer your purpose, but we have reason to think it will.

Dirty Fingers.—It is possible that, by coating them with india-rubber solution (procurable at the mackintosh shops), you might make them do; but what we recommend to you are simply some india-rubber *finger-stalls* (cost about threepence each), reaching to about the middle joint of the fingers. We find that, with one on the thumb and one on each of the two next fingers of the *left* hand, we rarely make a mess of our own; but there is no difficulty in performing most of the operations with all the fingers on both hands protected.

S. L. (or F. L.)—We fear that the paper is quite deficient in chloride; you may possibly make it work by floating it for several minutes, say five, upon a solution of chloride of ammonium, twenty grains to the ounce of water, and drying it previously to sensitising in the usual way. The paper is not good, and we perceive that the whole of the size has been removed.

You may print glass stereographs upon plain or ground plates as you please—the former is the simpler plan, and you may view them with a sheet of white paper under them, or a piece of ground glass in the stereoscope. Some operators produce the effect of ground-glass by means of a varnish.

M. C. C.—1. We have rendered available several defective pneumatic plate-holders by attaching to the faulty surface moderately thick sheet india-rubber, by means of the ordinary india-rubber solution. It requires, however, ten days or a fortnight to be allowed to ensure the proper amount of adhesion. We found some little difficulty in procuring a small piece of sheet india-rubber, so made use of one of the common india-rubber (*not* vulcanised) tobacco pouches—cost one shilling.

2. The pyroxyline is doubtless decomposed, and the film powdery, hence your annoyance. Add some collodion of a tenacious quality, freshly made, and you may overcome it. Allowing the film to dry too much before immersion in the sensitising bath sometimes gives rise to the inconvenience named.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 123, Vol. VII.—AUGUST 1, 1860.

We find in the pages of a German contemporary an article by P. Liesegang, on Positive Printing, which contains some useful suggestions, and which we should have been inclined to have reproduced in full, but for the fact that an *impromptu sel d'or* toning bath is recommended, a movement which we regard as retrograde. We propose, however, to indicate the *modus operandi* advocated as being worthy of attention. It is as follows:—

To produce a fine, clear, and vigorous proof, with bright lights, purple shadows, and rosy half tints, the chief points requisite are: 1st. Paper with a hard smooth surface, upon which the picture may lie without sinking into the substance. 2nd. The presence of acid in the sensitising bath to secure clearness and brilliancy. 3rd. That no more silver salt be contained in the paper than is sufficient to secure a good print. 4th. The employment of the proper light for printing, sunlight only being used for very powerful negatives. 5th. The greatest cleanliness in all the vessels and solutions used. 6th. The sensitising and toning to be performed in the dark. For the preparation of the paper, instead of albumen, arrowroot is recommended, upon which it is asserted that proofs can be obtained equalling those upon albumen in delicacy, but without the objectionable gloss. German paper is preferred (naturally); each sheet is to be fastened, smooth side upwards, upon a flat board, and with a clean damp sponge a thin coating of the arrowroot mixture is to be laid on with a very light touch, so as not to roughen the surface of the paper; the slight lines left by the first sponge to be effaced by a few delicate touches with a second sponge, damp and scrupulously clean.

The arrowroot mixture is composed thus:—In five ounces of distilled water dissolve one hundred grains of chloride of sodium, and one grain of citric acid; filter into a clean vessel, and add eighty grains of pure arrowroot; heat the whole until it boils, stirring all the time with a glass rod; and allow it to cool. Before using the paste thus prepared remove the film formed on the surface when cooling. The sensitising bath consists of sixty grains of nitrate of silver to each ounce of water, with the addition of one drop of nitric acid. For papers sensitised upon this bath a toning bath of *sel d'or* of a strength of about half a grain to each ounce of water is directed; but, for papers sensitised upon a bath of ammonio-nitrate of silver (eighty grains to the ounce), a toning bath analogous to one suggested by Mr. Burnett in a former number of this Journal is to be employed. The toning bath is thus made:—Dissolve 60 grains of hyposulphite of soda in one ounce of distilled water; pour half of the solution into another vessel, and add to it half a grain of double chloride of platinum and sodium; then dissolve ten grains of nitrate of silver in one drachm of water, and add one drop of hydrochloric acid; a white precipitate is formed, which is left to be darkened in the light—this is to be dissolved in the other half of the hyposulphite of soda solution; mix the two portions and allow them to stand for some hours until a grey precipitate has fallen. This bath produces a fine brown tone.

The principal novelty in the preceding is the use of arrowroot as a vehicle for the sensitive chemicals, the paper being merely intended to act as a support. The principle involved is therefore identical with that advocated by us in a paper read before the Photographic Society between three and four years back, entitled, *Observations on Positive Printing*, and which will, on reference to the *Journal of the Photographic Society* for the period specified, be found recorded. Since that time we have found no reason to change the opinion then expressed upon this point, that the great desideratum is to keep the image as much as possible on the surface of the paper; and we therefore cordially coincide with the views held by our German *confrère*. The material of which we availed ourself for the purpose was gum tragacanth: it is by no means improbable that arrowroot may be preferable, and it is certainly easier to prepare properly. The use of a slightly acid sensitising bath is well known to assist in keeping the lights pure upon albumenised paper: analogy would therefore lead us to suppose that the same may apply to arrowroot; and, if memory do not play us a trick, Mr. Mabley found that it was advantageous to employ a small quantity of free acid in the nitrate bath, as it facilitates the subsequent operation of toning.

That no more free nitrate of silver than is quite sufficient for the purpose should be used is a proposition that recommends itself, both on the score of economy and to prevent the image being formed in the fabric of the paper; and the instruction to perform the operation of toning in the dark room is one that we consider deserving the utmost attention. We have no doubt whatever that many a spoilt proof is due to its exposure during this part of the process to ordinary daylight; indeed, we have not unfrequently seen two prints in one toning bath turn out one good and the other useless, in consequence of the under one having been protected from the light by the upper one, which was exposed to it. We are glad to find our own views so completely corroborated by an independent observer.

It is gratifying to record that the expedition to Spain, under the leadership of the Astronomer Royal, for the purpose of observing the eclipse of the sun, which occurred on the 18th ultimo, has proved eminently successful, especially as regards the photographic department; for a telegraphic message in the following words was published in London on the 19th:—"The success was complete: we have two photographs of the red flames, which prove that they belong to the sun, and many photographs of other phases." The camera is thus turned into an astronomical assistant, who does not let fancy run away with him or imagination play fantastic tricks, and one that is also free from any "personal equation." We have learnt that dry plates of various kinds—viz., Taupenot's, Fothergill's, metagelatine, and Dr. Hill Norris's, were taken out, as also some sensitised chloride paper, in one of Marion's preservative cases. It is highly interesting to note how, step by step, photography is pressed into the service of almost every branch of science, commencing generally with an amusing experiment, and ending by becoming an indispensable adjunct.

On perusing M. Claudet's paper *On the Principles of the Solar Camera*, recently read before the Members of the British Association for the Advancement of Science, we should certainly have been tempted to conclude that this celebrated photographer had never looked through a well-constructed microscope, had we not had ocular demonstration of the contrary. We fear, however, that on these occasions he had eyes which saw not, or at any rate did not heed, otherwise he could not possibly have failed to have been struck with the fact that "the principle" which he says "has not yet been explained even by the inventor himself in the specification of his patent," is precisely that which is acted upon in using with the achromatic microscope an ordinary Woollaston's condenser attached to the sub-stage; and that what M. Claudet proposes as an improvement in the solar camera, is simply the adoption of the improvement long since effected in the ordinary Woollaston's condenser by rendering it achromatic. We have before now asserted that for enlarging photographic negatives nothing more perfect could possibly be devised than that which already exists in a first-class microscope, it being simply a question of the size of the instrument. M. Claudet has come to the same conclusion, though by a different route; but, being unfamiliar with microscopical manipulation, he is not aware that, when examining any transparent object by the assistance of the achromatic condenser, all the conditions upon which he insists as essential to the perfect performance of the solar camera are rigidly fulfilled. M. Bertsch, on the contrary, is evidently a practised microscopist, as is evidenced by a communication made by him to the French Photographic Society at its last June meeting—a translation of which will be found in another column, and one to a similar effect in a former number—in which this gentleman points out that rays rendered convergent by a simple homogeneous lens are necessarily dispersed, in consequence of the varying refrangibility of the different coloured rays; and the disturbance is still further aggravated by some of the rays falling more obliquely than others upon the glass of the negative, are refracted with greater force, and, traversing a longer distance through it, the separation between the blue and red end of the spectrum becomes so great that it is hopeless to expect to obtain a sharp image with such defective illumination.

To convince anyone of the importance of this objection it is only necessary to show them any ordinary test object under the microscope, such as the *Pleurosigma angulatum*, or one still less severe, the *Pleurosigma hippocampus*—illuminating first by means of the Woollaston, and subsequently by the achromatic, condenser. In the former case the markings appear blurred and indistinct; in the latter sharp and clear, without any alteration of the optical part of the instrument.

We trust that M. Claudet will put himself in communication with M. Bertsch. The former is too good a photographer to be content with anything but the best results; and in his advocacy of the advisability of turning attention to the production of large pictures, *via* small negatives, we cordially concur: it is a point to which we have been for some time past endeavouring to urge our most energetic operators.

The collodio-albumen process has long been a deservedly favourite one: too many, however, are very apt to complain of the tediousness and the uncertainty of the preparation, which they allege deteriorates sadly from the pleasure they feel in the subsequent development. We are informed that experiments in rather a new direction will tend to remove some of the causes which have given rise to these complaints. We believe that probably before our next we shall be in possession of the particulars; and should it occur to our readers meanwhile to elect a favourite, we would recommend them, in election phraseology, to "reserve their pledges" until they have seen the report we have alluded to.

PHOTOGRAPHIC CONTRIBUTIONS TO ART.

In an article which appeared not long since in these pages, from the pen of Mr. Wall, allusion was made to a very beautiful study recently produced by Mr. Rejlander, the subject being *The Head of John the Baptist.* Although we had a copy of this artistic work then in our possession we abstained from more than a casual notice of it, because our attention was then directed more to the question of the legitimacy or illegitimacy of "printing from several negatives" than to the peculiar merits of this one of Mr. Rejlander's compositions, and hitherto the opportunity of again reverting to this production has been wanting. It is, however, at the moment of writing before us, and we have, while noticing with much gratification the satisfactory result obtained, to offer a few remarks *en passant.*

In this composition there are no harsh lines, nor is it possible to detect the junction between the parts of the various negatives employed. There is brilliancy and sharpness of rendering where such qualities are called for both by art and by common sense—as, for instance, in the eyebrows, eyelids, lashes, beard, and other parts upon which the attention of the spectator would naturally be concentrated — yet there are absolutely no "cruel cutting" outlines, which, on the contrary, are all softened and toned down to a most pleasing extent; while the folds of the cloth on which the head lies, and the vacant space above, without being in the slightest degree hazy or indistinct, are charmingly mellowed to a very unobstrusive reality, exhibiting aërial perspective in a pre-eminent extent. There is nothing like spottiness, no "impertinent" high lights, and the shadows are rich and transparent as shadows ought to be.

So much for manipulation: now as regards conception of the subject. In this there is much to commend—there is little, very little to which to object. A hypercritic might say that the features scarcely present the aspect of those of a Jew, though it would be difficult to prove that they were not so. The expression is one of calm placidity, devoid of all suffering, and indicative of a mind at perfect peace, before departure from its earthly tabernacle. The features are noble and intellectual in character, denoting a soul capable of great deeds and strong endurance—one that would regard the executioner with his sword to summon him from this world with as much calmness as if he were the bearer only of a summons to attend in the next room. It is the dignity of martyrdom which rests unsullied on the brow, in spite of the heedless defilement of the fingers of the headsman as he grasped the curls above the forehead to aid him in lifting the head into the vessel, where it now reposes in majestic quietude. It is truly a study for a painter!

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 9.

It will be remembered that, in a paper which we had the honour to read at the April meeting of the Blackheath Photographic Society, there appeared a table of composition of various mixtures of nitrosulphuric acid, of which a reprint is given below:—

COMPOSITION, BY VOLUME, OF NITROSULPHURIC ACID FOR PREPARING PHOTOGRAPHIC PYROXYLINE.

	Oil of Vitriol, 1·845 at 60 F.	Pure Nitric Acid, 1·45 at 60 F.	Water.
No. 1 ...	3 ...	1 ...	$\frac{7}{8}$
No. 2 ...	2 ...	1 ...	$\frac{5}{8}$
No. 3 ...	1 ...	1 ...	$\frac{5}{16}$
No. 4 ...	1 ...	2 ...	$\frac{5}{32}$
No. 5 ...	1 ...	3 ...	0

It was affirmed that each of the five mixtures imparted to immersed cotton nearly the same per centage amount of peroxide of nitrogen, but that nevertheless the properties of the resulting collodions were widely different. Few, perhaps, would have been at the pains of verifying such a table, and it might have remained in the pages of the Journal for a long time unquestioned. Nevertheless, as the theory rests partly upon its correctness, it seemed desirable to place it in the hands of a chemist experienced in the examination of nitrosulphuric acid and of gun cotton. We there-

fore prepared the mixture No. 1 at the top of the scale, and also No. 5 at the bottom, and submitted them to Mr. Hadow, whose researches on this subject are well known. Before giving the results it may be well to mention the course of proceeding which that gentleman adopts in such analyses. The cotton is first dried by enclosing it in a glass tube through which air heated to 212° F. is transmitted: it is then allowed to become cold, and weighed whilst still in the tube, to avoid any absorption of atmospheric moisture. The acid to be examined is placed in a wide-mouthed stoppered bottle, and cooled down to the temperature of the surrounding air; after which the cotton is dropped loosely into it, and air bubbles, if present, are removed. At the expiration of twenty-four hours the pyroxyline is taken out of the acid, and washed upon a filter with distilled water until the washings cease to redden litmus paper; it is then dried, not by hot air as before, but *in vacuo* over sulphuric acid. The exact increase of weight having been ascertained by a delicate balance, there remains still one precaution to be taken. The acid may have acted slightly upon the fibre, and caused a loss from solution; therefore the pyroxyline must be brought back again to the condition of common cotton, and it must be noted whether the weight corresponds to the original weight. This operation is performed by digesting the pyroxyline for a short time in an alcoholic solution of sulphide of potassium, which removes the whole of the peroxide of nitrogen in the form of nitrite of potash, and leaves the fibre of the cotton in its original state.

The numbers obtained by Mr. Hadow, calculated as 100, were as follow:—

In mixture No. 1, 100 grains of cotton became 169·2 grains.
" " No. 5, 100 " " " 159 grains.

The pyroxyline from No. 1 was insoluble in glacial acetic acid, whilst that from No. 5, on the other hand, was easily soluble in the same reagent. Mr. Hadow therefore in his report stated it as his opinion that the mixtures were not of the same strength, but that No. 1 produced the compound which he terms compound B, standing next to gun-cotton, whilst No. 5 produced compound C, two steps removed from gun-cotton.

It thus appeared that a discrepancy existed between our own results and those of Mr. Hadow, for in the former the products were all soluble in glacial acetic acid. The gain in weight had also been different in the previous experiments, viz., about sixty per cent. in the case of No. 1, instead of sixty-nine per cent. This discrepancy, however, had been foreseen. Knowing that the cottons were to be left in the cold mixtures twenty-four hours instead of one hour, we had stated to Mr. Hadow, before he commenced his analysis, that probably he would obtain a higher substitution compound in the mixture No. 1 than in the mixture No. 5.

That the pyroxyline ordinarily made by the formula No. 1, which the Collodion Committee examined, is not the high compound nearly approaching to gun-cotton is certain; for, in testing it on many occasions, it has always been found soluble in glacial acetic acid, and also in boiling alcohol of ·805. The quantity of water also which is contained in the acid mixture No. 1 forbids the supposition of the highest compound being formed, for this water may be very materially reduced without rendering the pyroxyline insoluble in ether and alcohol. The mode in which the pyroxyline burns is another proof of the correctness of the above assertion, since we find that the pyroxyline from mixture No. 1 burns comparatively slowly, and is not at all explosive.

It may therefore be concluded beyond doubt that this first mixture, when employed in the ordinary manner, yields a rather low substitution body; and it remains to be explained how it happened that a higher compound, not acted upon by glacial acetic acid, could be prepared from it.

On taking fifty grains of dry cotton and immersing it at 60° F. in mixture No. 1 for a period of ten minutes, it was found to increase to seventy-five grains, but the product was very imperfectly acted upon by ether and alcohol, leaving behind fibres of unchanged cotton. A second portion of fifty grains, immersed for an hour, weighed afterwards eighty grains, and was dissolved by the ethereal mixture, with the exception of a few floating fibres: this pyroxyline liquified to a gummy mass under the action of acetic acid. In Mr. Hadow's experiment, after twenty-four hours' immersion, fifty grains became nearly eighty-five grains, and the product dissolved absolutely in ether and alcohol, but was unaffected by acetic acid. The foregoing facts seem to confirm the idea previously entertained, that when nitric acid is brought to bear upon cotton it acts by successive stages, forming, first the xyloidine, then the compound next above it, afterwards one still higher, until a point is reached beyond which the dilution of the acid forbids a further rise.

It will, perhaps, occur to the reader that if the observation above made be true it must apply to any mixture of nitrosulphuric acid, and therefore if twenty-four hours' immersion gave a higher compound than one hour's immersion in the case of mixture No. 1, it ought likewise to have produced a higher compound in the case of No. 5. On consideration, however, this argument does not appear to be sound; for, on comparing the two mixtures, we see that the proportion of nitric acid constitutes scarcely more than one-fifth of the whole bulk of the mixture No. 1, whereas in the case of No. 5 three-fourths of the liquid consist of nitric acid. Now, in the ordinary way of preparing pyroxyline the cotton imbibes the liquid like a sponge, and that portion of the nitric acid which comes in contact with the fibre acts upon it and converts it into pyroxyline. The great bulk of the liquid, however, scarcely touches the cotton, unless it be left a long time in the acid and be well stirred about with a rod. The consequence of this imperfect diffusion must be that a short immersion cannot afford a true criterion of the actual strength of the mixture when the proportion of nitric acid is reduced below a certain point, and a weaker substitution compound than theory would indicate is produced in such a mixture, simply because the nitric acid, being small in quantity, is *exhausted* at the point where it touches the fibre. Hence we find practically in working by the formula now under discussion that it is difficult to obtain a product *entirely* soluble in ether and alcohol; and if we reduce the time of immersion from ten minutes to five minutes the amount of undissolved matter becomes greater. With a mixture containing equal bulks of sulphuric acid and nitric acid the pyroxyline is soluble in ether and alcohol without leaving any sediment, even when the amount of water in the acids is carried far enough to produce a partially opaque film of xyloidine.

We are still of opinion that the table of acids before given is correct in all cases when the pyroxyline is made by a short immersion; but the experiments of Mr. Hadow, taken in conjunction with our own, appear to show that two different substitution bodies may be made in the same acid by varying the time of immersion.

ON THE PREPARATION AND MANAGEMENT OF THE NITRATE BATH.

By N. Gordon.

Prepare with fused nitrate of silver, in preference to crystallised, as it gives better density than the other. Saturate with iodide of silver.

In travelling the bath occasionally becomes acid, in which case it is a good plan to have ready collodion iodised with magnesium: use this in preference to neutralising the bath with carbonate of soda, as it would then require filtering. By the course I recommend you avoid this waste of time, as with a bath holding a large quantity it is impossible to draw it off, and filter, without carrying with you a large bottle, syphon, &c., for this purpose.

It is of course the best plan to get the proper density for printing, if possible; but I find that, in so doing, the details are often so overloaded with silver that the negative takes a very long time to print, and the proper contrast between the lights and shadows is lost. My plan is, after I see all the details of the picture are *well* out, to run the developer once over the negative again, then wash and fix.

When I require to print from a negative without the proper density, I put it against a window, leaning it on the edge of the sash, and taking a piece of thin blotting paper, I draw a line with a pencil over the outline of the picture, cut it out, then put the negative into the pressure frame, and the paper with the sky outline *over the outside glass* of the pressure frame. By this means you get clean skies, without any touching or painting the negative itself.

As an iron developer, I use the saccharo-sulphate: it developes more evenly than protosulphate, and, from the organic matter contained, gives greater density; it can also be kept longer on the plate, as the nitrate of silver is decomposed by it much less rapidly than with the protosulphate. As to paper, about which so many complaints are made, I recommend a trial of Mr. Hughes's, of Oxford Street.

ON THE ENLARGEMENT OF NEGATIVES.

By M. Bertsch.

In the enlargement of the negative (for which I am indebted to the kindness of M. Ferrier) I have been limited neither by the want of sharpness in the image nor by the fear of fringes of diffraction, but solely by the dimensions of the glass and by the distance at

my disposal. In the same manner as with my microscopical proofs, I have made use of parallel rays of light, and the apparatus the construction of which I explained at one of our former meetings.

Experience taught me long ago that, with the proper conditions of light which I adopt, the enlargement has no other limits than the appearance of the molecular arrangement of the substance used for the support of the small negative. When the light is quite parallel there is, consequently, no possibility of any refraction by the glass supporting the negative,—we only begin to see the structure of the film on an amplification of 2500 superficial dimensions for collodion, and 6400 dimensions for albumen.

In order to obtain the sharp appearance which is to be discerned in this proof, it is necessary to act in the shortest possible time (the one before us was only exposed a quarter of a second). This is required on account of the shaking occasioned by the traffic in the streets, and particularly on account of the progression of the sun. On the least advance of the latter, the axis of the rays ceases to be perpendicular on the posterior face of the negative, refraction is perceived, and the image on the screen displaced. It is on this account that I have always protested against the mode of illuminating at present in use; for, even without the movement of the sun, it causes unequal refractions from the centre to the circumference, and has, consequently, the effect of spoiling the image by producing multitudinous outlines of the object.

I beg to add that, even with the most favourable circumstances of which we can avail ourselves, it will be impossible, with substances of little sensibility, to obtain a sharp proof without the use of a heliostat, which exactly maintains the rays in the axis of the optical system.

If the proofs presented by M. Delessert (although possessing powerful artistic effect) are not quite sharp, it is neither to the imperfection of the negative nor to the aberration of the lens, and still less to the artist's want of precaution, that this fault must be attributed, but to the length of the time of exposure, and to the incomplete construction of the apparatus of which our clever colleague has made use.

In employing paper, prepared with chloride of silver (which at the end of twenty minutes is not sufficiently affected), it will be absolutely necessary to make use of the heliostat. A cross of platina wires fixed at the principal focus of the lens, and kept, during the time of exposure, in constant superposition on a similar cross placed at the summit of the outer cone, will answer the purpose; but this requires great patience on the part of the operator, and a perfect precision in all his movements.

Damp negative paper, such as is prepared at the present day, possesses sufficient rapidity for giving excellent proofs, and, by gold toning, will produce very harmonious shades.

People are greatly mistaken if they think that the enlargement of photographic negatives is but simple play-work, or a curious experiment of the laboratory. On the contrary, it merits the serious attention of the Society; for, according to my opinion, it will powerfully affect the future of our art, and is destined to greatly extend its practice, as well as to render certain very remarkable results.

If, by applying the processes of enlargement to the study of natural history with the microscope, I have been enabled to reproduce, with considerable dimensions, invisible beings, the infinite details of which would dishearten the most clever engraver—if they have further enabled me to solve some questions of physiology greatly interesting to science, I have not the least doubt that, when transferred to the domain of art, they will become of great assistance and very useful.

I have already addressed you on this subject several times, and have likewise opposed certain errors: my reason for doing so is, that, having had ten years' experience, I am enabled to trace a safer road to beginners than they have hitherto found.

Let us therefore communicate our discoveries and ideas to each other, and we shall not fail to cause the Science of Photography, so useful to every art, to be more generally applied.

The stereoscopic proofs, which one of our colleagues, M. Ferrier, has brought to so high a degree of perfection, have naturally suggested the idea of enlarging them, whilst, at the same time, we preserve their great sharpness.

In carefully studying the effects of the instrument which produces their relief, I have acquired the conviction that the theory of Sir David Brewster, although the only one that is admissible, does not give sufficient reasons for this phenomenon. I therefore beg leave to complete it by a remark which, moreover, greatly concerns the question of enlargement.

Artists particularly find fault with our photographic proofs on account of their being deficient in aërial perspective; and they are right. Several photographers have attributed this fault to the sensitive surfaces which, they say, are proportionally more affected by the light of the foreground than by that of the more distant parts. But, in my opinion, they are wrong; for the remotest part of the landscape sending even to our eye a greater amount of light than the foreground, the glass reproduces only the same scale of the luminous intensities which exists in nature, and can therefore not be made responsible for this want of harmony.

Others have pretended that the great sharpness of the horizon makes us bad judges of depth, when drawing conclusions as to distance; but far-sighted persons see the background of a landscape as clearly as the camera can produce it, and this is in no way injurious to the idea of distance. The reason for this want of harmony must therefore be sought elsewhere. You must have remarked that the larger the proofs are the greater is the defect in the perspective. Well, the chemical processes being the same for the large proofs as for small ones, it is to the optical arrangements that this fault must be attributed. We may remark that the more extended a proof is the more it will fall short in the foreground on account of the exigencies of the optical laws. Consequently, the sensation of extension is determined for us by the dimensions, the details, and the sharpness of the *foreground.* Isolated from it we can form no idea of distance.

The lenses which produce images of seventeen inches in diameter have a focus of at least thirty-nine inches, so that for them infinity, that is to say, the limit of sharpness most attainable, can hardly commence at a less distance than four or five hundred yards. All that is nearer is not strictly in focus, and must almost be entirely suppressed in the proof. *Our* distinct view, on the contrary, beginning at a very small distance from our eye, you will easily understand why there can be no comparison between a landscape as rendered by the camera and the same as we see it in nature. It is this variance which produces the deficient perspective in photographs. When we distinctly perceive objects which are near us, and which stand in the foreground, we can appreciate their real dimensions; and it is only by comparing their dimensions with that of similar or analogous objects, standing in different planes and continually decreasing in size, that we obtain the sensation of depth. This is so true that artists, painting panoramas, will never fail to place some living object on the canvas before the eyes of the spectator, in order that he may feel and understand distance, by instinctively comparing the dimensions of the real object with those of the objects painted.

For example: the angle of vision subtended by a house which, at a distance of about 300 yards, stands in the foreground, and the angle which embraces a house which we may suppose to be nearly similar in size, but which is situated near the horizon, are not sufficiently different to give us a clear idea of depth. The comparison of our best process with a Canaletti, for instance, will be quite sufficient to prove the truth of my statement. You will see, without the necessity of any further remarks, that the marvellous effect of the stereoscope is partly due to the more natural proportion existing between the fore and the background of the proofs, a proportion preserved in the amplification which the instrument causes them to undergo; and you will perceive of what an immense advantage it will be if for landscapes we make use of lenses the distinct view of which, if I may be allowed to make use of the expression, commences very near to our eye, that is to say, with lenses of short focus. You will likewise understand why I say that the effect of the stereoscope is not wholly due to the somewhat different angles under which we perceive the two images, but also to the relatively nearer situation of the foreground, which, when these images are a little enlarged, will produce in our eyes the same sensation as that which they receive from nature itself. In order to heighten the artistic effect and the appearance of truth, it will therefore be necessary to take our negatives with lenses of short focus, and afterwards enlarge them considerably. The greater the difference in size between the negative and the proof, the more we shall perceive the aërial perspective. With a view to solving this interesting problem for as many people as possible, I am at present constructing a camera for the use of travellers, which I will exhibit at our next meeting.

Not wishing to take up your time unnecessarily, I will only state, on the present occasion, that this camera, being regulated by micrometrical arrangements, will, in the hands of the operator, be like a veritable eye, the distinct view of which begins at the distance of a few yards; that the size of it will be about three inches;

that it will produce images mathematically, in the focus for all planes on a surface of two and one-third inches square; and that to make use of it it will not be necessary to possess much knowledge either of optics or of photography. Painters and tourists will thus be enabled to bring back from their travels any object from which they can retire a few steps only, and this without being encumbered by any luggage, without soiling their fingers with our materials, nay, even without looking into the little chamber.

THE SOLAR ECLIPSE.

[THE interest attaching to the total eclipse of the sun on the 18th ult. is still undiminished; and therefore no apology is needed for presenting to our readers, *in extenso*, the following lengthy but important letter, written to *The Times*, by Mr. E. J. Lowe, the eminent astronomer, one of the scientific gentlemen who accompanied the Astronomer Royal to Spain.—ED.]

SIR,—A total eclipse of the sun is a phenomenon which attracts universal attention, and being of rare occurrence, and more especially so in any particular spot, when such an eclipse does take place an excitement is caused so great that it takes precedence in the minds of men over everything else, for that day at least. It will therefore, doubtless, interest your readers to hear something regarding the great eclipse of the 18th of July.

Before describing this particular eclipse, allow me to say a few words on eclipses in general. In the present age, unlike olden times (when a superstitious dread filled the minds of men on such occasions), we all know more or less about eclipses; we have learnt that a solar eclipse is nothing more nor less than the body of the moon passing between us and the sun, and that a lunar eclipse is caused by the earth passing between the sun and the moon, and thus preventing the sun shining upon it, or, in other words, the earth casts a shadow upon the moon, and this shadow is the darkness which we see upon the moon in a lunar eclipse. Perhaps, however, it is not universally known that the same eclipses recur every 18 years and ten and a half days. These eclipses will differ in magnitude, and they will occur more or less irregularly. Seventy eclipses usually take place during the 18 years, those of the sun being 41, and those of the moon 29. Reading this in an astronomical work, the public naturally conclude that solar eclipses are common; but on account of the moon's body being smaller than that of the sun, her shadow is a cone, tapering to a point, and as the distance between the earth and moon slightly varies, it happens that this point of the moon's conical shadow sometimes does, and sometimes does not, reach the earth, and when it does its dimensions are inconsiderable. Consequently, a total eclipse is a rare phenomenon, and, further, being limited in extent, it is even more rare at any one locality. The immortal Halley, in describing the total eclipse of the sun in London of the 3rd of May, 1715, remarked that previously none had been total in London since March 20, 1140, a period of nearly 600 years. To take an example of the recurring period of 18 years, by comparing the year 1842 with the present year 1860, we have the following eclipses recurring:—An annular solar eclipse, 1842, January 11, and 1860, January 22; a partial lunar eclipse, 1842, January 26, and 1860, February 6; a total solar eclipse, 1842, July 7, and 1860, July 18; a partial lunar eclipse, 1842, July 21, and 1860, August 1; an annular solar eclipse, 1842, December 31, and 1861, January 10.

The period of totality of a solar eclipse can never exceed 7m. 58s. under the equator, and not above 6m. in this island, so that even when we are fortunate enough to witness a total eclipse of the sun, its duration is necessarily very short, and consequently phenomena of a wonderful character are so crowded together that before there is time to make a proper record daylight has returned, and shut out these singular appearances. Indeed, the sights to be seen during these brief minutes are of so imposing a nature that it is only the steady astronomer who can look and record what he sees, for on no occasion is the motto of the Royal Astronomical Society (*"Quidquid nitit notandum"*) more difficult to be obeyed than during a total solar eclipse.

Returning to the present eclipse, the line of totality enters North America from the Pacific Ocean at Astoria, in Oregon, passes across North America to Cape Chudleigh, in Labrador, and across the North Atlantic Ocean (the line lying to the south of Greenland), enters Spain about Gijon, Santander, and Bilbao, crosses Reynosa, Arnedo, Calatayud, Daroca, Montalvan, Morella, and Oropesa, enters the Mediterranean, crosses the Island of Ivica, and grazes the south edge of Majorca, passes into Algeria, and ends near the Red Sea. The breadth of the line of totality is great; the southern limit in Spain extends considerably beyond Oviedo and Valencia, while the northern limit extends beyond Tortosa and nearly reaches Pampeluna.

Previous to describing the expedition and the observations made in Spain, it will be necessary to say a few words regarding the instruments. My own department was meteorology, and the making of the whole of the instruments was intrusted to the care of Messrs. Negretti and Zambra, opticians, Hatton Garden; and I must add that my confidence with regard to the skill of this well-known firm was not misplaced. These instruments consist of a standard barometer, patent *maximum* and *minimum* thermometers placed at one, two, three, and four feet above the ground, both in sunshine and shade, self-registering *maximum* and *minimum* wet and dry bulb thermometers, vacuum thermometers, thermometers made expressly for plunging various depths into the ground, and a series of blackened bulb thermometers; a Robinson's anemometer, to show the velocity in miles of the movement of the air, and a Lowe's ozone box—the wind vane being a light silk flag. These instruments were read off, as previously arranged, every five minutes, from twelve o'clock till five o'clock, by myself and the Rev. W. R. Almond, F.R.A.S., and Mr. Samuel Morley, my assistants, accurate time being kept by a most excellent duplex watch, made by Mr. J. Bennett, of Cheapside—a maker whose watches I have used with satisfaction for some years. The thermometers were placed on a Lawson thermometer stand, made portable for this expedition. For photographic observations, salted papers (sensitised before leaving England) were conveyed in the patent preservative case of M. Marion, of Regent Street, and were exposed constantly during the progress of the eclipse. Besides these, the variously-prepared dry plates (*i. e.*, collodio-albumen, metagelatine, Fothergill's, and those of the Birmingham Dry Plate Company) were taken out for exposure in the stereoscopic camera known as Dancer's patent. These dry plates will be interesting in more ways than one, as they will be the means of recording pictorially the place of observation and places of interest passed over by the present expedition.

It will be necessary to add that the observers were distributed in various directions. A large portion which landed at Bilbao, including the Astronomer Royal, have not as yet been heard of since the eclipse. Those observers who landed at Santander took up positions—some at Santander, others at Alar del Rey; Mr. Lassell at Aguilar de Campo; the Swedish astronomers at Escudo Pass; Professor Swann, Mr. Ellis, and myself, at Fuente del Mar; Mr. Heath at Pena Castilla; Mr. J. Mould at Los Corrales; and a staff of observers, under Captain Seccombe, opposite the anchorage of the Himalaya. At Fuente del Mar, the beginning of the eclipse was well seen. Exactly one minute before totality clouds hid the sun, and the celestial phenomena were lost; but, owing to large spaces of clear sky, the terrestrial phenomena were grandly visible, and our whole attention was riveted upon them. Fortunately, a mile from here the observers at the Himalaya had a fine view of totality, stars became visible, together with the red prominences and corona.

The following is a record of the readings of the different instruments, and, as they are taken from above 4000 observations, made by myself and assistants during five hours, they must prove of great value. Commencing with underground temperature, a thermometer placed 6 inches below the surface of the ground ranged between 67·9 deg. and 70·7 deg.—*i.e.*, 2·8 deg.; at this depth the eclipse was not sensibly felt, whereas other thermometers, placed 4 inches, 2 inches, 1 inch, and half an inch below the surface, all exhibited in a very marked manner the effect of the eclipse. On the grass the temperature fell to 64 deg. at 3h. 5m.; at half-an-inch below the surface to 69 deg. at 3h. 15m.; at 1 inch deep to 69·5 deg. at 3h. 15m.; at 2 inches to 71 deg. at 3h. 55m.; and at 4 inches to 70·7 deg. at 4h. 30m. p.m.

The temperature on grass was 77·5 deg. at noon, rising to 91·7 at 1h. 50m., and then falling till 3h. 5m., and again rising to 85 deg. at 4h. 10m., giving a range of 27·7 deg. At half an inch below the surface of the ground the temperature rose till 1h. 55m. p.m., when it was 78.5 deg., and then gradually fell to 69 deg. at 3h. 15m., rising again to 74·7 deg. at 4h. 30m. p.m., the range being 9·5 deg. At 1 inch below the surface, the temperature rose till 1h. 55m. to 76·2 deg., fell till 3h. 25m. to 69·5 deg., and rose till 4h. 55m. to 74·7 deg., the range being 6·7 deg.; at 2 inches below the surface the temperature rose till 2h. 5m.—viz., to 74·4 deg., then fell till 3h. 55m. to 71·0 deg.; and afterwards rose till 4h. 55m. to 73·7 deg., the range being 3·4 deg., and at 4 inches below the surface the temperature rose till 2h. 50m. to 73 deg., then fell till 4h. 30m. to 70·7 deg., and again rose till 6 p.m. to 73·2 deg., the range being 2·5 deg.

The greatest cold on the ground occurred between 3h. and 3h. 5m. p.m.; ditto, half-inch below surface, 3h. 10m. and 3h. 15m. p.m.; ditto, 1 inch, 3h. 20m. and 3h. 25m. p.m.; ditto, 2 inches, 3h. 50m. and 3h. 55m. p.m.; ditto, 4 inches, 4h. 25m. and 4h. 30m. p.m.

Temperature.	Commencement of Eclipse.	Middle of Eclipse.	End of Eclipse.	Range during Eclipse.
	Deg.	Deg.	Deg.	Deg.
Of a blackened ball on grass	104·0	65·5	94·0	38·5
Of a blackened ball in vacuo	131·0	66·0	104·0	65·0
In sunshine at 2 feet	75·5	63·6	70·0	11·9
In sunshine at 2 feet, wet bulb	69·5	59·3	65·5	10·2
Difference between dry and wet bulb at 2 feet	6·0	4·4	4·5	1·6
In shade at 4 feet	70·0	64·7	71·0	6·3
In shade at 4 feet, wet bulb	62·5	59·7	63·5	3·8
In shade at 3 feet	70·2	64·2	70·7	6·5
In shade at 2 feet	68·5	62·5	68·5	6·0
In shade at 1 foot	70·7	64·5	70·2	5·7

The barometer rose from 1h. 40m. till 2h. 10m. 0·002 inch, then fell till 3h. 5m. 0·017 inch, and rose till end of eclipse 0·009 inch.

Intensity of photographic light from salted papers conveyed sensitised in Marion's dark box, exposed for 10 seconds (with a scale of 0 to 5 deg.), at the commencement of the eclipse, $4\frac{1}{4}$ deg., becoming 4 deg. at 2h. 5m., 3 deg. at 2h. 15m., 2 deg. at 2h. 25m., 1 deg. at 2h. 40m., $0\frac{3}{4}$ deg. at 2h. 50m., 1 deg. at 2h. 55m. (clear about sun), $0\frac{1}{4}$ deg. at 3h., 1 deg. at 3h. 5m., 2 deg. at 3h. 25m., $2\frac{1}{2}$ deg. at 3h. 40m., 3 deg. at 3h. 50m., and 4 deg. at 4h. During totality a paper exposed for one minute gave $0\frac{3}{4}$ deg.

The wind was N.W. and N.N.W. till 4h. 20m., then W.S.W., becoming S.W. at 4h. 25m., and S. at 4h. 45m. The wind was brisk at the commencement of the eclipse, quite a calm during totality, and a gentle breeze afterwards. The distant prospect was very clear, except during totality, when the mountains disappeared and only near objects were visible.

The clouds, which were chiefly cumuli, diminished in amount till 1h. 50m., when only four-tenths of the sky was overcast, then increased till 2h. 35m., with much cloud till 3h. 55m., then again diminished to six-tenths at the termination of the eclipse, the range being 5·5 tenths of the whole sky. Towards totality some of the cumuli became scud, which lasted from 2h. 5m. till 3h. 10m., giving the strongest impression that the change was due to the eclipse.

The morning was fine, and from 12h. 45m. p.m. sunshine; at 1h. 25m. much open sky about the zenith, 2h. 15m. a blackness about W. horizon, and slightly so in N. and S., at 2h. 30m. the hills dark, and the blue sky in N. and E. very pale in colour; 2h. 35m., hills dark, with a blue haze among the more distant mountains; 2h. 40m., horizon due W. pink; 2h. 45m., clear sky in N., pink; 2h. 52m., splendid pink on W. horizon, warm purple on summits of mountains in S., clear sky; in N. deep lilac, and in E. very pale blue; 2h. 57m., rapid change, the clear sky in N. deep marine blue with a red tint.

Before totality commenced the colours in the sky and on the hills were magnificent beyond all description; the clear sky in N. assumed a deep indigo colour, while in W. the horizon was pitch-black (like night). In the E. the clear sky was very pale blue, with orange and red like sunrise, and the hills in S. were very red; on the shadow sweeping across, the deep blue in N. changed like magic to pale sunrise tints of orange and red, while the sunrise appearance in E. had changed to indigo. The colours increased in brilliancy near the horizon, overhead the sky was leaden. Some white houses at a little distance were brought nearer, and assumed a warm yellow tint; the darkness was great; thermometers could not be read. The countenances of men were of a livid pink. The Spaniards lay down, and their children screamed with fear; fowls hastened to roost, ducks clustered together, pigeons dashed against the sides of the houses, flowers closed (Hibiscus Africanus as early as 2h. 5m.); at 2h. 52m. cocks began to crow (ceasing at 2h. 57m., and recommencing at 3h. 5m.). As darkness came on many butterflies which were seen about flew as if drunk, and at last disappeared; the air became very humid, so much so that the grass felt to one of the observers as if recently rained upon. So many facts have been noticed and recorded, that it is impossible to do more than give a brief statement of the leading features. At 5h. 55m. a mock sun was formed 22 deg. below the true sun, having the ordinary circular form. From the summit of Pena Castilla, overlooking the Bay of Biscay, Mr. Heath noticed the magnificence of the colouring of the sky reflected in the sea, while the water near us was of a deep leaden hue, owing to clouds overhead.

I am indebted to Mr. Thompson, master of Her Majesty's ship Himalaya, for the following telescopic observations:—

Totality commenced at 2h. 52m. 55s., when prominences were visible, one on the west and two on the east, of a bright lurid lake colour, followed by the corona shooting out on the east of the sun in two forked tongues. The colour of the corona was white darting outwards. Towards the end of totality another prominence was noticed on the west side of the sun, of the same colour as those first seen; and below this a most beautiful collection, as of golden beads closely strung together, shone out, extending to the lowest part of the western limit of the sun. The stars numbered 7 and 8 in Mr. Hind's map were distinctly visible in the telescope. The cusps of the sun were rounded before and after totality, and the prominences were lurid and well defined. A very considerable variation of the compass took place during the eclipse.

Lieutenant N. C. Barton, of the same ship, has kindly communicated a few of the notes made by him during the eclipse Venus appeared shining very brightly in the midst of the totality at 2h. 59m. 56s. Pollux also was seen at 3h. 0m. 24s., but was only in sight four or five seconds, in consequence of a cloud overcasting it. Three red protuberances showed during totality to the left of the sun, the upper one being very bright. Some beads were also observed, of a light, shining character—very like a diamond necklace worn by a negro belle.

At Los Corrales, Mr. J. Mould remarked that the blue sky over Santander appeared a very dark indigo, afterwards changing to a deep amber, and was most beautiful; that his fowls began to march "*a cama*," but, light coming on, they returned to their usual occupation. The temperature in sun ranged on the grass between 109 deg. and 62 deg Before totality the sky became overcast

Before I conclude this letter, written from an arbour in the pleasant grounds of Mr. J. P. Sewell, managing representative of Mr. Mould, overlooking Santander harbour, where rides the magnificent Himalaya, it becomes me, in the name of the party to which I am attached, to return our most grateful thanks, not only to Mr. Sewell for his generous

hospitality, extending over a whole fortnight, and for the facilities which, from his high position, he has been able to afford us in the pursuit of our aims, but also to Lieutenant March, the British Vice-Consul, to the authorities of the port, and to the inhabitants, who have received us with a cordiality and urbanity which has been highly gratifying. It may be recorded, as perhaps a valuable hint to the managers of our own companies, that, immediately on our arrival, free passes were sent by the railway directors, not only to the astronomers, but to all the officers of the ship, enabling us and them to travel wherever we liked upon the Ferro-Carril de Isabel II. between Santander and Alar, with this liberal endorsement, "*Durante su permanencia en Espana*," a boon of which I need scarcely say we have taken every advantage. To all the staff on the line our thanks are due for the unbounded trouble which they have taken in furthering our endeavours to fix upon eligible sites for observation, and in facilitating our general arrangements.

I have the honour to be, sir, your obedient servant,

E. J. LOWE.

Fuente del Mar, near Santander, North Spain, July 19.

MESSRS. SPILLER AND CROOKES' EXPERIMENTS.

MESSRS. SPILLER and CROOKES having determined to co-operate in obtaining photographs of the different phases of the solar eclipse, commenced their arrangements in the grounds of the Royal Arsenal at Woolwich, at an early hour on the morning of Wednesday, the 18th ult. The apparatus employed was the small equatorial belonging to the Military Repository, which has an object glass of four inches diameter, having a focus of six feet, and was mounted on a stand with screw adjustments for altitude and azimuth; the eye-piece was removed and a quarter-plate camera attached to its tube. After various trials, it was found necessary to reduce the aperture, by means of card diaphragms, to one-fourth part of an inch, and to give exposures of only $\frac{1}{1000}$ part of a second before perfect pictures could be obtained. That no delay might arise in the operations, all the apparatus, baths, &c., were arranged in duplicate, in a manipulating room, well lighted by means of yellow glass windows. Mr. Spiller gave his attention to the adjustment of the camera and frame; Mr. Crookes to the exposure of the plate. At the moment of first contact, the phenomenon was obscured by a passing cloud; but in a few minutes it was revealed to view, with decided evidences of the eclipse having commenced, and from this point to its termination plates were exposed about every five minutes. One of the most successful of this series was obtained at 2h. 48m., that being the moment of greatest obscuration, and represents the sun as *a sharp* crescent, the edge presenting a marked contrast with the serrated mountainous edge of the moon then creeping over its surface. About this period these gentlemen noticed a curious phenomenon. Spots of sunshine, falling through the foliage, usually present a circular form in the shade beneath, being in fact minute images of the sun; but they observed that the ground beneath some trees near them was studded with small *crescent-shaped* images of the eclipsed luminary, and surrounding objects were illuminated with an unearthly, ghastly yellow gleam, quite of an unusual character.

OUR EYE-WITNESS AT OXFORD.

As we have been called upon to fix our ideas of the British Association Meeting at Oxford, from a photographic point of view, we suppose it is incumbent upon us to try to fulfil that task; though we must confess that their development has not come out at all strongly; and, as we are sure that we focussed correctly, and exposed no less than the entire time of the meeting, we must lay the fault upon the absence of actinic influence in the matter before the meeting—which, considering the *locale*, seems strange.

We wish we had been in a position to do justice to the *embarras de richesse* which here presents itself to a photographer in search of a subject. He may gratify his taste whether his aspirations lead him in an architectural, archeological, antiquarian, sylvan, or domestic direction. He may fill his plate-box with Guy Faux lanthorns, prescriptions by Old Radcliffe, autographs of Calvin, Luther, or the skeleton of the great tunny fish sent to Dr. Ackland from Madeira, and which stands so conspicuously in the great quad. of the Museum, a natural prototype of the skeleton glass cases around it. The weather was not very propitious during the early part of the meeting, or we know not how many of these subjects we might have taken off; as it is, we have secured, with Dr. Norris's aid, only a few views of the interior of the Museum—that fairy-like structure which was deservedly the cynosure of all its visitants. We spent three or four pleasant evenings there; and you, too, Mr. Editor, will not cavil at our appreciation of the rich treat afforded us by the inspection of some two hundred and fifty microscopes, with the varied objects on their stages. These were not so rare as rich; but it is an interesting sight to watch an assembly of this kind intent upon such an amusement. Young and old, thoughtless and grave, dignitaries and humble, all bend alike to the magic glass which reveals so much of the inner world in and around about us; and even the poor frog, whose circulation is exhibited to the pleasure of hundreds, but to its own pain, becomes quite a curiosity for the nonce. But we prefer Messrs. Smith, Beck, and Beck's preparations, or Mr. Thomas's instruments, under which are shown the circulation in plants, also various *rotiferæ volvoces*, &c. A binocular microscope attracted our attention also, and most of all, some decomposed glass, from Nineveh, &c., exhibiting all the colours usually displayed by polarised light. This was shown by Sir David Brewster, a veteran whom we were delighted to meet once more, apparently in vigorous health;—long may he live to enjoy the honours of a hale old age! Then there were photographs by Hill, of Cornmarket Street, Oxford, of various portions of the interior of the building, principally capitals and spandrils. If Mr. Hill could be induced to publish these at a cheap rate, we should commend them to every mason who desires to raise himself above the level of his craft, and emulate the brothers O'Shea, whose hands have been so active in this really beautiful building. Then there were Mr. Fenton's (we beg his pardon, Captain Fenton's) views of the exterior of the building; and we heard stories of his travelling apparatus, and of his horse, whose immovability must be a special development adapted to the photographic propensities of his master. Professor Hochstetter exhibited some photographs from New Zealand, the names of which we cannot recall to mind at all—chiefly scenery of a not very interesting character, and but indifferent specimens of photography. When we have referred to the electrical experiments by Mr. Ladd, we have exhausted all that need be said of the *soirées* of this meeting, which were brilliant in point of place and company, but rather deficient in regard to scientific attractions.

We attended Professor Walker's Discourse on the Sun, a paper which, of course, opens upon an immense field of controversy; but we gathered from it that, as far as doctors are *agreed* on the subject, there is a long extended future for photographers, and that solar influences will continue to abound with sustained if not increasing actinic power.

Captain Osborn's attractive lecture on Arctic Discovery, and the recital of the Franklin Prize Poem, and the Conferring of the Degrees, did not reveal any photographic mysteries to us, but we rejoiced to assist at the ceremony which dignified the three *literati* whose names are household words—Wrottesley, De La Rive, Sedgwick, form a triumvirate of *savants* long to be held in honourable remembrance. Of course we wandered over the courts and quads. of the University, seeing (with regret that we could not take all of them home with us) many characteristic bits extremely worthy as objects for the camera:—the beautiful gates of St. Mary's—the fine entrance to the Hall at Oriel—the Statue in Brazennose Quad.—the Cathedral—the Tower and Bridge at Magdalen—the magnificent avenue at Christ Church—the University Boat Club Barge, &c., being among these.

Then we followed the Oxford City Rifles to their drill-ground. We wonder if it has occurred to any one to test invisibility by the effect produced by a body of men in the camera: it would be the *experimentum crucis* in this direction. We never yet saw any Volunteers whose dress came up to our idea of indistinctness; certainly the Oxonians have not attained this. The members of their band exhibit the extremes of conspicuosity, with their scarlet peg tops and plumes; but then bands would not be permitted on the field.

We must not omit to mention that we included a trip to Banbury in our photographic ramble. The good people of Caketown have, in their desire to keep up the remembrance of the good old times, erected a cross, to which the Oddfellows made a pilgrimage on the 3rd of July, and the Lady with "rings on her fingers and bells on her toes" was also duly personified.

We also remember our trip to Blenheim, and long for another opportunity of visiting it with our camera. For forest scenery we think this fine place can hardly be exceeded; and as trees are somewhat difficult to manage, we recommend our friends to try their hands there.

We had got thus far with our paper when we received yours of the 15th ult., in which you have really exhausted the photographic business of the Association, which certainly was very meagre, and especially so remembering what Professor Owen said at Leeds, from which we should have hoped better things: as it was, photography was chiefly conspicuous by its absence. Perhaps Mr. Darwin's theory of natural selection had something to do with this. We feel satisfied our Manchester friends will do their best to wipe away the reproach which seems to attach to photographers in general. Their vocation, being essentially peripatetic, should receive due notice in the proceedings of a body so peripatetic as the British Association.

Altogether we shall bear pleasantly in mind our Oxford excursion. If it was not productive of much practical photographic good, it wrought some benefit in making us several new friends, and helping to that reinvigoration of body of which we stand much in need at times. Σ

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING THE PHOTOGRAPHIC IMAGE.

Report of the Committee, consisting of Messrs. MASKELYNE, HADOW, HARDWICH, *and* LLEWELYN.

(Continued from page 207.)

THE processes which seemed to hold out the greatest prospect of success for the production in the first place of a suboxide, and subsequently of a sub-chloride, by the methods of the laboratory, and independently of the action of the light, were those afforded by the reduction* of the citrate of silver, and by the conversion of arsenite of silver† by the action of a caustic alkali into alkaline arseniate, accompanied by a reduction of the oxide of silver to a mixture of metallic silver and suboxide, thus:—

$$3\ AgO\ AsO_3 + 3NaO\ HO = 3\ Na\ O\ AsO_5 + Ag_2\ O + Ag.\ ‡$$

Of the results yielded by the first of these, none were found that gave any promise at all satisfactory. Hydrogen was passed through citrate of silver suspended in hot water. The products, at first brown, and then black, and finally grey, were examined at various stages of their progress in coloration, citric acid being used as a solvent to remove the citrate and the oxide,§ the residuary product being examined by treatment with dilute chlorhydric acid to convert it into chloride. The citric acid solution was found to contain nothing capable of reducing permanganate of potash, and must therefore have been free from suboxide. The result of treating the residue with chlorhydric acid, and then dissolving the silver by dilute nitric acid, was a rose-tinted chloride of silver.

On the supposition that this residue was a mixture of suboxide, or a salt of it, with metallic silver, we are constrained to the view that the suboxide of silver is not characterised by the property of entirely passing, under the influence of chlorhydric acid, into subchloride. This seems to be confirmed in some degree by the results with the arsenite, to which we now proceed. To that reaction, which Wöhler has described, much attention was devoted; and it was tried under several modifications.‖ By forming a dilute solution of arsenite of silver in nitric acid, and adding this very gradually to a boiling concentrated solution of soda, an extremely black powder was produced. This on being treated with dilute chlorhydric acid becomes grey; and on boiling the washed product with dilute nitric acid, silver is dissolved, and there is left a substance which, if Wöhler be right in calling the black powder suboxide of silver, we should expect to contain subchloride of silver. The colour of this substance is a rich chocolate or maroon, more or less dark, according to the nature of the process: it never reached the deep slate-violet of the chloride of silver exposed to sunlight.

* Wöhler, Ann. Pharm. xxx. 3.

† Wöhler, Ann. Chem. Pharm. cl. 363.

‡ The formula for arsenite of silver usually accepted is 2 AgO AsO_3, but we find Wohler's formula as above given to be the correct one.

§ The brown product became converted into the black one by the treatment with citric acid. Both underwent similar changes under the successive action of chlorhydric and nitric acids, and both previous to this treatment reduced the permanganate of potash powerfully. But it was found that the citric acid alone was capable of reducing the deposit to the grey condition of metallic silver, withdrawing from it at the same time (all the) oxide of silver,—a result which seemed to render almost hopeless the effort to form the suboxide by its means.

Indeed the mere boiling of the citrate blackened it, producing a dark-coloured mixture of silver with some compound of the suboxide, the citrate itself undergoing a transformation which must have lowered its saturating power, as the solution remained neutral. The citrate, however, when thus boiled with water through which a stream of hydrogen was passing, became more darkly coloured, but imparted an acid reaction to the water.

The black body that results from the reactions described, contains organic matter, as it intumesces when heated. It cannot therefore be merely a mixture of metallic silver with the suboxide.

The dry citrate heated in a stream of hydrogen is very slowly affected at 212°, but passes at length into a substance which produces on the one hand a dark-brown solution, and on the other a brown residue which yields a very pale-red body on being transformed by chlorhydric and nitric acids.

‖ It appeared, in trying Wöhler's experiment in several ways, that on the one hand it was extremely difficult to get rid of all the arsenic compound from the residue, and on the other that the tendency of arsenic acid in solution was to further the breaking up of the suboxide into oxide and metal. Lime and baryta-water were therefore substituted for the soda, but still arsenite of silver remained undecomposed. This seemed due to its solid condition. It was to overcome this that the solution in nitric acid was adopted.

It was found, however, that the chocolate-tinted compound of chlorine and silver, by whatever process it had been produced, became, by fresh treatment with chlorhydric acid, again capable of yielding a solution of silver when treated by nitric acid. So utterly unstable are these subcompounds of that metal!

Indeed it would seem that, to secure to them any permanence, they must be formed in combination.

On analysis it was found to contain as large an amount as twenty-four per cent. of chlorine;

The pure chloride Ag Cl contains 24·74 of chlorine;
The subchloride Ag_2Cl requires 14·08 of chlorine.

Other products of less-deep hue than the one first examined gave the numbers 24·3 and 24·2 per cent. of chloride. Assuming that the chocolate hue was imparted to the substance by a subchloride (and no other view seems equally probable), we are constrained to recognise in this subchloride, only present to the amount at the furthest of five per cent., a surprising colorific energy.

From the experiments previously cited, we are disposed to think that our failure in this attempt to produce the pure subchloride of silver arose from the fact of the action of chlorhydric acid upon the suboxide of silver not being so simple as a complete conversion into subchloride would indicate; and we are the more induced to draw this conclusion from the analogy of the suboxide of mercury. Thus, if from a solution of the suboxide of mercury that oxide be precipited, the action of chlorhydric acid on the precipitate is not to form the subchloride, but a grey mixture of chloride and metallic mercury. The same may perhaps apply to suboxide of silver; and, if so, it would be decomposed by chlorhydric acid, either partially or entirely, and would form chloride of silver and metallic silver.

One experiment we tried, in the hope of producing the subchloride of silver by a direct reaction. Chloride of silver is soluble in concentrated and highly alkaline arsenite of soda; and this solution, in the presence of excess of soda, was gently warmed. A brilliant mirror-like deposit, not of subchloride, but of metallic silver, was the result.

But with however little success the efforts to produce a pure subchloride of silver have as yet been crowned, the experiments we have detailed enabled us to institute a few comparative reactions whereby the result of treating a true subchloride (however diluted, so to say, with protochloride) with the ordinary reagents employed by the photographist may be achieved. The results yielded by these reagents were the following:—

Nitric acid, of sufficient strength to dissolve silver by heat, does not alter this dark compound.

Chlorhydric acid does not, when dilute, produce any apparent change in it.

Ammonia breaks it up entirely, dissolving all as chloride, except a minute amount of metallic silver, which remains.

Hyposulphite of Soda dissolves all except a trace of metallic silver like that left by the ammonia.

It will hardly be worth while to go through the reactions exhibited by these several tests with the dark body formed by the photochemical decomposition of the chloride of silver, or of this body mixed with excess of nitrate; for we find that these reactions are in the several cases identical. The light-darkened chloride indeed presents a deeper and bluer colour than that formed artificially; but when it is considered that the light-formed body is a coating of uniformly and completely transformed substance—superficial it is true, but continuous in its surface—while the laboratory product is an intimate mixture of discontinuous particles, the bluer tint of the one and the redder tint of the other will hardly carry much weight in deciding against the identity of the colorific silver-compound in each case. Nor will it perhaps be considered to support the view of the photochemical reduction consisting in the complete severance of the metallic silver, that the product of that reduction can be formed by the light in the presence of nitric acid. The production of an allotropic form of silver in the nascent state, in the presence of nitric acid, seems certainly to make a larger demand on the credulity of the chemist than the assertion that the reduction stops at an intermediate stage, at which a subchloride is the result of it—a subchloride, whose properties we have seen to be identical with those of a substance formed in the laboratory, and to which it is difficult to assign any other composition than that of a subchloride of silver.

(To be continued.)

ON THE PRODUCTION OF COLOUR AND THE THEORY OF LIGHT.*

By JOHN SMITH, M.A.

THE author had come to the belief, by means of experiments, that colour is produced by alternate light and shade in various proportions. To prove this, he caused a white ray to revolve at various speeds on a black surface. His first experiment was to move a slip

* Abstract of papers read before the British Association, 1859, extracted from the official report, just published.

of white cardboard over a black surface. By this motion he obtained a distinct blue; afterwards, in different weather, the same thing produced a purple. He then made a disc with five concentric rings. One ring was painted one-third black, the rest of the ring being white; the next ring was two-thirds black and one-third white; the next was three-fourths black and one-fourth white, and the fifth half black and half white. This disc, when made to revolve, became completely coloured; there were no more blacks or whites visible, but five rings of different colours. On a bright day, with white clouds in the sky, the

1st ring was of a light green: much yellow.
2nd ring purple: very blue.
3rd ring nearly as first.
4th ring purple, darker than the 2nd.
5th ring pink.

By means of eccentric motions a great variety of colours were obtained; amongst others, a pure red, and various shades of purple, pink, yellow, and blue. The number of discs tried were very great, each disc having on it a different proportion of black and white.

The author produced the same results by cutting out spaces in the white card, and causing it to revolve on a black surface. He produced also similar phenomena by causing these figures to revolve when held perpendicularly, and to take the appearance of coloured solids. He also caused these colours to be reflected on a white surface from the revolving disc. These experiments, and the views drawn from them, were used for the purpose of giving a theory of the prism, to be published in detail. It was by such processes that the author was led to believe that he had demonstrated that colour is produced by a mixture of light and shadow at various intervals; and at last he was satisfied that the experiments were original, and not explicable by the present recognised laws.

He concluded in these words nearly:—Remarkable as these experiments are, they are not more remarkable than the results they lead to.

They prove the homogeneity of the ether.

They prove the undulatory hypothesis, but oppose the undulatory theory.

They show the necessity of introducing a negative element into the theory of colour, or that colour is the effect of two co-ordinate sensations—a positive and a negative.

They enable us to dispense with the different refrangibilities of the rays of light, taught by Newton.

They remove the necessity for the supposition of different lengths of waves or of a disposition in matter to produce waves of different lengths.

They help to explain many of the phenomena of what is called the polarisation of light.

They give a new explanation of prismatic refraction, and explain, in a plain and simple manner, many very interesting natural phenomena.

Startling, he said, as these conclusions are, to those who are conversant with the subject of light, he thought he was perfectly warranted in drawing them from his experiments.

PHOTOGRAPHY IN THE FAR SOUTH.

[We have been kindly permitted by the recipient to give the following interesting extract from a letter received from a photographic friend, resident in a populous city, many thousand miles from this country; but, as it was not written for publication, we are precluded from mentioning the precise locality, or the names of the parties referred to in the letter. It is always pleasant to know what our absent photographic brethren are doing with reference to our art. —Ed.]

My dear Friend,

* * * Photography goes on swimmingly. I have just been highly delighted by receiving, from London, a lot of apparatus exactly the reverse of what I had ordered. The camera is not portable, as ordered, and the lens does not cover the field. A novice might receive such a lot of things, and have gone mad over not getting the corners of his pictures clear. Why cannot they test their instruments before sending them out? The lens would cover the glass well enough, only there is such a pile of brass work behind it,—and it won't shoot round the corner. You will recollect Mr. ———'s instrument had the same defect, which we remedied by chipping out a 1000 feet or so of lumber, but the same cannot be done with brass work. I ordered a portable bellows camera, and received for answer that they were very unstable, requiring a complicated arrangement of struts, &c., to keep them firm. Is this a fact? Is there not such a thing made in England as a good portable camera? In France they can make them.

Another very pleasing alteration they made in my order was to send me a camera for pictures seven by nine inches, whereas I had ordered eight and a-half by six and a-half inches, and all my fittings here are for this latter size, and will, in consequence, have to be altered. Pleasant! isn't it? If you have a chance of seeing Messrs. ——— you can tell them that it is always best to execute orders exactly as sent, no matter how absurd they may seem, if they don't answer, the orderer can only blame himself.

Messrs. ——— are rebuilding their establishment on a grand scale. A new glass house is being put up on the top of the old place, and the former gallery is to be turned into a workshop. Picture-taking must be a profitable business. Although Messrs. ——— have not taken many pictures, they can afford over a thousand pounds in alterations already. Mr. ——— is astonishingly successful in getting dirty pictures, which seem to sell, however: you would not believe a Christian would use them for any purpose if you could see some of them. Mr. ———, our Scotch friend, is also doing something; but as he, for economy's sake, uses tin funnels to filter his silver bath, there is not much to be feared in that quarter. Mr. ——— has lately taken to pictures, but gets *an artist* to paint them over, in the style of some of your productions. As he uses plenty of bright colours his pictures are much admired. The new Ross lens you have sent out is a stunner: I have christened it the Whitworth gun, from its neatness and compactness. Your brother has had a small house built for it, in which I am thinking of taking lodgings next time I am burnt out. When are you going to send out some specimens of English landscape photographs? I should like to have a chance of making comparisons, and see whether your establishment here can lick them as completely in paper positives as they do in glass ditto. I received the other day a picture from home, which I felt inclined to trample upon the moment I saw it, it was such a villanous production. Is the sun so scarce with you? If it is, you should offer a premium to Niépce de St. Victor to induce him to perfect his invention of "bottling up" light; you could then advertise "direct importation of sunshine from the South Sea Islands!" and make a good thing of it.—I am, yours, &c. C. L. R.

EXPERIMENTS ON LATENT LIGHT.

By M. Thenard.

M. Thenard has communicated to the Philomathic Society the following experiments:—

1. In perfect darkness a sheet of ordinary paper was desolarised by exposing it for an hour to the action of steam.

2. The sheet of paper thus treated was divided into two parts: one was set aside to serve for comparison; the other was rolled up, and placed in a glass tube, into one end of which ozonised oxygen was passed. In a quarter of an hour the ozonised oxygen was perfectly perceptible at the other extremity. The paper was then withdrawn.

3. This same sheet thus treated was employed after the manner of the solarised papers of M. Niépce de Saint Victor, and in every respect produced the same effects. The other half sheet kept for comparison produced no effect.

4. A nitrate or chloride of silver paper treated with ozone on the contrary gave no perceptible result.

5. Ordinary paper ozonized possessed in every way all the other properties of solarised papers.

6. An ozonized paper kept for some time in a test tube gave out an odour which was not that of ozone but of an essential matter; it was, moreover, transfusible.

What can we conclude from this (asks M. Thenard), but that the phenomena of insolation (solarisation), described by M. Niépce, are chemical phenomena, determined directly by light, which acts only as an intermediate agent?

THE DRY PLATE.*

By Dr. J. Milton Sanders.

Having devoted considerable attention to the production of dry collodion plates, I thought that perhaps my experience might be acceptable. Now there have been volumes written upon the subject of the dry plate, the literature of which is quite as dry as the plates. After an experience of several months, during which time I have made several experiments upon this especial subject, I have at least convinced *myself* that all "preservative fluids" are wholly superfluous. The surface of the plate prepared in the manner I shall indicate is quite as sensitive, if not much more so, than any of those covered with the preservative fluid, so profusely recommended of late, especially by our brethren over the Atlantic. Besides this, at least one half of the trouble is dispensed with. To prepare the proper kind of collodion for the plates, all that is neces-

* Read before the American Photographical Society at the June Session, and extracted from *The American Journal of Photography*.

sary is to observe the following directions:—the pyroxyline should be of the most negative kind, that is, made at the maximum of temperature. The collodion should be the *alcoholic*—that is, containing three parts of alcohol (pure and of 98 per cent.) to one of ether.* And, finally, the collodion should be much thinner than the ordinary kind—say about four grains of cotton to the ounce. The process is simple, and so very like the usual one for real negatives, that any person competent to make the latter will find no difficulty in producing those in question. Pour the collodion on the plate, and sensitise in a forty-grain bath, slightly acidified with acetic acid, in the usual way. As soon as the plate is lifted out of the bath, wash it thoroughly in pure water. I cannot lay too much stress upon this process of washing; for, if not *thoroughly* done, a failure is the inevitable consequence. The plate should now be placed away in the dark to dry, and if the moisture of the place is not unusually great, they will keep thus for any length of time.† At least I have kept them for several weeks, at the termination of which time they were quite as sensitive as when first made. With this article, I send an impression printed from one of these dry plates twenty days after it was prepared and dried. When it is desired to take a picture, expose your plate about the same time your camera required for a wet plate. As soon as you are ready to develop, put your plate for *not over two seconds* in your bath, and then develop with the usual iron developer, as far as the reduction can be pushed. Wash your plate thoroughly, and fix in the hypo. bath. The two conditions necessary to insure success in the manipulation are: first, that the plate showed be washed thoroughly before it is observed to dry; and secondly, that it should have nitrate of silver restored to the surface before development.

These plates are generally sufficiently intense to print fine clear positives, but if not, then I find that they must be intensified by the following:—If the negative requires but little intensifying, it is best done by flowing over it a saturated solution of the sulphide of potassium. If, however, the negative should prove thin and require a considerable deposit of silver, the best plan is to observe the following:—In one drachm of acetic acid, No. 8, dissolve one grain of pyrogallic acid. Then add seven drachms of pure water, and a few drops of the bath solution. This should be flowed on and off the plate repeatedly until the desired intensity is obtained. The reason why I do not develop with pyrogallic acid is because it renders the film so rotten that the utmost nicety of manipulation is necessary to keep it on the plate. In fact, I think that while protosulphate of iron preserves the film hard and tough, it gives a more pleasing and satisfactory picture. The negative may be fixed with the cyanide of potassium, but this is not so good as the hyposulphite of soda. Besides the iron salt develops so speedily that an impatient operator like myself gets through the process without the evolution of any explative which may endanger his immortal soul! Although this process may be pronounced far from being original, still the multitude of preservative fluid processes which encumber the photographic journals suggest the suspicion that, as simple as this process is, it is but little known.

In conclusion, I need only remark that I have carefully repeated all the preservative fluid processes I could gain access to, and that I have found them all inferior to the one I have indicated. In another paper I shall give some important details upon the subject of "raising pictures" by the use of Mr. Seely's megascopic camera.

Mr. Seely remarked that he did not endorse the main conclusion of the doctor, that there was no need of other processes than the one given. The theory of dry collodion is not well understood, indeed, experimenters seemed to have gone on without theory—therefore without chart or guide. At some length he advocated the theory, that the presence of organic matter capable of decomposing silver salts or forming compounds with them was necessary to the production of a photographic image, and that gun-cotton or the dried film was not such a substance; and that therefore such a substance must be added to the bath, collodion, or film. On such a theory this added substance is in no proper sense a preservative. The wet collodion answers the condition required by the theory, but the organic substance contained is volatile, and when the film is washed and quite dry, nothing is left but inert gun-cotton film and the silver salts. Dr. Sanders's means is undoubted, as he sends the society specimens of the work, but did he not use an old collodion or an old bath?

* This collodion should be sensitised, by adding to each ounce, five grains of iodide of ammonium or cadmium, and one grain of the bromide of cadmium; shake till the salts are dissolved.

† The best method of procuring these plates entirely free from hygroscopic moisture, is to place them in a tight box containing chloride of calcian. By this means sensitised paper may be preserved for any length of time without losing its whiteness.

STEREOGRAPHS.

Illustration of East Indian Scenery, by Capt. A. N. Scott, *Madras Artillery.*

Three or four months back we were favoured by Captain Scott with a few specimens of his photographic labour in the form of half-a-dozen stereographs of some of the more remarkable native Indian Tombs: since that period this gentleman has determined to publish a series, and we have recently received through Mr. Bolton, of Holborn Bars, London, whom we are given to understand has been selected to act as agent for their publication, a further instalment.

Every experienced photographer is well aware of the difficulties arising from having to operate in very hot weather—not only from the physical causes entailing an unusual degree of lassitude and fatigue in the artist, but also from the usual unruly behaviour of the chemicals employed, which, under such circumstances, often appear to cast off all control. If we add to these the annoyances arising from materials of doubtful quality, and the necessity, not unfrequently entailed, of having to substitute one substance for another (such as citric for acetic acid, for instance, or even lemon juice for either), in consequence of the ordinary supply having been exhausted with no means of replenishing the stock without a fatal delay, it will be readily understood how an unusual amount of energy and skill is requisite to the production of even mediocre results; and no small credit is due to the perseverance to which we are indebted for the specimens now before us. For the reasons assigned, it would be absurd to criticise results obtained under such circumstances as we have been describing by the same rules that we should apply to ordinary photographs; but we may remark that, even under this aspect, they are as creditable as the general run of those published, while as regards the interest and instructive character of the subjects depicted, they are immeasurably superior. Of these we notice especially a group of three of the native princes, with their attendants, viz., *Nawaub Shumsh-ool-Oomra*, of Hyderabad, an old man, supporting his now listless frame by his arm over the shoulders of his son, the *Nawaub Iktidar-ool-Moolk*, seated on his right hand; the *Nawaub Tegh-Jung*, the grandson, a larger and taller man than either of his progenitors, being seated bolt upright in a constrained and rigid attitude, forming a marked contrast to that of the other two. The oriental costume, with jewels and flowing robes, it must be confessed, gives a very effeminate aspect to the wearers; and this is not a little enhanced by the display of certain gossamer-like muslin under-garments protruding from beneath the robes, and which bear a marvellous resemblance to ladies' petticoats. It is, however, a truly interesting and characteristic group.

Another similar group to the last named, but not quite so well executed, partly owing to a slight movement of the sitters, consists of the *Nawaub Salar Jung*, minister at Hyderabad, with a nephew on his left, and the *Rajah Narrindhur* on his right hand.

A very highly interesting specimen of the series is one representing the *Interior of the Summer Residence* of the Nawaub Shumsh-ool-Oomra, whose portrait we noticed above. This consists of an extensive quadrangle, open above to the sky, and surrounded on all sides by a colonnade, with the peculiar crenated arches prevalent in eastern edifices. A large reservoir of water nearly fills the open part of the quadrangle, and the centre is occupied by an elegantly-constructed fountain, which bears, however, strong evidence of being of European manufacture. The leaves of numerous aquatic plants are seen floating on the surface of the water; and around the reservoir are placed pots containing plants, and the curiously quaint seats, all of China, and with the appearance of which we have of late become pretty familiar. Under the colonnades are dependent numerous small chandeliers; and in front of them are blinds which can be lowered so as to protect any part exposed to the sun, the whole appearance being somewhat similar to that presented by the Alhambra Court in the Crystal Palace.

The *Tomb of a Mahomedan Lady* at Booran Sahib's Durga, near Hyderabad, looks far more like a palatial residence than a tomb, and gives an excellent idea of the style of these extraordinary edifices.

The *Hill Fort of Golconda*, as seen from the tombs through one of the arches, is excellent as a stereoscopic subject.

The *Tomb of Abdoola Shah* presents more the aspect of a temple, while, as a contrast, the *Mahomedan Tomb*, near Hyderabad, is altogether different and simpler, being composed chiefly of a light kind of trellis-work, and is picturesquely overshadowed by a fine specimen of the banian tree.

Although far inferior to the others in a photographic point of view, the *Elephants with Heavy Ordnance* will no doubt attract

much attention, as, to European eyes, the sight of two of these huge animals harnessed, tandem-fashion, to a heavy gun, presents a decided novelty.

We have little doubt that this series will become a highly popular one.

Letters to a Photographic Friend.

No. II.

MY DEAR FRANK,

THE first name I had upon my list was that of Melhuish; for as this well-known photographer has lately entered into partnership with McLean, the print publisher, of the Haymarket, this was the first establishment that presented itself in progressing westward. I found that Mr. Melhuish had as yet found no occasion to alter the plan of his metal camera, a description of which you will recollect was given in the 1st January number of THE BRITISH JOURNAL OF PHOTOGRAPHY; but he had found it impracticable to employ aluminium in its construction, that being, with our present knowledge of its properties, a very unworkable metal. My attention was then given to an examination of "MELHUISH'S UNIVERSAL OBJECTIVE," a lens lately introduced to the notice of photographers. This consists of a front and back lens of ordinary construction (excepting that the back is a little larger than the front combination, so as to include a larger angle and admit an equal amount of illumination over the entire field), together with a small extra achromatic cemented combination placed midway between them. The front and middle lens screw into the same tube, to which also *the shade* is attached. This tube slides into *the outer mounting* that carries the back lens, which again screws into *the flange* attached to the camera. By arranging these three lenses in different ways, each sized "objective" is capable of placing three different portrait combinations and a landscape lens at the disposal of the photographer, and this in the space of an ordinary portrait combination of the same capacity. I need hardly say that this is a great boon to the travelling amateur, especially when I tell you that the performance of the various combinations is very good, and the price of these "objectives" very moderate. I will endeavour to give an idea of their arrangements by describing the half-plate size.

COMBINATION No. 1 consists of the front and the back lenses, with the extra lens between them: this gives a focus of four and three-quarter inches (measuring from the back lens), and pictures four and a-quarter by three and a-quarter, and is then applicable for stereoscopic work. On fitting diaphragms over the back of the middle lens the arrangement is then suited for copying and enlarging.

COMBINATION No. 2 is produced by drawing out the inner tube, unscrewing the diaphragm and extra lens. On replacing the tube, the arrangement consists of the back and front lens: this gives a focus of six inches, and pictures six and a-half by four and three-quarters. This combination in the objective experimented on was very rapid in action.

COMBINATION No. 3 is produced by unscrewing the entire combination from *the flange*, removing *the shade* from the front lens, withdrawing the tube and front lens from *the outer mounting*, and screwing on the extra lens to the end of the tube; the front lens is then reversed in position and screwed into *the flange*, so that it becomes the back combination, and the extra lens the front one. As, however, a shade is necessary, the original back lens is removed from *the outer mounting*, and put aside, *the shade* is then screwed on to the part of the mounting that originally screwed into *the flange*, and in a reversed position, *the outer mounting* is slipped over the tube that carries portrait combination 3. This arrangement gives a long focus of nine or ten inches, and portraits eight and a-half by six and a-half. With a diaphragm it may also be used for landscapes or copying.

COMBINATION No. 4 consists of the front lens *only* screwed into *the flange*, with its tube projecting forward, and a suitable sized diaphragm screwed on to the end of it, over which a small cap slides to exclude light; the other lenses and mounting being put aside. This gives a focus of fourteen inches, and landscapes ten by eight, free from distortion, and possessing great definition.

Combinations 1 and 2 may be finely adjusted by means of a rack and pinion with a double head, so that they may be focussed from either side of the camera.

The diaphragms are readily applied, changed, or removed, as it is only necessary to pull out the inner tube to screw or unscrew them; and, as no slot is introduced into the mounting, it is in no way weakened.

In each of the four combinations the chemical and visual foci are coincident; and after examining four negatives taken respectively by Nos. 1, 2, 3, and 4 combinations of the half-plate objective, I have formed a very favourable opinion of their action, though, as you know, I have hitherto been rather prejudiced against *multum in parvo* combinations, and have preferred being encumbered with separate lenses for special requirements; but I think these new lenses of Mr. Melhuish may fairly be considered cheap and good. Six different sizes have been produced, varying from the quarter-plate up to six inches in diameter, for the back lens.

Mr. Melhuish showed me a first attempt at an extension to cameras of large size of his principle of employing metal. The model was made to a half-plate size, and consisted of a brass frame 10½ wide by 8¼ inches high, and 3⅝ inches deep: into this space, three dark metal slides, the focussing glass, a bellows body, and the base-board are packed. When in use, the metal frame is clamped by nuts on to the base board, which is framed on a telescopic arrangement, and carries a hinged support for the front of the bellows and the flange plate of the lens; this allows a range of focus from two to sixteen inches, the extension being effected by means of an endless screw, which also acts the part of a fine adjustment for the lens. The body is capable of being coarsely adjusted by an arrangement independent of the endless screw. This is a very light, compact, and efficient form of camera.

On leaving Melhuish's, I bent my steps to Thomas's, in Pall Mall; but, finding that he had nothing absolutely novel to introduce to my notice, I made my way to Murray and Heath's, in Piccadilly. [Here I may state, *en passant*, that if, in journeying from west to east, I apparently overlook any well-known photographic house, you may take it for granted that the proprietors have not called my attention to apparatus that comes under the head of *Novelties*, but are satisfied as to the efficiency of their existing models]. My attention was first given to a whole-plate portable bellows camera, of great rigidity. This instrument packs into a thickness of six inches, and when open gives a range from four and three-quarter inches to sixteen inches, for lenses of different focus. The base-board is hinged, and turns up behind the back when packed, but when lowered for use, is secured, with great firmness, by means of a short brass bar, attached by a pin (on which it rotates) to one side of the hinge-plates, fitted on each side of the camera: this bar fits over four pins, two on each side of the hinge, and is then clamped by means of a screw to the opposite side of the hinge-plate, so that it renders the hinge nearly as solid as if it were cast in one piece. This you will better understand by referring to the sketch below.

FIG. 1.

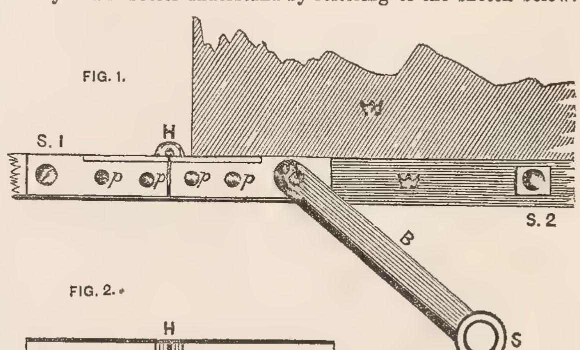

FIG. 2.

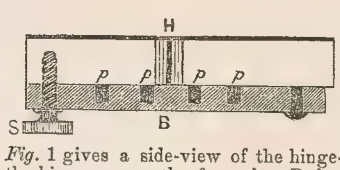

Fig. 1 gives a side-view of the hinge-plate and camera, H being the hinge, *p p p p* the four pins, B the bar that fits over them, S the head of the male screw that clamps into S 1; W W is the woodwork of the base-board and side of the camera. *Fig.* 2 gives a top view of the hinge-plate, with the bar clamped tight over the pins, the reference letters corresponding with those in *fig.* 1.

When the camera is packed the bar B turns back out of the way by being screwed into S 2, *fig.* 1. This screw and all others that are usually loose, in this camera are made so that they cannot be separated from their fittings, their loss on the field being thus prevented. The above contrivance renders the base-board so rigid

that the objection hitherto raised to this kind of folding arrangement is no longer tenable.

When the proper focus is obtained, the back is clamped by a nut placed *within* the camera: this method allows the back to be drawn *quite* to the end of the base-board, and thus saves about two inches in its available length, which would, in the ordinary way, be occupied by the brass clamping piece and the wood beyond the slot. As a rule, Messrs. Murray and Heath make all their cameras *square:* this allows the plate carriers to be placed with their greatest length either in a horizontal or vertical position. I am surprised that a plan so obviously convenient has not been universally adopted; for, although it is not by any means novel, it is an arrangement that has, as far as I have seen, been too much overlooked by camera makers of late years.

The focussing glass fits inside the camera, when packed, and the plate frames, instead of sliding down a groove the entire height of the instrument, as is usual, fit upon beads and grooves, an inch in height, placed at the top and bottom corners of the back, so that the frames have only a play of about an inch before they are in position: the greater the size of the camera, the greater will the convenience of this arrangement be found. The front slides in *a vertical* direction only, for the adjustment of the foreground; but if to this were added a horizontal motion, with a suitable plate-holder, the instrument might be employed for taking stereoscopic views with a single lens, which its short range, when shut close, would admit of (four and three-quarter inches), and the camera would then be of universal applicability on a tour. I likewise saw a camera for plates eighteen by sixteen, constructed on the same principle, which was very little, if any, thicker than the one I have described to you. I also examined a stereoscopic camera constructed on the principle of the one fitted up for Prince Alfred, by Messrs. Murray and Heath, which is an extremely convenient arrangement for amateurs; but as this has been well described in the Leader of number 119 of The British Journal of Photography, you will already have become acquainted with its design, and I will not, therefore, waste time or paper in rediscussing its merits. The double slides for dry plates sold with this and their other forms of twin lens cameras are beautifully made: they open like a book for the insertion of the two glasses, and have a hinged metal plate inside to insulate one from the other during exposure. Messrs. Murray and Heath have given great attention to the perfection of their legs (of course I do not refer to their lower extremities, but to the legs of their tripod stands); and by an ingenious construction of the hinge, and an overlapping of the wood at the point at which the limbs fold, they have secured a portable stand of great solidity, to which it is almost impossible to impart tremor.

For each sized camera they have arranged a very convenient "field box," containing twelve plates, which, with all necessary chemicals and appliances, packs into a small space.

The clamp that they employ for holding glasses during the operation of cleaning is adaptable to plates of any size, by means of an endless screw. They have also an oblong levelling stand, with pins on its upper surface for supporting four stereoscopic plates at one time, when preparing or developing them by any of the dry processes. Their pneumatic plate-holder has also an improvement on the ordinary motion for producing the vacuum; and when employed for glasses of large size, is attached to an arm, so as to give greater freedom of motion to the operator. Their collodion pourer, which is very long in proportion to its length, to allow any sediment to settle, has an inner-lipped funnel-shaped neck, capped like a spirit lamp, so that, being constantly surrounded by an atmosphere of ether and spirit, it is kept free from those hard incrustations that give rise to imperfections in the film common to the ordinary forms of this instrument: it is graduated up the side. Their glass dishes for sensitising paper are very nicely cast, so as to present rounded corners, with a very flat and even bottom; they are one inch deep; the edges are grooved, to allow a sheet of glass being accurately fitted on the top to exclude dust, and are protected by an outer pinewood case, with pads of stout felt at the angles. The last contrivance I gave my attention to at this establishment was a frame for printing transparent positive stereographs from negatives taken in the twin-lens camera. The frame is double the length of a stereoscopic plate; the negative is inserted in a cell in the centre of it; the dry plate to be printed is placed at one end of the frame, so that the right-hand end covers the left-hand picture of the negative; the back is then closed down, and that half of the plate exposed for a few seconds to diffused light; the frame is then taken into the dark room, and the dry plate removed to the other end of the frame, so that the left side of the film covers the right-hand picture of the negative; it is then exposed for the same time as the other half. This arrangement avoids the necessity of cutting the negative in half, for the purpose of reversing the position of the two pictures, and is well adapted for amateurs who may wish to print their own transparent slides; but it would not be suited for professional use, as it occupies too much time in manipulating.

I must not forget to call your attention to Mr. Smartt's tent, which, although invented in the early part of 1858, has only just been brought to its utmost point of perfection. The peculiarity of its construction is, that its framework when put together constitutes a system of triangles disposed so as to strengthen and support each other. The following sketch will convey a better idea of its arrangement than any lengthened description I can give.

Over this framework a carefully contrived covering of a double thickness of black twill is fitted in such a way that the overlapping folds at the entrance readily adjust themselves to each other to the perfect exclusion of light. This tent is both roomy and airy; and by the various contrivances for economising the available table space, affords the greatest comfort in manipulating plates, even of the largest size, the internal dimensions being three feet square by six feet high. Both the table and developing tray are contrived so as to fold up into an exceedingly small space when out of use. The weight of the whole, when packed in the case, is twenty pounds, and the tent is easily erected and taken down by one person. If I say it is decidedly the most practical and convenient tent yet introduced, I think I am borne out in my opinion by the fact that it is not only employed by such well-known photographers as Fenton, Bedford, Raven, and others, but by Negretti and Zambra, (themselves photographic apparatus manufacturers), who have sent two or three of them to their operators in China and Japan. The late Astronomical Expedition to Spain likewise took out one of these tents.

From Piccadilly I turned into New Bond Street, and called at Callaghan's, Voigtlænder's London agent, to examine the orthoscopic lenses made expressly for taking stereographs; but as they had neither negatives, prints, or camera, wherewith to test the capability of the lenses, I was not enabled to form the slightest idea as to their performance. I can only tell you that they consist of two achromatics of $\frac{5}{8}$ and $\frac{11}{12}$ inch, with a combined focus of four and a-half inches, and that they cost three pounds, seven shillings, and sixpence. Voigtlænder now makes his lenses with the visual and

chemical foci coincident. I do not know whether you are aware that the ordinary orthoscopic lenses (small size) are suited for taking stereoscopic portraits; but, when worked in pairs, they answer admirably for that purpose.

At this point I thought it time to bring my first day's jaunt to a close, so I turned my steps hotelwards, and, after refreshing the inner man, I devoted my evening to this letter, that your inquisitive mind might have its ravening satisfied with the scraps of photographic fodder I had been able to pick up.

So believe me,

Yours faithfully,

SIMEON HEADSMAN.

P. S.—I have just seen that you have handed over my first epistle to The British Journal of Photography, but I find that that wretched printer's devil has misinterpreted my MS., and broken the sequence, after the line—"But never a one to keep:" it should read—"if one is to believe the pathological investigations that have lately occupied attention," &c. As the passage stands, it does not render my meaning.—S. H.

New Collodion Process.—*By M. Poitevin.*—Take an ordinary iodised collodion containing an excess of alcohol. Before coating the plate add one part of nitrate of silver to fifty parts of the collodion. Pour on the coated plate a solution of iodide of potassium of the strength of two or three per cent., to which has been added iodide of silver. Wash the plate in plenty of water and leave it to dry. An insensible film of iodide of silver is formed on the surface of the plate. When it is desired to operate, sensitise the plate by pouring over its surface an ordinary bath solution of nitrate of silver, and then expose it in the camera. This process enables the operator to dispense with the dipping bath, a small bottle of bath solution being substituted in field work.

Meetings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

FIRST OUT-OF-DOOR MEETING.

In the month of July, on its twenty-first day, in this summerless year 1860, the South London Photographic Society held—well, I suppose it *may* be said to have held—its first out-door meeting. Those who recall the leaden sky, steadily persevering rain, and damp, cheerless, wet-blanket-like feelings engendered by the day in question, will not wonder that the attendance was —hem!—*not* very large, although, as is usual with small audiences when they appear in print, it was, of course, "very select."

I promised a report of this meeting because it was a photographic experiment in the success of which many might be interested; but whether it will *now* prove worthy of insertion in our much-valued organ or not is for you, dear Mr. Editor, to decide. Perhaps I had better make it a personal narrative.

As Secretary, then, I was in a position to know that most of our members *intended* to be present; for I had heard of new cameras then first to be tested—of new modifications in existing processes then to be practised—and I had received the names of new members desirous of joining our new Society by being elected in this new manner, for the express purpose of being present at meetings so new in their character. Preparations had been actively made by our most successful operators; and sanguine hopes were entertained by us all of a glorious introduction to the out-door practical and experimental meetings of the South London Photographic Society. But, alas! "who can rule the uncertain chance" of weather? The morning came—so did the rain! The only process likely to be practised was "the wet process," and our "time of exposure" was evidently ill chosen. A new "preservative" medium might, I thought, answer, if composed of a thin waterproof coating and stout shoe leather—but who would try it? As the hour at which the train started drew near, I fancied the mournful-hued-cloud panoply appeared somewhat more transparent: hope whispered it *may* be fine, and conscience said, *you* at anyrate ought to be there. So I started off. On my way to the railway station I called upon a friend and member who had purposed going, but could not induce him to accompany me to what he called "the regions of wet green sponge and watery mud." With him, too, stayed away a party of three; but from him I took one, who, when I enquired if he had taken lunch, replied, "Yes, I have taken two whole-plate negatives, a quarter-plate positive, and———" "What a queer lunch!" interrupted I; upon which he explained that he had taken these *and* lunch in a certain short time. As we were rather late I hailed an omnibus, which in the course of ten minutes conveyed us from King William Street, by jerks, into Gracechurch Street, and there stopped. I looked at my watch. There was not a moment to spare; but what could be done? The omnibus was securely packed in a dense mass of motionless vehicles, and there was "a block in the city." So there, on that miserable "knife-board," sat we twain, listening to sarcastic Jehus, whose taunts and jeers re-echoed far and near. One driver, in an unusually large white hat, intimated, with a grimace, by pulling his waistcoat outward, that there was a vacancy within in consequence of delayed dinner; whereupon another "whip" suggested that his dinner might have got into his hat. The combination of the words "now then!" seemed to possess peculiar power in giving force to a variety of loud exclamations, such as "keep moving!"—"where are you going to?"—"hold hard!"—"don't be in a hurry!" Escaping at length from this din and confusion we reached Shoreditch Station, exactly in time to lose our train. There was, however, another, going to Stratford, and into it we jumped, resolving to walk on to the Eagle, at Snaresbrook, our appointed rendezvous. In the train we fraternised with a worthy old gentleman, eloquent in praise of rifle volunteers; and reaching our destination, found the sky of a still lighter grey, and the clouds on the move. Good signs for hope! A fresh summer breeze saluted us as we got into the free country road, and anon specks of sweet, sweet blue peeped smilingly out from the wide outspread veil of monotonous grey. On we gaily trudged. The sunshine streamed through the breaking clouds at last, and the rain drops, which but now were full of cheerless images, became redolent of suggestive beauty, being no longer the clothes-soaking, mud-making, nasty, wet things they were, but flashing gems, glorious brilliants, diamond drops glittering on the foliage of tree and hedge, like the fabled fruit in Aladin's magic cavern. We had not brought our cameras, thinking the chance of using them too small to warrant (for we patronise the "heavy wet," not the malt process) the trouble of conveying apparatus; but now how we regretted it! The beautiful "bits," the charming effects of light and shade, &c., seemed to assume new beauty, as if to mock our helplessness. Here a group of elegant ferns, looking as if nature, with an artist's touch, had "*composed*" them expressly for a picture, defied us to photograph them; and there a mighty elm tree over-hanging, as if with the graceful beauty of protecting love, a neat little specimen of rustic architecture, coming out from the dark green background in a gleam of sunny light, made us almost think of rushing back to town for our cameras. But for all this, we were *very* jolly, and pitied the friends who were not with us very much indeed. I proposed "leap frog," but my friend had objections. We must have looked as merry as we felt though, for sundry rustic maidens "*couldn't* help" smiling as they passed, and, having smiled, tried, of course, to look unnaturally solemn as soon as they perceived us looking (my friend is married, so pray don't mention this again). Then my companion described a picture he had taken of "the eclipse," which represented a comically earnest youth, watch in hand, staring through a piece of smoked glass, which he had unconciously pressed against his nose, thus securing an unmistakable image of "the point of contact." And so, chatting, joking, and laughing, we reached the "Eagle" aforesaid.

Alas! we found no one there — no, not one! After certain refreshing draughts, we started towards the railway station, and we met "a member." Looking down one of the pretty green lanes—oh! joy!—we saw on its three thin tall legs — *a camera!* Starting at the run towards it, we spied another!

"There's Hannaford!" cried I.

"There's Howard!" cried my friend.

And, truly, there *was* Hannaford, with a few others; but, sadly, there was *not* Howard, but some one whose figure resembled that of our excellent Treasurer's.

Well—for I must not be too long in recording a failure—the afternoon was a glorious one; the sun was fairly out; and the colossal clouds, like mountain masses of sun-illumined snow, melted in their silent majesty from the clear blue zenith. I longed to photograph them, for it was just the sky for the purpose. The "uncultured flowers of the wild," with the tears of heaven in their fragile cups, filled the air with sweet odours; and several bouquets of these wild beauties were gathered for the two ladies, who alone of the many we expected had armed themselves — prudently — with umbrellas, and bravely ventured forth. Of course we met "the gipsy," who was most intensely anxious to enlighten her "merry" gentlemen and "pretty" ladies upon the fortunes the future had in store for them, and by whom I was informed—gratis—that for all I had been "so unsettled" I should "settle down," &c., &c., &c., but who was, nevertheless, strangely bound by some mysterious, and doubtless *very* terrible bond, never to tell an *entire* "fortune" for nothing.

The gipsy was succeeded by a timid, bashful beggar girl — yes, a *real* beggar girl *really* bashful! (there's a novelty for you!) — who stood afar off, and in a quiet little way asked us to give her "a ha-penny." She was a little, chubby, brown-faced child, picturesquely rough about the head—not at all communicative, and prettily bashful, just as an ordinary timid child might be; by no means one of your whining, cunning, hungrily-eager town beggars, but evidently one new to her pitiful trade, and, happily, all unconscious, as yet, of its degrading character and influence. God help her out of it, and that, too, speedily!

A number of dry plates were exposed; but the light changed so rapidly that a scene beautiful when you took the cap from your lens became gloomy and dull not many seconds after, in consequence of the way in which that laughingly mischievous old Sol played "bo-peep" with the passing clouds. Wet collodion would have secured such effects before they could have fled. The great drawback, however, was motion in the

foliage, which really seemed to enjoy a quietly laughing whisper at the way in which it baffled our efforts; and this, perhaps, would have proved even a greater enemy to success with wet than dry plates.

I did hope I should have had to chronicle matters of more importance than the foregoing trivialities, as I fear you may think them; but, have patience, and next month I may do better. Without detaining you much longer I will add that, although this our first out-door meeting has been undoubtedly a failure, purely in consequence of the weather, it certainly goes to prove that no party of what is called "pleasure" can so truly deserve its name as one possessing that community of feeling and purpose rarely to be met with in a promiscuously selected company, got together with very little reference to tastes or pursuits; for, even under the unpromising circumstances described, we contrived to be very much amused, interested, and pleased.

The August meeting will be held *(weather permitting)* on the third Saturday of the month, on Hampstead Heath. Members to meet under the Scotch Firs, at half-past two o'clock, p.m.

A Photographic Pic-nic, to be composed of members and their friends, having been proposed, those who may be desirous of joining the party will please to intimate the same to me at their earliest convenience.

A. H. WALL, HON. SEC.

FRENCH PHOTOGRAPHIC SOCIETY.

AN ordinary meeting of the Society was held on June 15th, M. Regnault (of the Institute), President, in the chair.

M. Champion was ballotted for, and duly elected a member.

M. THOURET presented to the Society three positive proofs, one being the reproduction of a sketch, the two others of engravings.

M. MAULEZ called particular attention to the remarkable tone of these prints.

M. EDOUARD DELESSERT presented to the Society two positive prints of very considerable dimensions (about thirty-two inches by twenty), produced direct by enlargement from the little negatives taken for the purpose of printing the so-called *carte de visite*. These two proofs excited considerable interest amongst the members present at the meeting, as they presented the remarkable feature that each print was made up from two separate sheets, with the lines in perfect juxtaposition by means of pasting the two edges of the paper together.* M. Edouard Delessert conquered the difficulties presented in the manipulation of proofs of such large dimensions thus:—the three sheets being salted, sensitised, &c., in the same baths, and under exactly the same conditions, do not present any difference under the action of light, or in the fixing and toning baths; consequently the design possesses exactly the same tone and the same tint over its entire surface.

The thanks of the Society were voted to M. E. Delessert for his gift.

M. BERTSCH presented to the Society a proof, twenty-six inches by seventeen inches, obtained by enlargement from a negative two inches by one and one-third of an inch; and on the invitation of M. Regnault, he gave, as *á propos* to this proof, a very perspicuous explanation of his method of procedure in obtaining the same. [See page 217].

At the conclusion of M. Bertsch's communication, the PRESIDENT begged to observe with regard to it, that M. Civiale, jun., had already forestalled him (M. Bertsch) in the construction of a camera of small dimensions. This camera, specially destined for the taking of views for military reconnoiterings, is of such simplicity that it may safely be put into the hands of persons possessing very little knowledge of the photographic art.

With regard to the difficulty in the obtainment of positives by enlargement, mentioned by M. Bertsch, he begged to add that, without doubt, it would be necessary to make use of the heliostat in order to obtain good results; but that if the construction of heliostats of dimensions as large as the enlarging apparatus will require is rather unusual, it may, nevertheless, be simplified, thanks to the particular circumstances in which the operator finds himself. In fact, in this case the rays reflected by the mirror need not be horizontal; and it would, moreover, be easy to place, on the outside of the apparatus, a pendulum, vibrating seconds, so that the construction of the heliostat would be greatly simplified, and we might easily give it large dimensions.

In conclusion, he expatiated on the correctness of the observations made by M. Bertsch, respecting the use of lenses of long focus for landscapes. Photographers, in fact, when making use of the latter, always make a mistake by putting the horizon in focus, whilst, on the contrary, the focussing should be made on the foreground only. He reminded the meeting that he had several times already called their attention to this mistake, which is of the greatest importance in the consideration of the aërial perspective.

The thanks of the Society were given to M. Bertsch for his donation.

MM. DAVANNE and GIRARD laid before the Society a negative obtained on the day of the meeting, on a sheet of dry waxed-paper, sensitised a year previously, and preserved during that period in one of M. Marion's preservative cases. The negative presented some defects, and did not quite possess all the freshness of one obtained on paper recently prepared; but it proved, nevertheless, that within certain limits negative paper so preserved retains its sensibility.

M. HUMBERT DE MOLARD asserted that he had obtained negatives of good quality on dry waxed-paper, preserved for five or six months in the same way.

The Society thanked MM. Davanne and Girard for their communication.

MM. DAVANNE and GIRARD communicated to the Society a continuation of their *General Study of Positive Prints.*

The Society thanked the authors for their communication, and ordered its insertion in the *Bulletin.*

M. GIRARD called the attention of the members to specimens of photozincography, produced in England by Colonel James, and published in an English Journal: one is a reproduction of an engraving, the other is from a photographic reduction of a military plan. M. Girard remarked that great interest was attached to this novel application to topography, which had already attracted the attention of the Society.

The Abbé MOIGNO observed that the process followed by Colonel James appeared to be exactly the same as that which had been published some time since by M. Poitevin, and he regretted that the English operators had not thought fit to give the name of the inventor.

M. PRETSCH forwarded to the Society a certain number of proofs printed typographically, according to the process he had already described. These proofs were handed over to the commission for awarding the prize offered by the Duke de Luynes.

M. WULFF exhibited the apparatus of Mr. Moule for night photography, and, in the presence of the members, obtained some collodion positives in twenty seconds.

M. HUMBERT DE MOLARD experimented with another composition which gave a somewhat whiter flame than that first shown by M. Wulff, but which seemed to give identical results.

The PRESIDENT thanked Mr. Wulff in the name of the Society for the experiments executed before them.

The meeting was then adjourned.

* *From this expression of surprise on the part of the members of the Society, we infer that French photographers are as yet unacquainted with Mr. Rejlander's* "Two Ways of Life," *and the difficulties of manipulation mastered by that gentleman in uniting the lines at the edges of the sheets of paper employed in the production of the large edition of that celebrated composition, a description of which was given in this Journal for 15th April,* 1858, *and about the same time in the* Journal of the Photographic Society.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER VII. *(Continued.)*

DRAPERIES.

HAVING forwarded the background, it will be as well, before finishing the face, to do as much for the drapery. Now, here you have your main chance both for effecting a good arrangement of *chiaroscuro* and colour. In the treatment of this portion of your subject a great opportunity exists for the display of judgment and taste. Inelegant folds or breaks may, as I once before said, be lost in shadow, altered, or painted out; and any details which chance to be injurious to the general effect may also be rendered less conspicuous, or altogether removed. Folds which have value for their pictorial or descriptive qualities should be preserved with the most scrupulous care; but others, if of a superfluous character, and having a tendency to destroy the breadth, may be destroyed. (If necessary the printer can assist you in effecting the removal of folds too deeply marked to be readily concealed with your water-colours, but this will not often be the case). The more massive, graceful, and flowing your folds, the better their effect; but their character, as expressive of texture, must never be lost in attempting to secure such qualities.

Now, with regard to the colours of your draperies: these should not be a mere matter of imitation, but rather one of careful selection and thoughtful combination; therefore it is as well to obtain from your patron, where necessary, some latitude for your own taste and skill.

Please to lay down your brush awhile and go back to Chapter III., which was dedicated to the consideration of the principles of colouring, and then let me chat to you upon the subject for a short time longer.

You know what the key-note is to a musical composition, of course, and its importance in the realisation of harmony. Now just as important in regard to the same result, and of exactly the same character, is the key-tone of a composition of colours: that is to say, the tone given by some predominant colour to which all the others have a subordinate relation. Thus, supposing the key tone be orange, any colours you introduce will be duly made to harmonise with it: the purples by becoming warmer or more red, scarlets and yellows more or less orange, greens more yellow, blues of a warm grey tone, and, in short, all colours will be modified by the introduction of orange into the composition, either directly or indirectly, according to the peculiar qualities of the colours and pigments.

The harmonious effect thus obtained is preferable, I think, to the more brilliant result given by greater contrasts, or a more striking diversity and purity of colour. We find this repose and harmony characteristic of nearly all the works of nature, in the most beautiful of which we find the fewest unbroken or positive colours. Of course nature also presents us with harmonies of contrast as well as analogy; but the former are but few, very few, compared with the latter. Take, for instance, the beautiful colours flowing into and from each other in the rainbow, the clouds at sunrise or sunset, &c. In the best pictures of our greatest masters the primary colours are very sparingly employed. But do not mistake my meaning, and neglect the important principle of variety in colour; I merely wish to impress upon your mind the importance of connecting affinities. The harmonies of analogy and of contrast have, however, been touched on in a previous chapter, and therefore need detain us here no longer.

I have seen some charming results from the following colours judiciously combined in their proper proportions:—

White, pale sea green, and rose colour.
Light yellow, purple or violet, and blue.
Pale green or blue, yellowish white, and red.
Orange, purplish violet, and blue.
Pale green, purple, and pink, &c., &c.

In adopting the above arrangements remember that the proportion of cold colour should not be large, but only just sufficient to counterbalance the warm. You should calculate their (the colours') relative degrees of power (see Maxims 8 and 13), and may consult the geometrical rules which have been adduced by various experimentalists for this purpose;* for the present take the following as a guide:—Red is to green as 5 to 11, yellow to purple as 3 to 13 while blue and orange are generally considered as of very nearly, equal power (see the chapter on colours as pigments). You will discover that certain colours must be kept apart, such as purple from red, red or green from yellow, blue from green, purple from blue, and so on; and that too large a proportion of pure colours impart a very gaudy and inelegant appearance to your picture (see Maxim No. 14).

We come next to consider the effect our colours will have upon the flesh, to which they must all be primarily under subjection.

Of course you would never think of bringing pale blue in contact with a sallow skin, pink near a red face, or deep red near a pale one; because the pale blue would make the first more strikingly sallow; the pink cause the red face to appear more fiery than ever; and the deep red, by taking the very faintest tinge of pink from the pale pace, cause it to appear absolutely ghastly. On the contrary, you would keep neutral tints near the sallow face, to give its fresher hues the better chance of discovering themselves; you would bring a deeper red near the too ruddy face, to make it, by contrast, appear the paler; and, to give some delicate, fresh pink to the sickly skin, you would bring near it pale green.

If you place pale orange near a fair colourless face, it will make the poor thing look rather blue, because blue is the complimentary of orange; rose colour will destroy the delicate pink of a fair face; and a brown complexion will appear whiter when contrasted with dark colours. Referring to the excellent work of M. Chevreul, before noticed, I find that he considers the white, or Caucasian portion of our race, under two types:—

"The one with light hair and blue eyes,
The other with black hair and dark eyes."

Light hair he considers as being essentially the result of combined red, yellow, and brown; the two first colours giving it the character of a broken orange. The skin he also considers as representative of a pale orange, and its various hues sufficiently allied to the same to justify his assertion that the harmony of the whole is that of analogy.

Dark hair, associated with dark eyebrows, eyelashes, and eyes, contrasting with the white and rosy hues of the skin, he, on the contrary, considers as illustrative of the harmonies of contrast.

Now, we all know from experience how blue, the complimentary of orange, is always considered to accord well with fair complexions, and how the harmony of analogous hues best associate with the same. We also learn, from the same source, that the more powerful contrasts of colours are always *felt* to be more harmonious in connexion with the dark type.† Modifications of the types will of course suggest corresponding modifications of the associated colours; but the foregoing conclusions may form the basis of all your arrangements in reference to the colours of draperies, head dresses, &c., with reference to complexions.

* No work on the subject equals Chevreul's.

† "Yellow and orange-red, contrasting by colour and brilliancy with black, and their complimentaries, violet and blue green, in mixing with the tint of the hair, are far from producing a bad result."

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

A New Subscriber.—I can only refer you to the back numbers: the repetition of such information would be unfair.

Chromo (No. 2).—Changeable silks are most pleasingly effective when the lights and shadows are not of crudely contrasting colours. They have three colours, two distinct, and a third formed by their combination; but these again are liable to certain modifications from the effect of their polished surface, direct light, reflected lights, and shade.

Foreign Correspondence.

Paris, July 25, 1860.

On Friday, the 20th instant, the monthly meeting of the French Photographic Society was held under the presidency of Mons. Regnault, of the Institute. The meeting was numerous, and the animated conversations before the opening had for their principal topic a regrettable fact which is exciting general discontent. On behalf of Mons. Quinet, a seizure has been made, both at the artist's and at the manufacturer's of Woodward's solar camera, of apparatus with two or several objectives, and of stereoscopic pictures mounted as they usually are—that is, having the image protected on one side by the glass on which it is printed, and on the other by ground glass. Some years ago Mons. Quinet took out a patent, to which he has always been adding new clauses, so that it at present includes nearly everything which can be done in photography. For the most part these additions consist not in processes nor in arrangements of apparatus, but in ideas! And so he attacks, as infringing his patent rights, Woodward's solar camera, and all the instruments of the same kind which have been made, or which can be made, on the ground that he has patented the *idea* of the magnifying of photographic prints! In the same manner, because he has constructed a binocular camera, to which he has given the name of *Quinetoscope*, he opposes the manufacture and employment of any camera containing two or several objectives. I should never finish were I to enumerate all the inventions to which the said Sieur Quinet lays claim, seeing, I repeat, that he has comprised in his voluminous and elastic patent about all that can be done in photography. It is true that no doubt is entertained as to the issue of the affair before the tribunals; but it is not the less true that for several months the commercial interests of operators and makers, and the progress of the art itself, will have to suffer serious injury.

At the commencement of the meeting, Mons. Bertsch, who has incurred seizure, although he produced amplified prints with an apparatus invented by himself long before Mons. Quinet had the *idea* of so doing—Mons. Bretsch, I was saying, made a humorous allusion to the circumstance, and told us that, as he had been prevented from *amplifying*, he had *reduced*. In fact, he exhibited a small camera which he had just put together, and which was intended for the production of almost microscopic pictures. It is a brass box, the length of which from the centre of the objective to the other end is calculated in such a manner that the collodionised or albumenised glass is exactly in the chemical focus for objects placed at a distance greater than twenty paces. There is no ground-glass at the end of the box, since the point is taken beforehand, and is invariable. Upon the upper surface a water level and a quadrant index permit the operator to judge of the picture which will be represented by the photograph; for whatever is comprised within the limits of the quadrant index will be produced with fidelity upon the glass. To operate, it suffices to place the apparatus at twenty-five paces from the foreground which has been chosen. The glasses are about one-sixth the size of the whole plate. It is evident that, especially when albumenised glasses are used, this apparatus is the simplest and the most convenient that can be imagined. These images thus obtained are of the greatest delicacy. Seen with the microscope they present infinite details, for the mathematical exactness of the chemical focus takes away all indecision in the lines. These amplified with an apparatus such as Woodward's, for instance, give images of a beauty that is very near perfection.

At the same meeting, Mons. Bertsch presented two views taken by him during the eclipse of the 18th of July, in one of those rare moments when the clouds did not obscure the sun. The diminution of the solar light was sufficient to render the time of exposure

sensibly greater. With respect to the eclipse, there has been some talk of the results obtained by Mons. Foucault, one of the expedition sent into Spain to observe the phenomenon. It would appear, from what is said, that he was able to reproduce the red protuberances of the sun, but it is not known exactly to what extent his success goes. We hope that Mr. Warren De la Rue did not remain inactive, and we expect some views on the subject from England.

Mons. Lemercier sent to the Society several very satisfactory specimens of lithophotography. Most of the plates are obtained by means of two stones, as for chromolithography. Mons. Lemercier had sent with the specimens the photographic picture which had served as type, so that those present were enabled to judge, by comparison, of the degree of success obtained.

Mons. Colpaert, who forwarded a series of very interesting views of Peruvian edifices, landscapes, and negatives, communicated some useful information relative to the influence of climate upon photographic manipulation. During the summer the heat is so great in that part of the country in which Mons. Colpaert generally operates, that the cameras fall to pieces, the baths evaporate, and the collodion dries immediately. To obviate these inconveniences, the author of the communication applies, in the frame behind the collodionised glass, a piece of cloth, soaked in water. The inside of the apparatus is likewise lined with wet linen. His collodion, mixed with iodide of ammonium, is composed of seven grammes of pyroxyline, 450 of ether, and 500 of alcohol. He develops with protosulphate of iron.

Mons. Poitevin exhibited some vitrified carbon positive prints, from which excellent negatives may be taken by contact. This experiment is somewhat curious, but we do not think that its application has any great importance.

The letter in which Sir David Brewster spoke of the two drawings of Chiamonti existing in the Lille Museum, and presenting, according to the illustrious *savant*, the stereoscopic relief, has been reprinted in the *Lumière* and other special journals. We were all asking each other if the invention which so greatly honours Wheatstone and Brewster really dated from the sixteenth century?

Mr. Bingham, who has just returned from Lille, conceived the happy idea of reproducing the two designs in question to offer them to the Society. We all examined them with care, but no one detected in them the slightest difference. They appeared to all perfectly identical. In the stereoscope they are superposed, but without any effect of relief. For the present, then, we must be permitted to doubt that they were intended for the application Sir David attributes to them.

Lastly, Mr. Graham laid upon the table several cast-glass dishes, which are very convenient, especially for development, and of a very moderate price.

The meeting was enlivened by the perusal of a letter in which an amateur asked for the explanation of a singularity presented by a picture sent in with the request. It was the portrait of an officer, decorated with three crosses: the image, a very clear one, bore six crosses—that is, the three decorations had been produced twice, as if the chest, during the exposure, had made an upward or a downward movement. Yet, as I have already said, the rest of the picture was very clear. Was it an effect of reflection? or had the photographer, in recommencing the portrait upon the same glass, cleaned the latter insufficiently? The singularity caused much laughter, but found no explanation. I offer the case to your readers; may be, some of them will be able to satisfy the writer of the letter, and give him an answer to his riddle.

ERNEST LACAN.

REPORT OF THE SCOTCH COMMITTEE ON LENSES.

To the Editor.

Sir,—In your remarks at the last meeting of the London Society, you say that when the report on lenses was submitted to the Photographic Society of Scotland, you pointed out that the committee assumed to have discovered something extraordinary, viz., "that the position of the diaphragm in front of the lenses produced a barrel-shaped image of a square original, and the diaphragm behind produced the hour-glass shaped image." I am aware of only one report on lenses which was submitted to that Society; and as I have looked over it in vain for something to warrant, even in the slightest degree, such an extraordinary assertion on your part, I have to request that you will be good enough to point out any passage capable of being so construed.—I am, yours, &c.,

Edinburgh, July 10, 1860. J. T. TAYLOR.

[The preceding note reached us so shortly before the time of our "going to press" that we were unable to include it in our last.

We have to apologise for a statement made *in error* at the last meeting of the Photographic Society in our private capacity relative to the Report of the Lens Committee of the Photographic Society of Scotland, which Mr. Taylor correctly asserts contains, as we find on reference thereto, no such claim as that attributed to it, viz., the supposed *discovery* of the fact that the position of the diaphragm with reference to the lens affects the direction of the distortion, though an impression to that effect certainly existed in our mind. It is, however, true that we pointed out the fact above indicated as one well known at the time of the issuing of the said report, that being the object of our allusion to it. It is also quite true that we styled it a "droll" report—an epithet which, though not intended to convey offence, we should probably have abstained from employing had we had time for reflection. It must be evident to every one that in an impromptu discussion it is not possible for a speaker to weigh every word that he utters; and we can only regret having said that which has been regarded as obnoxious. Under these circumstances it is, perhaps, better not to enter into the reasons *why* the report appeared to us of the character designated, as we may be misunderstood as desiring to cast ridicule upon it—a desire which we certainly do not at all entertain. Suffice it to say that we objected rather to sins of omission than to sins of commission.—Ed.]

DE OMNIBUS REBUS.

To the Editor.

Sir,—1. The other day, when taking a photograph of a plan, I found I could not get the negative sufficiently intense to obtain a white ground in the print. Could you inform me of some method of remedying this?

2. Also, when a lens of a certain focus (say eight inches) is spoken of, what is meant? I have three lenses, and should like to be able to ascertain their focus, for the sake of calculation, &c.

3. Is there an alkaline gold toning bath that will keep any length of time?

4. What is the best book on chemistry to explain about photographic chemicals, &c.?

5. Some little time back, I had a box made, about three feet long and one foot square, and reversed my camera (a half-plate one), putting the negative in the place of the focussing screen, in imitation of the solar camera. I gave the paper (prepared by the calotype process) an exposure of twenty seconds, developed with gallic acid, and succeeded in getting a pretty good enlarged positive. This was in the ordinary diffused light, without a condenser or anything else. I am an amateur in the fascinating art, and should feel much obliged if you could give me any information on the above subjects.—I am, yours, &c., PHOTO.

Kensington, July 18, 1860.

[1. A collodion that has been some time iodised will generally give density enough, though the exposure required may be somewhat longer. Also, when developing, the addition of a small quantity of dilute albumen materially assists in obtaining a dense deposit.

2. A lens of eight inches focus means one that would have a distance of eight inches between it and the sharp image of the sun formed by refraction through it. This definition, however, only holds good for a thin single lens, say a spectacle glass. With a compound lens, the form and construction has much to do with the focus, under any given circumstances. (See the papers by Mr. Grubb, recently published in this Journal.) With a compound lens, its *equivalent* focus can be ascertained by comparing the size of an image of any given object formed by it with the image of the *same* object formed by a spectacle lens (the focus of which you can measure) at the same distance.

3. No.

4. Hardwich's *Manual of Photographic Chemistry*.

5. See an article by M. Bertsch, in the present number.—Ed.]

DRY PROCESS WANTED.

To the Editor.

Sir,—Lately I have been preparing my photographic plates by the collodio-albumen process; but I find that I cannot spare time enough to continue preparing and developing them in that laborious manner, and, consequently, I should feel much obliged by your informing me whether there is no process by which, firstly, I should lose less time in developing and preparing? and, secondly, whether I should have plates as sensitive, or more so, than by the collodio-albumen process, and which would keep undeteriorated during about a week?

Would the malt process, described in your last Journal, not be likely to suit me? If so, will malt, which cannot be got everywhere, keep good during any lengthened period of time?—I am, yours, &c.

C. A. G.

[We think you will do well to try a modification of Fothergill's process, employing about two grains of an alkaline citrate or phosphate in each ounce of dilute albumen, say one part white of egg to three parts water.

The malt process has been very successful in some operators' hands; but others have not done well with it. We prefer Fothergill's.—Ed.]

LOST IN FOG!

To the EDITOR.

SIR,—I beg to trouble you again for a little advice. I am terribly bothered with "fogging" of my plates. The Photographic Guide Books say it may proceed from alkalinity of the bath; but on testing mine it always gives a pink tinge with litmus. Again, they say it may proceed from super-saturation with iodide of silver; but it cannot be that in my case, as I have added six ounces distilled water to sixteen ounces bath, and made up the deficiency with nitrate of silver. I was completely put to a stand the other day by the plates being all fogged and *streaked* from top to bottom in the direction of the dip, and no image at all could I get, although I tried all sorts of exposure and all sizes of stops. Can you explain this? Sometimes I have got my bath right, but cannot get my negatives intense enough.

Ought a good negative to require more doses of pyrogallic developer than one? I use half an ounce of pyrogallic developer (three grains pyrogallic to one ounce) and twenty drops of a thirty-grain solution of nitrate of silver for a stereoscopic plate.

I had a most provoking mishap the other day. I went down to the ruins of an abbey, about three miles distant, and carried all the apparatus, tent, &c., for the wet process. When I commenced I found the plates all blackened in developing. A photographic friend had been kind enough to dose the bath with ammonia and make it quicken. However, having some acetic acid, I neutralised or acidified it, and managed to get about four clear positives on glass for my day's work.—I am, yours, &c.,

OLD FOGEY!

[You should bear in mind that excess of nitric acid in the bath is a cause of fogging quite as much as excess of oxide of silver, when you work with a collodion not containing bromide. With reference to super-saturation with iodide of silver, we do not quite understand how it can happen; but of this we are sure, viz., that you have added too much of the uniodised solution in applying the remedy.

Unless your collodion contains a bromide, the developer is made with three times more pyrogallic acid than is necessary. The negative on a stereoscopic plate is often of the right density without any addition of nitrate of silver, unless the collodion is of bad quality, or is bromo-iodised.

Your friend acted unadvisedly in dropping ammonia into the bath at random. A grain or two of carbonate of soda would have been safer in the hands of a beginner.—ED.]

CLEANING GLASS—PROTRACTED EXPOSURE.

To the EDITOR.

SIR,—I am quite at a loss for a plan for cleaning glasses. I have tried Tripoli powder, which is too expensive; gilder's whiting, which causes too much dust in my glass house.

I have been thinking of a strong solution of potash, soda pearl ash, or nitric or sulphuric acid, intending to leave plates in this until wanted, then wash well in clean water, and carefully dry with two clean cloths, finishing them with chamois leather. Would this be a good plan? Which of the above would be best and cheapest to make solution with? and what strength would be required?

I have latterly found my time of exposure for positive portraits thirty, forty, and fifty seconds, which is much too long in a glass house with good light. My lens is Derogy's half-plate, and has worked in eight and ten seconds. Do you think I may have put in the glasses of lens wrong after cleaning them? If so, how can I set them right?

My bath is in good order, thirty grains, and by test paper correct. I use Keith's developer, pro. nit. iron, made with nitrate of baryta, fresh made; Cammack's collodion, sometimes Keith's.

I would like to work much quicker, for taking dogs, horses, &c., but cannot attempt it in my present difficulty.

By favouring me with your advice on these points you will much oblige.—I am, yours, &c.,

Liverpool, July 12, 1860. MINNEHAHA.

[It is possible that your annoyance may arise from the kind of glass which you use: the colourless sheet glass is very apt to cause failures. Again, your cloths should be washed in soda and water only (no soap should be allowed on any account to be used), and then well rinsed in plenty of water. We think you will find the following a good plan for cleaning your plates:—Mix one part of nitric acid with three parts of rain water, and put your plates therein. If requisite rub the surface with a smooth cork, then hold under the tap and rinse copiously; place the plates on end to dry. Just before use pour on your plate a little *waste collodion*, and while still in a liquid state rub it all over the plate with a clean cloth, and continue this, occasionally breathing on the plate, until the whole of the collodion has been removed. We know of no better or quicker method than the above of obtaining a beautifully clean surface. If the plates have been previously used, and albumen or gelatine employed, they must first be cleansed in soda and water.

We do not think it probable that your lens is in fault with regard to the lengthened exposure; possibly the addition of a little bromide of cadmium to your collodion (say half a grain to the ounce), and a small excess of protosulphate of iron in the developer may assist you. Some operators find that a forty-grain nitrate bath works quicker than the ordinary thirty-grain one.—ED.]

ADDITION OF OLD COLLODION TO BATH.

To the EDITOR.

SIR,—My old bath having got out of order I made up a new one, the nitrate for which, along with the collodion for negatives, I purchased from one of the first houses in London, in the hope of being more successful than I had been for some time back; but I am much disappointed and dismayed to find myself in a worse position than before.

I iodised the new bath by pouring in about three ounces of old collodion to about sixty-five ounces of bath, thirty grains to the ounce. It is quite neutral, but it does not run freely from the plate, which, when taken out, has a greasy appearance, not like that which it has before being fully sensitised, but as if the bath had been thickened. There is also a sort of streak or cloudy appearance round the top and right-hand side of the plate, at about half-an-inch from the edge, a great part of which breaks off during the development and floats over the plate; moreover, the negatives are weak at all exposures.

As the bath smells strongly of ether, I have supposed that the old collodion has something to do with this state of things, which I have tried to get rid of without effect.—If you will kindly suggest a remedy you will confer a great favour on, yours, &c., HUNTS.

[We do not agree with the plan of adding so much old collodion to the bath, as the ether invariably makes the plates greasy. Remedy the defect as far as you can by pouring out the bath into a flat dish and leaving it exposed all night in a dark room, filling up with distilled water to the proper bulk on the following morning. The streak of which you complain is from allowing the plate to become too dry before dipping, and will disappear if you immerse more quickly.—ED.]

MANIPULATORY DETAILS.

To the EDITOR.

SIR,—I shall feel obliged by your informing me of the causes of the undermentioned imperfections in my negatives by the wet collodion process:—

1. Streaks on the plates, commencing from the bottom upwards.
2. The negatives have a black transparent appearance in the high lights, and, in consequence, print the pictures either very light without detail, or, if exposed to the sun for a longer time, the print is nearly black all over.
3. By adding the drops of silver solution to the developer, and pouring it on the plate, the solution goes muddy *directly*.
4. I thought of trying Keene's negative collodion. Would you advise me to do so?

With thanks for past favours, I am, yours, &c.,

July 12, 1860. AN AMATEUR IN A FIX.

[1. Clean your slide, and do not use dirty blotting-paper for draining on.—2. Probably bad collodion, or under exposure. See that your bath is not too acid.—3. This suggests the idea of the bath being in fault. Try intensifying with a developer containing half a grain *citric acid* to the ounce, in addition to the acetic acid. This will often keep the developer clear.—4. We have found Mr. Keene's collodion to be good.—ED.]

ANSWERS TO CORRESPONDENTS.

S. B.—Not till November next.

J. WINGRAVE (Coventry).—Bagnerre de Bigorre, Hautes Pyrenées.

JANE.—You can procure it at any operative chemist's—not at a *druggist's*.

R. A. C.—You print a little too darkly for the alkaline gold toning process.

R. A. L.—You will find the whole subject fully discussed in our last volume.

JAMES TURK.—Use a stronger solution of nitrate of silver: that you now employ gets too soon exhausted.

ALFRED.—We do not at all agree with the policy pursued in the publication you name, and certainly will not follow so shortsighted an example.

ONE IN A HOBBLE.—It is the collodion which is in fault: procure another sample from a different maker.

PRINTER.—We regret that we are unable to help you; we have constant enquiries for albumenised paper that can be relied on with certainty.

TOMASO.—Mr. Fothergill has worked in Italy with the process which bears his name. We believe he is now in that country.

F. A.—You must excuse us—we cannot comply with your request: we take our own course, quite irrespective of that pursued by the conductors of any other periodical.

ONE IN DOUBT.—You need not doubt: we can answer for the perfect good faith and excellent judgment of the gentleman you name. We know him personally and intimately.

The letters from Mr. JOHN L. DAVIS are "in type," but as we have further correspondence only just to hand relative to the same subject, we shall give the whole in our next.

JOHN A. STENNETT.—Hennah on the Collodion Process can be procured of Messrs. Knight & Son, Foster Lane, Cheapside, London. The A B C of Photography, of the London Stereoscopic Company, Cheapside.

POSITIVE PRINTING.—The continuation of MM. Davanne and Girard's report was presented at the last meeting of the French Photographic Society. A translation will appear in this Journal, commencing with the next number.

SAMUEL CROLY.—We quite agree with you: cameras are, as a rule, far too costly—that is to say, too luxuriously got up. Why not try your own hand at making what you cannot afford to buy. We have an intimate friend who made his own camera of milled-board, and dark slides, with a wood frame and sliding zinc shutters.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 124, Vol. VII.—AUGUST 15, 1860.

In our last we threw out a hint to those intending to select a dry process upon glass to wait until after the publication of this number of the Journal before finally adopting one. We did so on account of certain rumours which reached us, to the effect that an improvement of some importance had been introduced into the collodio-albumen process by some gentlemen belonging to the Manchester Society; and though at the time we were not acquainted with its nature, we had sufficient faith in the skill of the Manchester photographers, and in the discrimination of our informant, not to feel any hesitation in making the announcement. Our readers will perceive, on reference to a paper by Messrs. Petschler and Mann which we this day publish, that our confidence was by no means misplaced, and that another very important step in advance has been accomplished by the gentlemen we have named, especially as regards the comfort and convenience of operating upon collodio-albumenised plates. Unless we are very much mistaken, the discovery will also materially assist in furthering another project which we have just now at heart; but the discussion of its bearing upon this point we must reserve to a future opportunity.

Our readers will also find in the report of the proceedings at the last meeting of the Manchester Society, at which meeting the paper adverted to was read, some very valuable practical hints relative to the details of manipulation and application of the novel discovery that plates can be prepared in such a way as to be quite uninjured by exposure to strong ordinary daylight, and yet rendered sensitive by merely being washed in a little filtered water in the dark, or in non-actinic light, and subsequently dried previously to being exposed in the ordinary way in the camera. What renders it of still higher value is the fact that the preparation differs very little from the method ordinarily pursued, the difference being a simplification instead of a complication of the process.

With regard to its efficiency we have been favoured with an opportunity of judging—a proof from a negative ten inches by eight, executed by Mr. Petschler, being before us. It is a counterpart of one laid before the Manchester Society, and quite bears out the statements made with respect to the efficacy of this method of manipulation—foreground and distance being both properly exposed and rendered. The subject consists of a house on the right of the spectator, with farm-buildings on the left; a hedge, loose stone wall, and broken gate, in the foreground; a mass of trees surround the house, and an expansive view of open country, bounded by low hills, forms the background. The foliage is somewhat deficient from *movement*, not from any fault in the process; and from the tone of the paper we are convinced that the negative is capable of producing a better result than that before us.

We have a few observations to make, as well in reference to the paper itself as to some points in the discussion which ensued. It will be found recorded that, in reply to a question by a member of the Manchester Society, as to how the discovery was made, Mr. Petschler stated that *it arose* in consequence of his having attempted to render sensitive a collodio-albumenised plate in a bath of aceto-nitrate of silver containing too small a quantity of liquid to cover the whole of the plate — that the part of the film unacted upon by the silver solution was only moistened by water in the subsequent washing — and that, on development, this part was affected more energetically by the developer than the remainder: whereupon the questioner observed, "It was an accident, then." Every discovery is, of course, more or less accidental in one sense; but the merit of the discovery does not rest in this, but in the faculty of *turning an accident to useful account*, and from which the fortuitous circumstance which gave rise to the opportunity does not detract in the smallest degree. A phenomenon, previously unknown to photographers, occurs, and this only to a very limited extent: it is noted, reasoned upon, the cause suspected, tested, found to be correct, and immediately utilised for further operations. Surely this is a discovery in the strictest sense of the term.

Regarding the assumed *rationale* we are not quite so well satisfied, or rather we think that further examination is required before adopting it as a settled affair. We do not feel certain that it may not turn out to be that immersion in water and subsequent drying of a *sensitive* plate upon which the light has been allowed to act removes the impression and restores the sensitiveness: it is at any rate an experiment worth a careful trial. There are two or three facts which lead us to this conjecture. It was noticed by Mr. Osborne, of the Birmingham Society, that Dr. Norris's dry plates which had been exposed had their sensitive condition restored by being exposed to the vapour of acetic acid. The fact was verified by our *collaborateur*, Mr. Hardwich; but the cause of such an effect neither of us could satisfactorily solve. Three years or more ago we discovered that plates preserved in various ways could have their sensitiveness restored after exposure by immersion in water containing a few drops of tincture of iodine — a circumstance which we published at the time, and which we considered to be explained by a combination of the iodine with the presumed reduced silver. Thirdly, when making experiments about two years back with the proto-iodide of mercury, for the purpose of applying it to the production of positive proofs upon paper, we found that the scarlet image formed by the action of light gradually faded out if the paper were exposed to the air in the dark room — sometimes more rapidly than at others; but in either case, the paper, having resumed its normal yellow colour, proved to be just as sensitive to the light as when first prepared. But further: after washing some of these papers that had been exposed under a negative, with a view to a removal of the surplus free proto-*nitrate* of mercury that we had purposely left in the paper prior to exposure, with the idea of assisting, by its removal, to fix the red image, we were not a little astonished on drying the paper in the dark room to find the image fade out as perfectly as before, but with enormously increased rapidity, the paper being again restored to its original sensitive condition. Indeed, on one sheet of paper we must have produced at least a dozen different impressions in succession, so that we can be under no possible mistake as to the restoration of the sensitive-

ness after simple immersion in common water and drying. It has been remarked that Dr. Hill Norris's plates should not be left too long between exposure and development, as otherwise the image fades out; and lastly, a similar effect is produced on papers prepared with nitrate of uranium.

The drift of our argument, then, is as follows:—It is proved that in various ways the impression produced by light upon *sensitive* films of several kinds can be removed and the sensibility restored; that in some cases it takes place by simple exposure to the air (in which more or less moisture may be presumed to be present); and that in a portion at least of these cases, and in some others, immersion in water or some aqueous solution, with after-exposure to the air, produces a similar effect still more rapidly. We therefore come to the conclusion that it is highly probable that moisture may be the chief agent in effecting the restoration of the sensitive collodion, and that the iodine in one case, and the acetic acid in another, may have had little or nothing to do with the matter. We do no wish it to be understood that we deem this proved, but we think that enough has been stated to show that the experiment proposed deserves a trial.

We shall probably advert to this subject upon a future occasion, as there are many more highly interesting speculations that may be opened up. In the meantime we sincerely congratulate our numerous photographic brethren upon what we think bids fairly to be of considerable utility to all engaged in landscape photography, especially those unfortunates who have to submit their sensitive plates to the ordeal of a scrutiny by custom-house officers.

It will, doubtless, be in the recollection of our readers that lately an intimation was thrown out by Sir David Brewster relative to the supposed antiquity of the knowledge of stereoscopic principles, the supposition arising from the fact that an artist, named Jacopo Chimenti, who lived in the sixteenth century, had executed a pair of pictures, which are at present preserved in the museum at Lille, and which it was alleged, on being viewed in such a manner as to allow each eye to see only one of the designs, presented a stereoscopic effect. It is very unfortunate that when an announcement of any supposed fact is once made and subsequently proved to be erroneous, it is almost impossible to correct the false impression as thoroughly as is desirable; because there must always exist many persons who read the assertion but not the contradiction, while those who see the contradiction without the previous erroneous statement, can play but a very unimportant part in its rectification. Under these circumstances we conceive it to be advisable to draw special attention to a paragraph in the letter of our Paris correspondent, M. Ernest Lacan, which was published in our last number, and from which we learn that, in order to settle the question satisfactorily, our countryman, Mr. Bingham, who is a resident in Paris, took photographic copies of the alleged pair of stereographs, and laid them before the members of the French Photographic Society at the July meeting.

When placed in the stereoscope the two pictures united perfectly, but did not present the smallest effect of relief.

We think it is fair therefore to presume that, whatever may have been the object proposed by the artist in executing the two similar pictures, it was certainly not from any knowledge of the stereoscopic phenomenon, and that Sir David Brewster was in this instance wrong in his conjecture. It is but right to add that Sir David had not had ocular demonstration of the alleged fact when he threw out the suggestion.

ON A HITHERTO UNKNOWN PRINCIPLE IN SENSITISING DRY PLATES.

By Messrs. Petschler and E. Mann.

[Read by Mr. Mann at a Meeting of the Manchester Photographic Society, August 1, 1860.]

Mr. Petschler and myself having lately made several experiments on some modifications of the collodio-albumen process, we have now thought it desirable to lay the particulars of them before this Society; and we have great pleasure in doing so, as we believe we have some new chemical facts connected with the iodides and chlorides of silver to communicate.

The collodio-albumen process is an excellent one when the plates are used soon after preparation; but blistering of the film, and a deposit on the surface of the plates during development, are troubles known to all followers of this valuable dry process. The modification which we have the pleasure of bringing before your notice this evening has the following advantages:—the plates develop very quickly, and are remarkably clear and bright, and, most important of all, no second or aceto-nitrate of silver bath is required. As there cannot possibly be any free nitrate of silver left, the plates, upon theory, ought to keep as long, if not longer, than any known process.

The method we have adopted is as follows:—the plates are prepared as they would be for collodio-albumen, with this exception, that instead of coating the plates with iodised albumen they are covered with albumen containing about one or two grains of chloride of sodium to the ounce; the plate is then insensitive to light, and may be, after being allowed to drain and become surface-dry, either baked in the oven or dried before a hot fire.

Now comes the peculiarity which Mr. Petschler has the credit of having discovered, and which, though apparently trivial in itself, produces a most wonderful effect: instead of dipping the plates in an aceto-nitrate of silver bath, *they are simply washed thoroughly under a stream of water*, and this renders the film *again sensitive to light*, and after being dried are ready for exposure in the camera.

I will now endeavour to explain what we suppose to be the reason of this return of sensitiveness produced by the washing, and the real change which takes place.

It appears to us to be simply that the excess of chloride in the film makes the plate insensitive to light, and the washing dissolves out all the free chloride of sodium, and leaves nothing but the pure and insoluble silver salts behind. To satisfy ourselves that this was correct, and that some ascertainable change was effected, we took a stereoscopic prepared plate, and placed it in a dish, with just sufficient water to cover the surface, and after allowing it to soak for a few minutes, and shaking the water backwards and forwards over the plate, we placed some of the water in a glass measure, and tested it with a few drops of nitrate of silver solution, when immediately a very dense milky substance formed in the water, which was chloride of silver.

To make sure there were no chlorides in the water previously we dropped some silver into it beforehand, but no perceptible milky effect was produced: this test convinced us that a very important change was effected by the washing. We have also found that the ordinary iodised albumen plates, prepared for collodio-albumen, may be rendered sensitive in the same way, namely, simply washing away the free iodide of potassium, and leaving only the pure and insoluble iodide of silver behind. I will now describe a very peculiar difference in the effect of putting the plates prepared with iodised albumen and chlorided albumen in the second or aceto-nitrate bath. A plate with iodised albumen developed better on the part which had been dipped in the second silver bath; but here is a plate prepared with chlorided albumen and you will observe the very reverse, for the part which has been plunged in the silver has developed less than the part which was left out and only simply washed. There is also this very curious distinction between the chloride and the iodide: the former develops quicker and better when not put in a second silver bath, but the latter develops slowly, and comes out faintly when not so sensitised a second time.

We do not assert the process to be perfect, or better than collodio-albumen in its results, but leave the subject to your judgment, and to the test of further experiments.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 10.

M. Poitevin lately described a process for producing transmitted positives by a single operation. This process appeared simple, and more correct in theory than some which preceded it; and we were induced to give it a careful trial, especially so as it was stated that pictures had been obtained equal to the transparencies of M. Ferrier. A certain mode of producing such positives would be welcomed not only by many who wish to duplicate their negatives, but also by practitioners of the photogalvanographic and carbon-printing processes. We therefore commenced our experiments in earnest, and were determined to report success, if possible.

The principle upon which M. Poitevin's process is founded appears to be this:—that an actinically-impressed layer of iodide of silver upon collodion loses its latent image and returns to the normal state when iodide of potassium acts upon it in presence of white light. Without the assistance of light, however, the iodide of potassium does not discharge the image; and, therefore, we have only to expose a sensitive collodion plate, in the first instance, to full daylight, and afterwards to replace the free nitrate of silver upon its surface by free iodide of potassium. Then, if the camera image be projected upon the plate so prepared, the lights will obliterate the previous impression, but the shadows will leave it unaffected; consequently, on developing with a mixture of nitrate of silver and pyrogallic acid a transmitted positive will be obtained.

In commencing our critical examination of this process we thought it better to inquire, at the outset, whether the destruction of the latent image by iodide of potassium in conjunction with light, but not by the same iodide acting in the dark, was an established fact. On this point we have made many experiments, and the conclusion at length adopted is, that the effect of iodide of potassium in destroying an invisible image is greatly exalted by the co-operation of light, but that it takes place to a certain extent even without light. Very much seems to depend upon the vigour of the original actinic impression, since we found, on placing a wet collodion plate in the camera, and pointing the instrument at a landscape view for the proper period of time, that a solution of iodide of potassium applied in the yellow room instantly destroyed the *half-shadows*, but did not immediately destroy the sky; hence, on washing the plate with water, and treating it with mixed pyrogallic acid and nitrate of silver, a precipitate of reduced silver took place upon the sky. It was observable, however, that the sky, although not destroyed in the above experiment, was very considerably lowered in intensity, so that it developed of a violet-blue instead of a pure black or red. Therefore it may be concluded that the iodide of potassium produces an effect even in the dark; and, if our memory serves us, M. Poitevin indicated as much in his paper, and stated that the plates would suffer if kept too long after the iodide of potassium had been applied: our confidence in the process as theoretically sound is thus somewhat lessened.

Allowing that iodide of potassium discharges the latent image slowly, even in the dark, the inquiry next arises—what effect is produced by *free iodine?* We found that free iodine *instantly* removes the most vigorous image under any circumstances; so that it is possible that the effect of light in assisting the action of the iodide of potassium may depend upon a separation of the iodine from the base of the salt.

In our first attempts to carry out M. Poitevin's process practically we met with little or no success; but this, it afterwards appeared, was partly due to our having taken the wrong sort of collodion. The difficulty was to obtain dense blacks in the shadows of the transmitted positive. With a simply iodised collodion, the deposit was so excessively thin and blue that it became impossible to strengthen it by prolonged development. When, however, a bromo-iodised collodion was substituted, a better result was obtained, and a certain amount of the red tone could be detected; on seeing which we felt that there would be no difficulty in securing a more or less perfect black by carefully pushing the action. In explaining why a bromo-iodised collodion gave a more intense picture than one simply iodised, two circumstances must be borne in mind. We must remember, in the first place, that the plate had been exposed to the full rays of the sun; and, in the second, that it had been subsequently treated with iodide of potassium. Now it is found that bromo-iodide, although it gives a very weak picture in a dull light, takes a stronger impression than simple iodide in a powerful light; and, further, that the image upon a simply iodised collodion is much more easily discharged (to borrow an expression of Dr. Norris's) than the image upon a bromo-iodised collodion. For these reasons we recommend, with confidence, that those who try M. Poitevin's process should use a bromo-iodised collodion.

The mode of developing in this process seems also of consequence. At first we were satisfied by washing away the free iodide of potassium after it had done its work, and applying to the film a mixture of pyrogallic acid and nitrate of silver. This plan produced a picture, but it was not at all equal to what we afterwards obtained by following the original directions implicitly, and dipping the plate in a solution of nitrate of silver immediately before development.

The result of two or three days' experience of the working of M. Poitevin's process has left us greatly pleased with it as an illustration of the theory of photography, but far from being satisfied that presentable pictures can be obtained with certainty by its means. The exposure in the camera is longer than we anticipated, although it must be confessed that our experiments were made when both light and temperature were unfavourable. The pictures also were not sufficiently vigorous or well defined: there was an appearance of "halation" or fringing about the lines of the image which we fancied at the time would be removed if we could succeed in imparting a little more energy to the development. Evidently the iodide of potassium weakens the *attraction* which the iodide of silver actinically impressed ought to exert towards the reduced silver, and consequently the particles fall in an undecided and irregular manner, and there is a constant danger of spots and stains. Theoretically this state of things ought to be remedied by the proper kind of organic matter introduced with certain precautions. Our own experiments, however, with the organic matter were not successful; for in one instance the iodide of potassium did not properly discharge the image when the supporting basis contained organic matter, whilst in another, although a reversed image appeared, there was more or less evidence of fogging. Still we are of opinion that something may yet be done in this direction, and that the employment of an organic substance, in conjunction with a bromide or a chloride, offers the best chance of producing pictures with warm and velvety shadows, without which the transparent positives cannot be esteemed presentable as works of art.

THE RECENT SOLAR ECLIPSE.

THE BRITISH ASTRONOMICAL EXPEDITION: A PERSONAL NARRATIVE OF THE PHENOMENA OBSERVED.

By Walter Beck.

I venture, as one who had the honour of accompanying the recent astronomical expedition to the north of Spain, to intrude upon your columns, in the anticipation that a slight sketch of our proceedings and of the phenomena we observed may not be wholly uninteresting to your readers. Unfortunately I am necessitated to confine myself almost entirely to the movements of the party of which I was a member, since the observers were scattered over an extensive range of country, and means of intercommunication were limited. For the photographic phase of the observations I must refer your readers to Mr. De la Rue's letter in *The Times* of the 9th inst., and for the strictly scientific portion to the volume which it is intended shortly to publish.

Probably not even the express train on the morning of March 15th, 1858, conveyed so many astronomers to Swindon as did the 9h. 15m. from Paddington to Plymouth on July 6th, 1860. The luggage denoted the character of the passengers. Long boxes, evidently containing telescopes, barometer cases, &c., &c., marked with the words "Instruments for observation of the eclipse," abounded on the platform, and were piled in the luggage van.

It was late in the evening when we reached the magnificent troop ship *Himalaya*, which had been placed at the disposal of the Astronomer Royal by the Government. Glad enough were we after eight hours' rail to turn into our berths.

It was arranged that we should sail at ten o'clock next morning (Saturday), but before that hour arrived a boat came alongside from the *Hero*, inviting those who chose to visit that vessel—the one selected to convey the Prince of Wales on his transatlantic voyage. A considerable number availed themselves of this polite offer, and barely returned before the *Himalaya* slipped from the buoy and stood out to sea round the eastern end of the celebrated Plymouth Breakwater.

It was a lovely day, with a cloudless sky, and just sufficient wind to keep the heat from being oppressive. We passed about half a mile from the Eddystone, and not many hours elapsed before the land had sunk below the horizon.

The fact of our having left Plymouth had been communicated to Bilbao by telegaph, and lest we should arrive too early the engines were ordered to go at only half speed. Owing to the calmness of the sea the motion of the vessel was so slight as to interfere but little with photography, and several groups were taken by Mr. Downes with reasonable success.

Towards the afternoon the Astronomer Royal called a meeting of the members forming the expedition, received from the principals an account of what they and their assistants proposed to do, and delivered an able speech, commenting upon the information given, and pointing out the particularly interesting features which might be expected during the eclipse. Through the kindness of Mr. Vignolles every observer on board was furnished with a copy of

his valuable work on the subject, accompanied by a beautifully executed map of the north of Spain, showing, by means of lines, the track of the shadow, with the calculated duration of totality at various places.

After dinner, as we approached the dreaded Bay of Biscay, many were the speculations as to what sort of weather we should encounter; some affirming that the tempestuous character ascribed to that part of the Atlantic was a myth, whilst others held the contrary. The evening wore pleasantly on, being beguiled by the excellent vocal and instrumental performances of the ladies who accompanied us; and when, after sighting Ushant Light, we were told that we were fairly in the Bay, and when we found ourselves sailing on a placid moonlit sea with but little motion, we retired to rest in a comfortable state of mind as regarded the future.

On awaking in the early dawn, however, it was evident that the ocean still maintained its character for "faithlessness." The bulkheads were creaking loudly, all swinging lamps, &c., in oscillation, and to us landsmen it was difficult to stand still in the cabin. Fortunately, on going above, we found it was an *easterly* breeze that had raised this commotion, otherwise if it had been from the west the matter would have been far worse. It was not long ere the effects of the sea became apparent. The breakfast table was but thinly attended, many were in their berths, and others were to be seen in various stages, from that of utter despair to semi-joviality. The day passed by, and towards afternoon it became much calmer, and "with the sun the gale died down." Dinner was more patronised, and the indisposed took heart and refreshment. On the vessel went, "gliding through liquid leagues, sliding from horizon to horizon;" and when we came on deck on Monday morning we found ourselves in full view of the Spanish coast, with its bold cliffs and distant mountains. Along this we steamed, the signal for a pilot at the fore, and were not long ere we took one on board. An hour had not elapsed before another boat came alongside which had been waiting for us all night, and in a short time we dropped anchor in the roads of Portugalete, the entrance to the river Nervion, on which the city of Bilbao is situated. An excursion steamer crowded with people came out, which sailed round us several times with the hope that they would be admitted on board. This was felt to be impossible, owing to the necessity which existed for getting the instruments and luggage safely on shore.

Not long after Mr. Vignolles, and a number of English gentlemen employed on the railway, arrived in a steamer which he had kindly chartered to take us up the river to Bilbao, and bidding a temporary farewell to the *Himalaya*, and those of the expedition who were going with her to Santander, we found ourselves on the way to the city. We could not but admire the beauty of the scenery on either side of the Nervion—fine lofty hills interspersed with vineyards and corn-fields. Many were the anxious enquiries as to customs, and other ordeals through which we expected to pass; but we were agreeably disappointed, for the Government, true to its promise of affording us every facility, admitted us without even requiring our passports.

We now separated considerably, some accepting the hospitality of Mr. Vignolles and the members of the staff, others putting up at different hotels. We found ourselves amongst friends whom we seemed to have known for years, who did everything that lay in their power to make us comfortable, and laid us under obligations that I am sure none will ever forget. Conducted by these gentlemen we "did" the town in parties. In fact, we could almost fancy ourselves in a new England, and, as if to render the illusion complete, a cricket match came off at Portugalete next day, at which the astronomers were represented.

On the same morning Professor Airey held a meeting to decide on the different stations to be taken by the observers. The party to which I belonged consisted of Mr. Joseph Beck, Mr. Joseph Bonomi, and myself; and it was arranged that we should start the same evening by diligence with Mr. De la Rue's party for Miranda de Ebro. Night travelling is never the most agreeable thing in the world, even in a first-class carriage, but in a diligence it borders on the disagreeable. We were not sorry, therefore, when, after ten hours' intolerably dusty ride, we reached our destination, Mr. De la Rue having left us about two miles from Miranda in order to proceed to his station of Rivabellosa.

Here we again met with a most cordial reception from the staff of the Ebro line, and the engineers of the adjacent sections of the Bilbao and Tudela railway, and were quickly comfortably "located" in the *parador* of Don Cirilo Guinea.

It being Wednesday we had a week to pass before the eclipse, and this flew by rapidly, being employed in choosing our station and in walking about the country, whilst Mr. Bonomi made a series of valuable sketches, embracing all the objects of interest in the immediate vicinity, the curiosities of the place, &c. Occasionally also we saw gentlemen from the stations nearest Miranda, who came to the inn as a halting-place on the way to Rivabellosa or elsewhere. Being a sort of half-way house between Burgos and Vitoria, and on the high road to Madrid, there was also a constant bustle and continual arrivals and departures.

The weather was very ominous, and on the morning of the eventful day we mounted the little hill which formed our observatory with heavy masses of cloud rolling over our heads and but faint glimpses of blue sky. We were accompanied by Messrs. Preston, Weedon, and Roberts, of the staff, the others having proceeded to a lofty mountain near Haro, in order to make sure of a good view.

Mr. Joseph Beck was provided with a 5″ telescope, by Cook, to which an extremely ingenious apparatus had been applied, by the use of which he hoped to be enabled to detect the smallest symptom of polarisation in the corona. As his assistant he had appointed me to observe the polarisation of the atmosphere during the passage of the shadow—an intention which circumstances forced him to relinquish, and to direct me to observe the general effects. I therefore viewed the eclipse through an opera-glass, furnished with a slide in the eye-pieces containing three different shades of glass. Mr. Preston used a small telescope, mounted on a temporary stand, which afforded great facilities for looking at the sun at its high elevation. Messrs. Weedon and Roberts brought their theodolites, and by a few simple contrivances managed to make good use of them. Mr. Bonomi had been engaged for some days in preparing a panoramic view of the surrounding country, and had also kindly provided us with circles, divided by intersecting lines for facility in marking down the positions of the prominences; and had placed a series of tints at the side in order that their colour might be easily noted down at the time. We also possessed a chart showing what would be the positions of the principal planets and stars during totality. This was affixed to a board for easy reference. Greenwich time was brought up from Rivabellosa, but being destitute of chronometers we were unable to take any reliable time observations: this must be borne in mind. A cock, hen, and chickens, had been procured from Miranda, in order that we might observe the effects of the darkness upon them.

The eminence upon which we had taken our station was about 150 feet above the plain, and therefore about 1600 feet above mean sea level. It was clad with vines to the summit on the south side, and commanded a fine prospect, bounded on all sides by spurs from the Cantabrian Pyrenees; whilst, at our feet, the Ebro, with its poplar-lined banks, wound past the town of Miranda. We could plainly see Mr. De la Rue's observatory, and the people flocking near it; whilst the old Castle of Miranda was crowded—a circumstance which sadly annoyed the two French astronomers who had chosen that as their position.

About an hour before the commencement of the eclipse, the clouds broke in the direction of Pancorbo, where Professor Chevallier and Messrs. Wilson and Hammond had taken their station. The proportion of blue rapidly increased, and at the beginning of obscuration, on looking to windward, we appeared to be situated beneath a vast semicircle of clear sky, which augured well for a favourable result. Beautiful masses of cloud skirted the horizon, and, though some very considerable ones passed near the sun during the eclipse, not one interfered in the least with our uninterrupted view; and the few fleecy vapours that did cross his disc before totality served only as shades to the eye.

After first contact, we watched the moon slowly creeping over the sun's face, on which we had noticed a large spot. Within about thirteen minutes of totality Venus shone very distinctly, and was easily found by covering the sun with the hand.

A feeling of solemnity and quiet gathered over all things: we felt that an indefinable something was brooding around, and this was, doubtless, owing to the strange and unnatural effects produced by the peculiar amber-coloured light shed down by the rapidly decreasing sun. We seemed instinctively to wait for the approaching storm. The mountains were slightly veiled in misty blue, and in those on which the waning daylight fell we could apparently see every rift. The vines and patches of upland among the hills assumed a yellowish-green hue; the corn-fields appeared brighter in tone; the blue of the sky diminished in intensity, until it shaded down to the same tint as the distant country seen through a ravine. Nor did the smart wind which was blowing interfere with the weird and aerie effect upon the mind. Everything seemed hushed, sombre, and gloomy. Steadily the darkness in-

creased: the minuteness of detail in the distant landscape was lost. All at once the clouds and sky to the N.W. grew very black, as if stored with wind and rain: the gloom swept on, the last bright spot of sun went out, and the total phase had commenced.

I had been inclined to regard the accounts of former eclipses as rather enthusiastic, but I now found how far they fell short of reality. Description must always fail in such matters, and the effects so continually varied that it is impossible to embrace more than the leading features.

The dark body of the moon appeared as a puce-coloured space surrounded by the corona, whose streams of light, varying in intensity, and thus giving it a radiating appearance, stretched away for a distance which I shall not attempt to estimate, since we were unprovided with apparatus for making accurate measurements. Beyond its general limit extended different remarkable beams, one of which was conspicuous from its curved and filamentary appearance. The light was far greater than we had anticipated, but the wind rendered it very difficult to form any estimation of its brilliancy by comparison with the light of a candle. We observed no flickering motion, and almost the whole phenomenon came into view some seconds before totality, that portion being first visible which was farthest from the disappearing sun. Around the body of the moon there was a faint reddish tinge, and I remarked a peculiarly bright prominence on the S.W. edge, which shone with a pale red, resembling in colour a piece of phosphorus. It possessed a cap of white light of far greater intensity than the corona.

Intending more especially to devote my time to the general effect upon the landscape, I did not particularly seek for prominences. Others of our party noted four, and marked down their positions; and Mr. De la Rue's photoheliographic pictures have indelibly fixed the places, and perpetuated the forms of many others.

We observed but three planets, which were doubtless Venus, Jupiter, and Mercury, the clouds hiding the principal stars of the first magnitude which were expected to be visible. I was, however, informed that Professor Mädler at his station perceived stars of even the third magnitude. The gentlemen at Pancorbo were also favoured with glimpses of Sirius, Procyon, Castor, &c.

After gazing about half a minute at the glorious spectacle which the sun and heavens presented, I looked around on the earth. In the N.W. and S.E., the direction of the shadow's length, the distant mountains and horizon were shrouded in the deepest gloom, nor could I perceive the faintest traces of their outline. To the N.E. and S.W., where we looked almost at right angles to the path of the shadow, the sky was of a brassy, lurid red, owing to the refraction of the light from places exterior to the line of totality. This shaded rapidly off into the deepest indigo, which was the colour of the zenith. Against the fiery glow the serrated mountain ridges stood up in intense blackness, whilst dark clouds sailed across, or rather up, from the horizon.

For some short time after totality the light clouds overhead assumed an orange tint, whilst in the S. they floated across a sky of the most wonderful blue—a blue which gave the idea that the observer was gazing upon it through a transparent yellow medium. The beauty of the southern sky was vastly increased by the depth of colour in the zenith, and by contrast with the orange of the clouds. This, however, quickly faded, and the heavens in that direction became similar in hue to those in the N., N.E., E., and S.W., only that the mountains, being much nearer to us, the glow over their summits was the more striking. Below, the valley and town were enveloped in a sickly gloom, save where, at the foot of a little hill, similar to the one on which we were stationed, the Ebro sent up a very remarkable reflexion. The vines, and indeed every thing green, were peculiarly brilliant, and we could faintly hear the shouts from the people in the plain.

Throughout the whole time of totality the few persons who had climbed the hill to watch us observed a dead silence, and we were not subjected to the least annoyance.

The *tout ensemble* at this moment will never be forgotten—the grand yet dreary prospect, the impression of awe and quiet, will never be effaced from the memory. The larks, which had been singing as in the falling evening, had ceased a little before the total phase, and as the last spark of solar light died out the hen covered her chickens and the cock composed himself to sleep.

Suddenly the N.W. became illuminated: on the daylight came, with its blue light: it shot across the heavens: a bright spot on the moon's dark edge told that totality was over, and the shadow flew with inconceivable rapidity across the mountains. In a moment the distant country lighted up, and, forgetting to take any time observations, we ran together to congratulate each other on our success. Mr. Joseph Beck had observed polarisation in the corona, and we, who had not devoted ourselves to any special object, were anxious to compare notes, and know what had been seen. The transition from darkness to light was very rapid; but we quite forgot to make any observations on change in colours, or anything else.

After doing justice to a collation, spread in a rude tent which had been erected by the men who accompanied us, some of our party went down to Rivabellosa, and were delighted to find how successful Mr. De la Rue had been.

Next morning, news kept coming in of the favourable views which seemed to have been almost universally obtained. We were, however, sorry to find that Mr. Vignolles had been disappointed at the station he had chosen—the more so as we felt that his exertions had most materially contributed to our success. The party of the staff who had been to Haro returned after a capital time for observations.

The observers now began to turn their thoughts homeward, and to return to the sea-coast. A division of our party started on Saturday, and spent the Sunday at Vitoria, proceeding on the Monday to Bilbao. The road is remarkable for beautiful scenery, and one pass beyond Villareal is magnificent. Portions of our way reminded me of the New Forest, but the hills were grander and the country wilder.

At Bilbao the expedition reunited, and awaited the arrival of the *Himalaya* from Santander. On Thursday morning she came into Portugalete Roads, and lay there till the afternoon in order to afford the inhabitants of Bilbao an opportunity of going over her.

In the latter part of the day we bade farewell to our hospitable friends, steamed down the Nervion, and by half-past six were under weigh for England. Before nightfall we had sunk the high land of Spain. Next day the Astronomer Royal called a meeting, in which various resolutions were carried, the report of which has already appeared in *The Times*. It was the birthday of Professor Airey—a pleasing circumstance, to which due honour was done at dinner.

We experienced but little annoyance from the sea, as the whole passage home was very calm; and on Saturday morning we sighted Start Point, the landmark of homeward-bound vessels. The bows were occupied with members of the expedition, anxious to catch each feature of the coast. Portland Bill was passed, St. Alban's Head left behind, the Isle of Wight rose above the horizon, and we ran by the Needles and Hurst Castle. As we entered the Solent, Her Majesty the Queen steamed by in the *Victoria and Albert*, with the *Fairy* in company, and at four o'clock we dropped anchor in Spithead. The Astronomer Royal, accompanied by the expedition, met Capt. Seccombe on deck, and communicated to him their united thanks for his extremely polite attentions, and those of the officers, during the passage out and in. To this Capt. Seccombe responded in an appropriate speech, and the astronomers then gave three hearty cheers, and every one shook him by the hand.

The time now came for parting. Some went on shore in boats, while others landed in the *Pigmy*, which the Admiral had despatched to the *Himalaya*. Our delight at once more treading on English ground was modified by regret at the conclusion of an expedition so fraught with pleasure and important scientific results. Ineffaceable records of the "*Himalaya* expedition" have been left on every mind—remembrances which will endure to the last.

Such is a brief sketch of our travels. Doubtless the more perfect knowledge of many will correct me in different points, but I must ask their indulgence.

HAVING given above the personal and original narrative of a gentleman who took part in the astronomical observations, we now append Mr. Warren De la Rue's very interesting account of the proceedings of the Expedition, which, as embodying a report on the photographic phases of the Eclipse, will have a special interest for our readers.

IN the belief that an account of the proceedings of the several parties composing the Himalaya Expedition to Spain may have some interest for the general reader, I venture to address to you the following summary of the observations made at Rivabellosa, a village near Miranda del Ebro.

The station selected was a threshing-floor, situated in latitude 42 deg. 42 min. north, and longitude 11 min. 38 secs. west, at the height of 1,572 feet above the mean level of the sea. The magnetic variation was found to be 20 deg. 20 min. west. The locality, being bounded by a beautiful panorama formed by the distant Pyrenean range, was well situated for observing the effect of the eclipse on the landscape.

My party consisted, besides myself, of Mr. R. Beckley, the mechanical assistant of Kew, Mr. Downes, Mr. E. Beck, and Mr. Reynolds. Mr. Clark, who, at Mr. Vignolles's suggestion, had acted as our interpreter, also volunteered his services, which proved most valuable during the eclipse. Each of my assistants had allotted to him a separate

duty, and to their cheerful concurrence in carrying out my wishes must be attributed the successful result obtained.

My more important object was to endeavour to obtain photographs of the various phases of the eclipse by means of the Kew photoheliograph, an instrument I designed, at the suggestion of Sir John Herschel, for the special object of delineating the sun's image by means of photography. Although this was the primary object, I had also provided myself with ample means of observing the eclipse optically.

Our instruments and portable observatory, weighing very little short of two tons, were by previous arrangement conveyed in two days to my station by the kindness of Mr. Vignolles, to whom my thanks are especially due, and that of Mr. Bartlett, of the firm of Messrs. Brassey & Co., contractors of the Bilboa and Tudela Railway.

By the 12th of July we had erected the observatory, and by the 14th had obtained the first solar photograph in Spain. During these preliminary observations photographs were made of the surrounding panorama by Mr. Downes, and the geographical position of the station ascertained by myself.

The climate proved to be most uncertain, and much serious interruption was experienced by the clouds, which frequently completely obscured the sun for the whole day. Much inconvenience was also experienced from the dust, which rendered it necessary to obtain large supplies of water, in addition to that required for actual use, in order to keep the station moistened; otherwise this enemy to photography would have prevented any good result from being obtained.

The Kew photoheliograph consists of a tube having the form of a truncated pyramid, at the smaller (upper) end of which is fixed the object-glass, 3 4-10 inches in diameter, and 50 inches focal length. The focal image of the sun formed by the object-glass is 47-100ths of an inch in diameter, but, before it is allowed to fall on the sensitive plate, it is enlarged, by means of a secondary combination of lenses, to four inches in diameter.

The sensitive plates, six inches square, are placed at the large end of the pyramidal tube of the telescope. The tube is what is termed equatorially mounted, and is made to follow the diurnal motion of the sun by means of clockwork.

In taking pictures of the sun the aperture of the object-glass is usually reduced by means of stops to two inches.

Even with this small aperture the duration of the exposure of the sensitive plate to the action of the sun is a very small fraction of a second of time. The exposure of the plate to the sun's action is effected by means of a sliding plate, having a very narrow slit in it. The plate, which moves in the plane of the primary focus of the telescope, is drawn downwards by means of an opening, and previous to taking photographs is held up by a loop of thread fastened to a hook.

When a picture is required to be taken the thread is set on fire, and the plate flashes instantly across the axis of the telescope, and allows the image of the sun to pass momentarily through the slit on to the sensitive plate.

The clockwork driving apparatus, although convenient, might actually be dispensed with in taking sun pictures under ordinary circumstances, but at the period of totality in a solar eclipse it is necessary to expose the sensitive plate for some time to the more feeble light of the luminous prominences and corona, and then a clockwork driving apparatus becomes essential; and it is also necessary to employ the full aperture of the telescope.

The photoheliograph is provided with position wires, which may be removed at will; when left in the tube they become depicted as dark lines crossing the sun's disc whenever a sun picture is taken, and serve to determine with great accuracy the position of any markings on the sun or of the cusps with reference to a normal line, for instance, with a circle of declination.

The day previous to the eclipse was completely overcast, and the barometer was steadily falling. Nevertheless four dozen plates were cleaned, so as to be in readiness for the morrow; but the 18th proved in the morning to be as cloudy as its predecessor, and it was with very faint hopes that we went to our station. At twelve o'clock the sky began to clear, and we obtained a faint picture of the sun through the clouds; about half past twelve the clouds melted away as if by magic, and we had a clear blue sky (without a cloud visible), except on the distant mountains.

About 200 persons, who seemed to think that the eclipse was only to be seen from our station, rather interfered with our operations by their conversation, which completely prevented our hearing the beats of the chronometer; but the majority were persuaded, after a little while, to go on a neighbouring height, and the Alcalde Cirilo Guinea, to whom I wish publicly to tender my thanks, and the Civic Guards induced the remainder to speak in a lower tone.

Just before and after the eclipse sun pictures were made, and during the progress of the eclipse thirty-one photographs were obtained, the times of which are carefully registered.

These will serve hereafter to determine the path of the moon across the sun's disc and other data with considerable accuracy.

The serrated edge of the moon is perfectly depicted in all the photographs, and in some of them one cusp of the sun may be seen blunted by the projections of a lunar mountain, while the other remains perfectly sharp. I continued during the eclipse to observe the sun by means of a telescope of three inches' aperture, by Dallmeyer, and I am enabled to confirm the results obtained photographically. As I observed the progress of the eclipse, I gave the signal from time to time for the taking of a photograph, so that some have been procured just as the moon passed across any conspicuous solar spot.

When the sun was reduced to a small crescent, the shadows of all objects were depicted with wonderful sharpness and blackness, and as I cast my eyes on the now silent crowd they and the landscape appeared as if illuminated by the electric light, so brilliant were the lights, so sharp and black were the shadows.

The sky began to assume an indigo tint, and the landscape to be tinged with a bronze hue. But a few moments, however, could be spared for these observations, and when I placed my eye again to the telescope, and removed the dark glass, some minutes before the totality, I distinctly saw the whole of the lunar disc, and perceived a luminous prominence on the east of the zenith. This was quite visible, while the sun's image was reflected by a glass surface fixed at an angle of 45 deg., in the eye-piece, and its intensity therefore much diminished. The upper surface of the glass diagonal reflector I had, however, silvered to the extent of one-half, and as I brought into action the silvered half just previous to totality, I perceived a large sheet of prominences on the east. A little to the east of the zenith a brilliant cloud, quite detached from the sun, and at some distance from the moon, came into view. A few degrees to the west of the zenith a minute point was perceived at the commencement of the totality. South of the vertical only one small prominence was perceived.

The brilliancy of these prominences far exceeded that of the corona. Much detail was visible in the protuberances both of light and shadow and configuration. No appearance of Baily's beads was seen.

Casting the eye for a few seconds away from the telescope to behold the corona and the surrounding landscape, I was much surprised to find that the darkness was not so intense as I had anticipated.

The deep indigo of the upper part of the sky shading through a sepia tint into red and orange as it approached the horizon, the deep blue of the mountains as contrasted with the orange sky, and the peculiar light cast on the spectator, impressed me with a feeling of solemnity never to be effaced, and which was enhanced by the ear catching the sound of the village bells, which it appears had been tolled during the eclipse. I saw two stars to the east of the sun, which I believe to have been Jupiter and Venus, and observed that the corona did not extend generally more than about eight-tenths of the diameter of the moon beyond her limb, but that there were outlying rays of greater extent. A thought of my other duties recalled me, after a few seconds' gaze, from this enchanting scene, and I did not attempt any exact observations of the corona.

To return to photography, when the disc of the sun had diminished to a small crescent I gave the signal to discontinue the ordinary pictures, and to take away the stop of the object-glass in order to have the full aperture ready for the totality; and the instantaneous apparatus was also disconnected. The signal to prepare plates for the totality was also made, and three plates, by a preconcerted arrangement, were coated and then sensitised in an extremely sensitive neutral bath, which I had prepared expressly for the purpose. As I could collect no reliable data as to the intensity of the light of the luminous prominences and corona previous to the expedition, I was working under great disadvantages, and I confess from all that I could learn previously I had very faint hopes of depicting the corona at all, and I was led to think, from the colour of the prominences, that if I did get a picture of the corona, my only hope was to get the prominences as dark markings on the supposed more brilliant corona. Although my own observations during the totality gave me greater hopes of success, it was with a thrill of pleasure that, in answer to my questions, I learnt from Mr. Reynolds that the picture was coming out under the influence of the developing fluid.

This first plate had been exposed by previous arrangement just one minute, and only time enough remained for a second plate to be placed in the telescope.

Just at this period the wind rose and shook the observatory and telescope violently. Had it been possible for me to have known beforehand how intense the light of the prominences really was, there would have been no difficulty in obtaining the photographs in much less time, and I do not doubt that four might have been procured with an exposure of from 20 to 30 seconds each.

Previously to leaving London, trials had been made to obtain photographs of the moon with the Kew instrument, merely, however, for the purpose of judging of the time that might be necessary for the pictures of the corona, supposing it to be as bright as the moon, but not the slightest impression could be obtained by an exposure of one minute, whereas the pictures we have obtained of the luminous protuberances are all over-exposed, and the corona has clearly shown itself, so that the latter must be brighter than the light of the full moon.

The plates being only 6 inches square, while the sun's image is 4 inches in diameter, it will be seen that only a small extent of the corona could be depicted. I mention this in order that there may be no misconception on this point; had I desired to make photographs of the whole of the corona, I should have adopted a totally different arrangement.

My hand drawings were made by the aid of a series of lines ruled on glass, and placed in the focus of the eye-piece. This could be rotated through an arc of 90 deg., and I had two diagrams with similar lines set out on my drawing paper. With these aids I was able rapidly to make some measurements of position and extent of the prominences, and to complete two drawings. On comparing my sketches with the photographs, I was pleased to find that each completely confirmed the accuracy of the other.

My drawings were made in reference to the vertex, but it will be better to describe the markings as they were shown in the photographs in relation to a circle of declination. If the reader will suppose a circle to be divided into four quadrants by drawing two diameters across its centre at right angles, and that one of these diameters is made to coincide with a line drawn through the centre of the sun and the pole, calling the quadrants north-east, south-east, south-west, and north-west respectively, then the edge of the moon, both in the north-east and south-east quadrants, was at the commencement of totality nearly covered with the luminous prominences which extended over an arc of 130 deg. beyond her dark limb. These prominences were extremely brilliant, and far more so than the corona; they were not uniform in tint, and, with few exceptions, they did not present any colour approaching to red or rose; two had, however, a decided but faint rose tint. The surface of the luminous prominences next to the moon was, when first seen, very irregular, and far more so than was attributable to mountains as seen in profile on the moon's edge. This irregular outline may, however, be explained by supposing the prominences to have been first seen floating like clouds in a transparent atmosphere at some distance from the sun's surface, and consequently from the moon's edge—a supposition which is supported by the fact that one such prominence or luminous cloud was seen distinctly detached, and at some distance from the dark moon.

At the commencement of the eclipse only one small mountain-like peak was to be seen in the north-west quadrant, and a curved one in the south-west quadrant. As the moon glided over the sun's disc, the inner outline of the prominences in the eastern hemisphere became less and less indented, and at last they were bounded by the nearly even outline of the moon's limb. As the eastern prominences became gradually covered, the mountain-like peak, seen at first as a mere point in the north-west quadrant, gradually grew in dimensions, then presented several points, and at last resembled somewhat a colossal ship in full sail; and extending from this through an arc of 60 deg., there came into view, in the north-west quadrant, a long streak of luminous prominences, varying in breadth and with a few points projecting outwards. This streak became very jagged in its inner outline as the moon glided off from it, just previous to the sun's reappearance—these luminous prominences presenting the same phenomena as those on the eastern edge; that is, appearing like clouds floating in a transparent atmosphere, a little distance from the sun.

It will render the detailed description I now propose to give of the several luminous protuberances, as measured in the photographs, more clear if the reader will provide himself with a circle divided into 360 deg., and number the degrees in the reverse order of the figures on a watch—namely, from right to left.

Placing 360, which represents the north point (not the vertex) uppermost, the east point, or 90 deg., will be at the left; 180 deg., or the south point, at the bottom; and 270 deg., the west point, at the right hand. Eastward from the north point there was conspicuously visible a brilliant prominence, the summit of which, as the moon glided along, was seen to curve in two opposite directions from a radial line, the curved portions being far less brilliant than the stem, which touched the moon's limb throughout the totality. The centre of the stem was 28 deg. from the north point, and it was about 1 minute of arc broad (28,000 miles nearly). It extended fully 1½ minute, or 42,000 miles, beyond the moon's limb. This protuberance was so brilliant that I perceived it several minutes before the totality, and it must, without doubt, have been seen by all observers provided with good telescopes. It may, therefore, be conveniently made a starting-point to which all protuberances of which I shall speak may be referred by those astronomers who observed the prominences in regard to the vertex, by taking into account the angular distances of the several prominences from this one.

At 57 deg. was situated the northern extremity of a remarkable detached curved cloud, which, when first seen, was about half a minute (14,000 miles) beyond the position occupied by the moon's dark limb. It presented a double curvature on its northern side, both curvatures being convex towards the north. It inclined in a curved direction at about an angle of 60 deg. from a radius towards the east, and was a minute and a half (42,000 miles) long. As the moon glided onwards in her course she approached it gradually, and at last touched the extreme point of this floating cloud, which glowed with all the brilliancy of one of our own terrestrial clouds at sunset. It presented a decided rose tint.

At 72 deg. from the north a protuberance, in shape reminding one of a boomerang, imprinted itself on the sensitive plate, although it was not visible to me in the telescope. The stem was 2 min. long (56,000 miles), the point was bent towards the north, inclining downwards over towards the extremity of the detached cloud. Midway down the stem was a branch curving upwards, so that, on close scrutiny, the boomerang protuberance was not unlike the capital letter G in ordinary writing. It is a very curious circumstance that this protuberance imprinted itself distinctly, although it did not attract the eye directed especially to that locality. This may be accounted for on the supposition that it emitted a feeble purple light.

Between the last-named protuberances (the floating cloud and the boomerang) there was a low and long luminous streak, not more than a quarter of a minute broad, and extending in length about 8 deg. along the moon's limb.

From the stem of the boomerang, extending from 72 to 135 deg., there was a long streak of luminous cloud, commencing with the thinnest possible streak near the boomerang, and then becoming broader, but in no part exceeding a quarter of a minute in breadth, until it reached the position of 111 deg., when a skittle-like thickening took place, half a minute broad in the broadest part. Projecting from the commencement of this skittle were some faint projections, which imprinted themselves on the sensitive

plate, but I did not see them in the telescope. From 129 deg. to 135 deg. there was a considerable enlargement of the streak, which widened out to fully one minute in breadth (28,000 miles). This was bounded by curved lines, and was extremely brilliant. Just in the neighbourhood of this thickening—namely, between 115 deg. and 140 deg.—the corona was very bright, and one of the long streamers was to be seen curving towards the north.

At 154 deg. a protuberance, curving northwards, and not unlike a bishop's mitre, existed, which extended from the moon's limb a distance of 1·5 min. (42,000 miles); it was very much fainter towards the point than near the stem. A very faint streak of light connected the mitre-like protuberance with the long streak.

The long streak and nearly all the mitre-shaped protuberance were covered by the moon before the totality ended, but the floating cloud and the first-named northern protuberance were visible during the whole time.

At the commencement of the totality only two protuberances were visible in the western half of the moon's disc—namely, following the order of the preceding description, one, the centre of which was situated at 194 deg., consisted of a thin streak less than a quarter of a minute broad, and extended over an arc of 5½ deg. on the moon's limb at 197 deg., a point curving towards the south, projected about ⅓ min. This projection was completely covered as the moon advanced. The other projection was the mountain-like peak, the centre of which was situated at 348 deg. This peak, at first not more than ½ min. high, grew to considerable dimensions as the moon glided away from it, and assumed, as was before said, the appearance of a ship in full sail, the summit, or mainmast, extending more than 1½ min., and the case or hull of the vessel measuring 10 deg. on the moon's limb.

As the moon glided on there came into view a long streak extending from 280 deg. to 340 deg., where it just touched the hull of the ship. This streak was in some parts a mere line, and bounded by curved lines both on the under and upper side. It thickened to about ½ min. between 300 deg. and 310 deg., at both of which places two short horn-like projections were to be seen.

At 263 deg. and 278 deg. there came into view two small projections, one extending ½ min., and the second ½ min., from the moon's disc.

I am, Sir, your obedient servant,

The Observatory, Cranford, Middlesex. WARREN DE LA RUE.

THE AUTOMATIC CAMERA OF M. BERTSCH.

M. Bertsch has named the little instrument to which he called the attention of the members of the French Photographic Society at its last meeting the *automatic camera*, as it acts, to a certain extent, *per se*. It may be used either for wet or dry processes; and, if dry collodion or albumenised plates are employed, it may be placed in the hands of a person quite unacquainted with photographic manipulations. It is the camera to which M. Bertsch referred in his paper *On the Enlargement of Negatives*, given at page 217 of the present volume, as specially adapted for obtaining the small and very sharp negatives necessary for producing artistic and well-defined positive prints by enlargement.

The camera, constructed of metal, is about 3½ inches square, and carries a plate 2½ inches square, sufficiently large for a single stereoscopic view; but it has neither plate-frame nor focussing-glass, as the position of the plate is previously determined, on the construction of the instrument, to occupy a plane that is mathematically in focus for every object or plane that is twenty paces distant from the lens. In place of the focussing-glass, however, on the top of the camera a small quadrant is placed, adjustible by a circular guide and having a square opening crossed by threads, which, together with a spirit-level, permit the verticality of the camera and the position of the picture it is wished to obtain on the plate to be seen at a glance. When the objects are comprised within the frame of the quadrant, it is certain that they will be equally projected upon the sensitive plate. These arrangements are, of course, primarily dependent upon the optical construction of the lens employed; but of this essential part M. Bertsch gives few particulars or data from which its peculiarities may be deduced. He simply states that the single combination lens he has constructed is achromatised by dense flint of great dispersive power; that, notwithstanding the shortness of its focus, it is aplanatic over a field 2½ inches square, with an angle of aperture of 33°; and that as the pencils constituting the image are very acute, and on account of the exactness of the focus the impression is rapid, admits of people in motion being taken, as the pictures he exhibited proved. Neither the principal focal length of the lens or the diameter of the diaphragm are given.

As the front and back walls of the camera are made perfectly parallel to each other, and from the whole being constructed in metal, they cannot be warped; and as all slides and frames are dispensed with after the focus has been once adjusted, every source of error that can arise in the position of the plate in relation to the lens is avoided.

The camera is placed on a stand that folds up so as to form a walking stick, the height of which is calculated for the field of vision at twenty paces to form with the line of the horizon an angle of 15°.

The negatives obtained by this camera yield images of the greatest perfection up to thirty inches in diameter. One negative, examined by a microscope, showed clearly the hour on a public clock situated at a distance of 1600 yards; also the bars on the sails of a windmill in the extreme distance, as well as the minutest details in objects at a distance of only twenty paces.

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING THE PHOTOGRAPHIC IMAGE.

Report of the Committee, consisting of Messrs. Maskelyne, Hadow, Hardwich, *and* Llewelyn.

(Continued from page 221.)

In the photographic processes in which the chloride of silver is employed, it is to be borne in mind that the chloride of silver is not used by itself—nay, by itself is quite inadequate to the production of the deep colour requisite for photographic effects. It is used in fact always in conjunction with nitrate of silver, and also, it must be added, with organic substances, among which the cellulose of the paper and the glue-like size are prominent. The action of the nitrate of silver needs little explanation; it supplies continually a fresh surface of chloride of silver, formed by part of the chlorine given off from the surface of the original chloride, which unites at once with the silver of the nitrates, and simultaneously becomes blackened by the action of the light. It is singular, however, that it has escaped the observation of the chemists who have experimented on this point that an oxide of chlorine is also formed at the same time, as may be shown by the renewed deposit of chloride of silver which is produced in the supernatant nitrate by the addition to it of sulphurous acid. That the darker compound produced by the presence of nitrate of silver is in no respect different, save that it is a more abundant deposit, from that formed from the chloride alone, is evidenced by the identity of its reactions with those of the latter. For here, again, dilute nitric acid of sufficient strength to dissolve silver at 112°, is inert in its action on this bluish-black compound. Chlorhydric acid, if not sufficiently dilute, renders it somewhat paler, and gives a brownish hue to its slaty violet, but otherwise does not alter it. Hyposulphite of soda dissolves nearly the whole if sufficiently strong, leaving but a trace of metallic silver; and ammonia acts in a similar manner, while cyanide of potassium appears entirely to dissolve it.

In order to be satisfied that the bluish slate-coloured substance formed in the presence of nitrate of silver by the action of light on the chloride was not an oxychloride, an attempt was made to form such an oxychloride by operating on the chocolate-coloured substance so often alluded to. Boiled with caustic potash, this became dark brown; but nitric acid restored to it its chocolate tint. The substance operated on in this experiment was formed from the citrate by the action of hydrogen (in this case in the presence of nitrate of silver), and treatment of the products as before, by chlorhydric and nitric acids in succession.

We consider that we are justified in drawing the following conclusions:—

1. That the action of the light on chloride of silver is to reduce it, in so far as it is able to penetrate its substance, to the state of a subchloride.

2. That in the presence of nitrate of silver this deposit of subchloride is necessarily more plentiful, while some part of the liberated chlorine passes into an oxide, which prevents a portion of the chlorine set free from conducing to the formation of fresh subchloride.

From this point we may proceed to the discussion of the photographic image in more complex, but, for the photographist, more available forms. And in doing so, we must at the outset bear in mind that the image varies in its character in different stages of the photographic process. The first result obtained by the light, even if it be the same in all stages of the solarisation, is not the result which is in many cases left after the fixing solution has performed its work; but it is perhaps more interesting, as indicating the nature of the change effected by the light, independent of the chemical reagents which are afterwards applied.

In endeavouring to reduce into orderly arrangement the great number of photographic results which this inquiry involves, it seemed best to sever at the outset two series of them which bear but little relation to each other—namely, the images obtained by development, and those which are formed visibly by the light. Commencing with the latter of these, the attention is at once arrested by the processes involving the use of chloride of silver in conjunction with the nitrate of that metal.

The rationale of the union of these two compounds for the production of an effect far greater than that upon the chloride alone has been shown; but, practically, in photographic processes there are other agents present in the paper, or purposely introduced into it, which play a part in the photochemical change hardly less important than that of the silver salts themselves.

We may fairly inquire, in the first instance, whether the presence of the fibre of the paper itself may not assist in effecting decom-

positions under the influence of light. To determine this point, Swedish filtering paper, as the type of the most uniform and pure fibre of paper that could be procured, was treated with nitrate of silver alone: on being exposed for some hours, it exhibited a pale-reddish stain, which after several days' insolation reached no deeper tone than a brown. The substitution of ammonio-nitrate of silver for the nitrate gave a rapidity to the change, and ultimately a depth of opacity to the result, by affording an antagonism, as we suppose, to the influence of the nitric acid. The reactions of the darkened ammonio-nitrate paper are as follow:—Ammonia does not otherwise affect it, than that treatment therewith (probably by action on the tissue of the paper) makes it slightly more readily acted on by other reagents. Nitric acid, though exceedingly dilute, rapidly dissolves it. Indeed an acid so far diluted that it took many hours to destroy the substance left by treating with ammonia Swedish paper that had been prepared with chloride of silver and subsequently darkened in the sun, was able to destroy this bronzed image formed by the ammonio-nitrate in a few minutes. Cyanide of potassium in presence of air rapidly destroys it, but not so rapidly as it does the image on chloride of silver just alluded to.

It would be difficult, from the above reactions, to come to any positive opinion on the nature of the photochemically changed substance left by the ammonio-nitrate of silver on pure tissue of paper. But that this tissue is not without a part to play in the changes which the oxide of silver undergoes, perhaps even a more important one than that of an absorber of oxygen, seems indicated by one curious experiment. Swedish filtering paper treated with nitrate of silver, and while still moist touched with a solution of protosulphate of iron, gives a grey stain easily recognised as metallic silver. When, however, it is suffered to dry (of course in the dark), the stain thus formed, instead of grey, exhibits a dense black tone, which immediately afterwards passes on into a brown. The former of these is probably suboxide.

(To be continued.)

DRY COLLODION.

By Chas. A. Seely.

The desirableness of a good dry collodion process is well appreciated, and it is as well understood that we have no process which completely satisfies the wants of the devotees of photography. We cannot and should not be content till we are able to prepare dry plates with as much certainty as we do the wet.

It was found at an early day that the wet plate simply washed and dried, although sometimes giving a good result, could not be depended on. The virtue of the wet plate was attributed to the moisture, and the first attempts to prepare plates so that they should preserve their good qualities for a long time, consisted in methods of retaining the moisture. These methods were, 1st, Enclosing the plate in a damp box, or covering it with a sheet of glass, so that evaporation could not take place; 2nd, The use of substances like honey, syrup, nitrate of magnesia, &c., which had the property of retaining moisture. Then came the Taupenot process which was a kind of combination of the albumen and collodion, and finally the Fothergill process which is perhaps the ultimate simplification of the Taupenot process. Also, instead of albumen, gelatine, dextrine, gum arabic, &c., have been used, and in turn have been favourites.

Most of the attempts at solution of the dry collodion problem have been altogether empirical. Experiments have been made at random in the vain hope that something might by chance turn up. It is best to work after theory—a wrong one is better than none.

I have seen no theory distinctly laid down of the dry collodion, except that of M. Robiquet, which supposes that on drying the particles of iodide of silver in the collodion film they become separated from each other, and from that cause the forces which are active in bringing about reduction in development cannot have effect, and that it is therefore necessary to add such a substance as will keep up a connexion or continuity of the particles. The substance he prefers is some gum resin like copal or rosin to be dissolved in the collodion. The theory is evidently an attempt to account for the fact that rosin is of great utility; and in my opinion it is not worthy of a serious argument.

The theory of dry collodion which seems to harmonise with the known facts, is as follows:—Salts of silver are decomposed under the action of light only in the presence of organic matter. But the rapidity and kind of decomposition materially depends upon the kind of organic matter. And there is organic matter which is quite powerless to effect any decomposition—such is gun cotton. Pure gun cotton is remarkably stable in the presence of reagents, which rapidly destroy almost all other organic substances. Pure gun cotton moistened with nitrate of silver is unchanged in the light. Hence a surface of gun cotton imbued with silver salts is not all that is required for the photographic result. Now, in the ordinary collodion process an abundance of the most suitable organic matter (ether, alcohol, &c., or substances generated by their reaction) is present, and we find the process rapid and certain. How are the circumstances changed when the sensitised plate is washed and dried? The water used in washing carries away whatever is soluble, and on drying whatever is volatile is also removed, so that, with the washing and drying, the matter which is necessary for the photogenic reaction is not present.

If this theory be the truth the problem is much simplified. The most suitable organic matter must be selected, and then we may determine how it shall be introduced into the film, whether by the bath, collodion, or subsequent to the sensitising. Of course this matter must not be volatile, or soluble in water at the final washing. The bath does not seem to be the proper vehicle, for the reason that they would probably react on each other, and it is likely that a suitable substance dissolving in the bath would not be carried away in the final washing. The introduction of the substance during or after the washing seems also objectionable, on account of the difficulty of securing an uniform penetration. The solution in the collodion, therefore, appears to be our most reasonable alternative; and when the suitable matter is found, soluble in collodion and not in water, the dry collodion process will be reduced to its simplest form.—*American Journal of Photography.*

CELESTIAL AND INSTANTANEOUS PHOTOGRAPHY.

By Warren De la Rue, Esq., F.R.S., F.R.A.S., &c.

It will be in the recollection of our readers that, in the month of October of last year, we gave a copious abstract of Mr. De la Rue's Report on *Celestial Photography in England*, read at the Aberdeen meeting of the British Association for the Advancement of Science. But in an abstract which is intended to embrace a general view of the ideas propounded by the author, it is impossible to include any of the minute details so requisite to those who wish to apply photography to astronomical purposes; and as this application is daily increasing in interest we purpose extracting largely from the practical parts of the "Report," especially as the instructions given are also available for those wishing to follow out the production of Instantaneous Photography. We therefore commence with—

Actual Process employed at the Cranford Observatory.

With the view of facilitating the labours of others desirous of entering the field of photography, I will now describe, with all necessary minuteness, the process finally adopted after many trials and failures; I would remark at the same time that it is quite impossible to give such directions as will enable another operator to ensure perfect results, as this can only be attained by perseverance, long practice, and a strong determination to overcome obstacle after obstacle as it arises,—therefore, no one need hope for even moderate success if he dabbles in celestial photography in a desultory manner, as with an amusement to be taken up and laid aside.

In order to prosecute celestial photography successfully there must be, in close contiguity with the telescope, a photographic room, abundantly supplied with both common and rain water. The water-taps should project over a sink, so as to reach about a foot from the wall. The rain water is conveniently kept in and filtered by an ordinary stone-ware filter. The photographic room may be lighted generally by means of an ordinary Argand reading lamp, over the shade of which hangs a lantern-like curtain made of two thicknesses of deep-yellow calico; but the plate, during the development of the picture, must be illuminated locally by a night-light before which a yellow screen is placed. The photographic room should be furnished with a stove, burning wood or charcoal, which will keep alight for a long time, in order that its temperature may never fall much below 50° F. during the winter.

In my earlier experiments, the positive process was invariably employed on account of its greater rapidity; but so many details, visible by transmitted light in a positive, are lost when it is afterwards viewed by reflected light, that endeavours were made to render the negative process equally rapid. After many trials, I succeeded in this; and I now never have recourse to the positive process, except for some special object.

Glass used.—It is of course necessary to have the plate somewhat larger than the object to be taken; the size used when the telescope is employed as a Newtonian is 2⅝ inches by 3⅛ inches. When the pictures are taken by the direct method, the plates are circular, and 2⅝ inches in diameter. The outside diameter of the slide to contain the circular plate is 3¼ inches, the exact size of the cell of the diagonal mirror, so that no more light is stopped out by the plate-holder than by the small mirror.

The glass used is the "extra white patent plate," and I have it selected as free from specks and bubbles as possible, but nevertheless I have frequently to reject about one-third of those discs which are supplied to me.

Mode of Cleaning the Plate.—The glass is cleaned in the ordinary way by means of tripoli powder, mixed up with three parts of spirit of wine and one of liquid ammonia, to the consistence of cream. For drying the plates I am provided with *two** cloths, which, in the first instance, have been carefully washed with soda (avoiding the use of soap), and repeatedly rinsed in water. Each time after being used, these cloths are thoroughly dried, but they need not be washed for months together. For the final wiping of the plate a piece of wash-leather is employed, also carefully dried before being used.

A piece of grit-stone, such as is used by mowers to sharpen scythes, must be at hand, for the purpose of grinding the edges of the glass plate and making scratches on the margin of the two surfaces, in order to cause the more perfect adherence of the collodion.

The plate to be cleaned is placed on a sheet of cartridge paper, and rubbed thoroughly, first on one side, then on the other, with a piece of *new* cotton-wool moistened with the tripoli mixture, above described. It is then washed in a stream of water, the fingers being used, if necessary, to aid in removing the adhering tripoli. Holding the plate while still wet, and without touching the surface, one edge after the other is rubbed on the grit-stone; the glass imbeds itself in the friable stone, and thus the borders of the two surfaces get scratched, and the edge is ground at the same time. After the four edges have been so ground, or, if the plate be circular, the whole periphery has been rubbed, the hands and plate are well washed, to remove all grit, and the plate placed edgewise for a few seconds on a marble slab. With dry hands, I take up the plate by the edge, being now very careful not to touch the surface with the hand, and wipe it, first with one cloth, then thoroughly dry with the second, and lastly, rub both surfaces at the same time with the dry wash-leather. I afterwards breathe on each side of the plate, to ascertain whether it is clean, wipe off the condensed moisture and place the plate in a grooved box, with the bust surface turned to face a marked end of the box, so as to know on which side to pour the collodion. Proceeding in the above-described manner, I have never any failure attributable to a dirty plate, and can feel certain of obtaining four or five good pictures of the moon out of about seven plates generally used. I am usually, however, provided with one or two dozen clean plates, for it is desirable to have a sufficient reserve, and experience has proved that plates so cleaned may be used even after a week, if the box containing them be kept in a dry room.

The Bath.—It is of the utmost importance that the nitrate of silver bath should be in the most sensitive condition; the rapidity of the process appears to depend in a great measure on its not being in the slightest degree acid, but as nearly neutral as possible. It is almost needless to add that, for such a refined application of photography as that under consideration, the solution should be kept in glass in preference to gutta-percha. The vessel must be carefully covered, to exclude dust, and, from time to time, the solution should be filtered through pure filtering paper (Swedish paper). The nitrate of silver used in the preparation of the bath is invariably fused in my own laboratory, in quantities never exceeding a drachm at one time, the requisite heat being gradually applied, and care being taken not to raise the temperature higher than is necessary to effect the fusion.

The solution I employ is the ordinary one of thirty grains of nitrate of silver to the ounce of water, with a quarter of a grain of iodide of potassium. In the preparation of a bath, after the mixing of the nitrate of silver, dissolved in a small portion of the water, with the solution of iodide of potassium, it is customary to add the remaining chief bulk of water, which causes an immediate precipitation of iodide of silver, and then to filter the liquid after the lapse of half an hour. It is, however, advisable to agitate the solution from time to time, during several hours before it is filtered; for unless this is done, the bath does not become thoroughly saturated with iodide of silver, and has a tendency for some time to dissolve a portion of the iodide of silver which first forms in collodion immersed in it.

* It is disadvantageous to employ more cloths than are absolutely necessary

I avoid adding alcohol or acetic acid to the bath, for these substances impair its sensitiveness. As, after use for a certain time, the bath becomes charged with more or less alcohol and ether, and their products of oxidation, its properties become changed, and a picture cannot be taken with it with sufficient rapidity; when I find this to occur, I discard the bath and make a fresh one. The bath, in its most sensitive state, usually exhibits a very feeble alkaline reaction with reddened litmus paper, and if it be found to have a tendency to fog, it is corrected in this way:—A single drop of pure nitric acid is taken on the point of a glass rod, and mixed with a drachm of distilled water; with this diluted acid (1 to 60) I moisten the point of the glass rod and stir it about well in the bath, which contains about fourteen fluid ounces of solution, and make a trial. If it still fogs, the acidification is repeated; and thus, after several trials, the fault is corrected. It is better to proceed in this manner than to rely on litmus papers as a test for neutrality; the object being to retain the bath in as sensitive a state as possible, the test by light is the only one to be ultimately depended on.

Moist hydrated oxide of silver may be used to bring back a bath which has become acid by use to a neutral state, and by the subsequent careful addition of dilute nitric acid it may be made to work; but all additions of acetate of soda, carbonate of soda, or acetic acid, are quite inefficacious for correcting a bath that does not work satisfactorily. In order to obtain the extreme point of sensitiveness, the best plan on the whole is to make a new bath; the silver being, as is well known, easily recoverable from its solutions and in part, by evaporation and crystallisation, as nitrate.

(*To be continued.*)

ON FIXING POSITIVE PROOFS.*

By MM. Davanne and Girard.

The study of positive proofs presents so much complexity that the chemist cannot hope to include in one view the different peculiarities of that important operation. Besides, he is in fear that some accessory phenomena may disguise reactions of the greatest importance, and lead to erroneous conclusions. Influenced by this kind of experience, based upon certain experiments, we introduced into our last memoir some conclusions which it is necessary to modify.

Whilst preoccupied with the rapid decomposition which affects the hyposulphite bath, we fixed the limit of saturation at too low a point. This conclusion, derived from experiments erroneously interpreted, must be immediately modified; and if the limit of saturation of hyposulphite could cause the fading of proofs, other causes arise at the same time, the examination of which, though as yet overlooked, demand our greatest attention.

In fact, we may say that, besides the substances which we have already pointed out, we also meet with a certain quantity of free nitric acid, of which it is as easy to prove its origin as to demonstrate its presence. We know that chloride of silver, reduced by light, sets free chlorine, which, reacting on an equivalent quantity of free nitrate, again forms chloride of silver, whilst at the same time it sets free the nitric acid which the silver was combined with. It is to the successive reactions thus produced that the depth of the photographic image is due. Besides, it is easy to show evidence of the existence of this free acid. It is sufficient for this purpose to take a sheet of positive paper, prepared in the ordinary manner, divide it, expose one half to the full action of the sun, and keep the other half in darkness, and examine the nature of the soluble products which pertain to each piece. If each be immersed in a small quantity of water, and tincture of litmus be added to each of the filtered liquids, we may easily recognise, by the red colour which the reagent assumes, that the solarised sheet contains free nitric acid; whilst the portion protected from light shows, by the same experiment, that the paper contained no acid before it was exposed to the action of the sun. Doubtless washing the proofs in water removes the greater part; but the decomposing energy of this agent upon one of the commonest fixing solutions —viz., hyposulphite of soda—is such, that it appears more prudent, as will soon be shown, to employ in all cases a weak alkali to saturate the minute quantity of acid that resists the action of water.

We will now refer to the fixing itself, and give especial attention to the hyposulphite of soda, as the action of ammonia, as well as that of cyanide of potassium, is well known through our previous researches.

* Continued from page 162 of the present volume.

On fixing a proof by means of a fresh bath of hyposulphite of soda, experience demonstrates that the fixing is perfect, and analysis shows that *the fixing solution has not imparted to the proof any substance that can change it, either immediately or hereafter.* But this result, so clear and precise, is modified in a troublesome manner in a certain number of cases, which may all be referred to four distinct causes:—

1. The presence of free nitric acid in the darkened proof.
2. The limit of saturation of hyposulphite of soda by the salts of silver.
3. The action of light.
4. The employment of baths charged intentionally with acids, such as acetic acid.

PRESENCE OF NITRIC ACID.—As already established, the exposed sheet, on being removed from the frame, contains a certain quantity of nitric acid. It is easy to foresee the influence which would be exercised on the solution of hyposulphite of soda on contact with the acid. The reaction is thus indicated—

$$S^2 O^2, Na O + N O^5 = N O^5 Na O + S O^2 + S.$$

The nitric acid decomposed, the hyposulphite saturates the soda, and sets free hyposulphurous acid; but the latter, whose instability is well known, is immediately resolved into sulphurous acid and sulphur. The first of these bodies is without influence, but it is not so with the second; precipitated within the interstices of the paper, it carries with it an element of destruction, which, if it does not act immediately, nevertheless combines before long with the silver to form that yellow compound, that golden sulphide, whereof our former experiments have established the part it plays in the destruction of proofs.

The presence of free nitric acid in the darkened sheet, the energetic action which it exercises on the hyposulphite, demands from the photographer fresh precautions. Habituated hitherto to wash his proofs on their removal from the frame, to remove the excess of nitrate of silver that it may be recovered (of which excellent proceeding we shall soon show the efficacy), it is also necessary that he should submit them to the action of a substance capable of saturating the free acid which the water has not entirely removed. Bicarbonate of soda offers itself as the best reagent to effect this result. It is to this, in fact, that photographers will have recourse to avoid the new danger that we have pointed out. After having washed their proofs in water, so as to remove all free nitrate, it will suffice to let them rest some minutes in an aqueous solution of bicarbonate of soda of two or three per cent., or this may be more simply effected by adding the alkali in this proportion to the hyposulphite bath. Saturated in this manner, at the same moment the liquid penetrates the sheet the nitric acid can no longer exercise a destructive action upon the image.

LIMIT OF SATURATION OF THE HYPOSULPHITE.—We now attack the most complex and delicate part of the question that occupies our attention. Every photographer knows that when with precaution we throw a certain quantity of solution of nitrate of silver in a solution of hyposulphite of soda a white precipitate appears, which is immediately dissolved. This precipitate is hyposulphite of silver, $Ag\,O, S^2O^2$. It is a very unstable body, insoluble in water, and immediately it presents itself in the solid state is decomposed into sulphide of silver and sulphuric acid, according to the formula—

$$(a) \qquad Ag\,O, S^2O^2 + HO = Ag\,S + SO^3, HO.$$

This body can combine with hyposulphite of soda (as occurs when it is dissolved in it), and gives rise to two salts having very different properties. The one that first forms is when the hyposulphite is in excess, and corresponds to the formula—

$$(Ag\,O, S^2O^2) \quad (Na\,O, S^2O^2)\,2.$$

It is a white salt, very soluble in water, unalterable by the action of light, and can only be obtained in the crystalline state by precipitation from its aqueous solution by alcohol.

The second is formed when the hyposulphite of soda is in a relatively less quantity than the nitrate of silver, and corresponds to the formula—

$$Ag\,O, S^2O_2, \; Na\,O, S^2O^2.$$

It is a white salt, crystallising in magnificent prisms possessing the greatest brilliancy: it is nearly insoluble in water, undecomposable by light when in the dry state, but decomposing with extreme facility under its influence when in contact with water, and then giving rise to sulphide of silver, corresponding to the reaction *(a)*. The same compounds may be obtained by shaking recently precipitated chloride of silver in a solution of hyposulphite of soda.

(To be continued.)

NEW FORMULA FOR TONING BATH.

By M. l'Abbé LABORDE.

I HAVE tried nearly all the formulæ proposed for fixing and toning positive proofs by chloride of gold. Without attempting to discuss their merits or demerits, I shall content myself with making known a process to which I give the preference, because I have always found it the simplest and surest.

Dissolve in	Water	35 ounces.
	Acetate of soda	$7\frac{1}{2}$ drachms.
	Chloride of gold	15 grains.

The solution becomes colourless by degrees, and at the expiration of twenty-four hours it is ready for use. On removing the positive from the printing-frame it is washed in two or three waters, to remove the free nitrate of silver; it is then immersed in the gold bath, where it must be allowed to remain not more than twenty-five to thirty seconds, when the bath is first used. The action of this bath is stopped by putting the proof in water and rinsing it, then fix it as usual in hyposulphite of soda.

If the gold bath has been used before, its action is slower. Experience will enable the operator to see by the successive changes in tone the proof assumes when he should remove it from the bath. If it be removed too soon, the proof assumes a disagreeable red hue after it is fixed with the hypo.; on the other hand, if it be allowed to remain too long in the gold bath the proof assumes a cold blue tint. Between these two extremes there are a variety of tones of sepia and of violet, which can be secured by removing the proof at the proper moment. In proportion to the length of time the gold bath has been used so we must prolong the toning, until the required tint appears. The strength of the gold bath can be restored by adding fresh chloride of gold; but before making the addition we must take care that the solution is nearly colourless, for if the chloride of gold is not in combination it will, like other chlorides, weaken the proof.

STEREOGRAPHS.

Reminiscences of Scottish Scenes, by W. WOODWARD, *of Nottingham.*

IT is not long back that, in criticising a series of stereographs by Mr. Rodger, we remarked upon the irresistible desire evinced by every photographer to whom the occasion might offer of possessing himself of a record of the local features presented by the residence of the far-famed novelist, Sir Walter Scott. In this respect Mr. Woodward forms no exception; and first among the series now before us we notice—

ABBOTSFORD (No. 151), *from the South-East*—of which, by the way, there are two slides, and both bearing the same name and number. Mr. Rodger presented us with the front of the edifice, as seen from across the Tweed; Mr. Woodward treats us to a peep "behind the scenes," so that from an elevated terrace of mossy turf we overlook the grounds and inspect the beauties through the spring-clad branches of a few tastefully-disposed trees which half conceal them like the veil on the head of a blushing bride. As a background to the edifice itself (which is somewhat of a castellated structure), the undulating outline of a ridge of hills beyond the opposite bank of the river forms an appropriate contrast to the geometrical lines of the building, while in the immediate foreground in one of the slides the graceful form of a fine silver birch-tree is particularly noticeable, a feature that of itself will render this slide a favourite. But as an illustration of the aspect of Abbotsford itself we prefer the other specimen, taken from a somewhat different point of view—that one in which the scaly stem of a Scotch fir-tree is seen on the right hand, and a sapling sycamore in the centre. In this one the spectator overlooks the garden and outbuilding, and, being a trifle more distant, obtains a better general view of the whole place. It is a particularly pleasing and well-executed specimen of the artist's skill.

From his residence while living to his resting-place in the tomb is a natural transition; and in the Dryburgh Abbey series we find THE TOMB OF SIR WALTER SCOTT (No. 152), which, beyond the association, has no feature of special interest; for, though perfectly executed, it would be next to impossible to invest a very plain angular tomb, seen through a pair of ordinary iron gates, with any approach to the picturesque. In No. 153, however (ST. MARY'S AISLE, DRYBURGH ABBEY), the angle of the building in which the tomb is located, the case is somewhat different; and the contrast of the deep shadows under the arches with the dilapidated stonework of the pillars illuminated by the blaze of bright sunshine, relieved by the half-tones produced by the various mouldings, is very effective.

For picturesqueness and stereoscopic excellence, however, No. 157 far surpasses the preceding. It is the same subject (St. Mary's Aisle seen through the Door of the Cloister Court), the doorway being a mere ruin, partly overgrown with ivy, and choked with thistles, foxgloves, and other vegetable "vagabonds." This would form an admirable study for a large painting.

No. 154, East End (Interior), seems to be labelled rather jocosely. It is a low wall, on which a couple of monumental inscriptions can be discerned, and a mere fragment of some elaborate piece of sculpture. Rank grass forms the flooring, and trees and shrubs more than half of the background of this *interior!*

An avenue of trees looking towards the nave would have been better if the exposure had been more prolonged; and No. 158 (The Refectory Window, Dryburgh Abbey), an admirable subject, has been to some extent spoilt by over-development, the foliage of the trees in the foreground being spotty and snowy. This is a great pity, for in other respects the slide is an excellent and pleasing one.

Kelso Abbey, from the east, is another of the time-honoured ruins of which there are so many of the class in Scotland. The point of view from which the specimen before us is taken is a happy one, and the circumstances under which the exposure took place must have been favourable, for the perfect definition of the foliage of some trees in the foreground indicates a state of repose only possible under a total absence of that enemy of the landscape photographer—a breeze.

Melrose Abbey, like Abbotsford, finds much favour amongst the whole band of photographers; and deservedly so, for a more picturesque ruin it would be difficult to meet with. We consequently find it under many different aspects, from several points of the compass, interiors and exteriors. Perhaps, by the way, this is one reason why we find it so frequently taken; it affords so many different pictures, and all more or less good. In the slide now before us, taken from the south-east, a good general view of the whole edifice is included, and in which the south window and east window (both favourite subjects for interiors) are well seen.

No. 144 (South Aisle and West Window of Melrose Abbey) appears to us named upon the *lucus a non lucendo* principle, for there is neither an aisle or a window, properly so called, to be seen. The mere extremity of a window is rather indicated than seen in the distance, and the extreme corner of the aisle is all that represents it; but the slide is a very nice one for all that, and likely to be a favourite. *(To be continued.)*

Letters to a Photographic Friend.

No. III.

My dear Frank,

On resuming my photographic pilgrimage, on the second day, I turned my steps towards Mr. Skaife's Pistolgraph Depôt, at 47, Baker Street, where he has opened classes for instruction in Instantaneous Photography, and an operating-room for taking instantaneous portraits. His method is particularly applicable for taking portraits of children, aged persons, and animals, as, by means of his spring shutters, the time of exposure is *completely* under control, which is not the case with any other instantaneous arrangement I am acquainted with: all others are *entirely dependent* upon the action of springs, released by a trigger, and the shutters carrying the apertures must pass through a certain regular course of mechanical motion of greater or less rapidity, governed in amount by the strength of the spring employed, and *the amount of exposure* given *must*, in these instruments, *be preconcerted.* This is not the case with Mr. Skaife's invention; for, though he can employ a mechanical trigger to act upon the arrangements that open and close the shutters, the tip of the finger can be substituted, and any amount of exposure given, instantaneous or prolonged, according to the judgment of the operator: thus, in taking the photograph of a child or animal, on the slightest indication of motion being about to affect the subject, the tip of the finger is raised, and the plate is *simultaneously* protected from the action of light. In this case *the will* of the operator governs the amount of exposure, and not simply a mechanical power.

This invention is quite independent of the instrument which Mr. Skaife calls a pistolgraph, for which it was originally contrived, and may be arranged for a single or twin lens camera for taking instantaneous or other stereographs. If you wish to refresh your memory as to the construction of these shutters, you will find a description of them, given by Mr. Shadbolt, in the number for October 1st, 1858, of *The Liverpool and Manchester Photographic Journal.* What Mr. Skaife calls his chromo-crystal portraits are positive collodion photographs, taken by his Lilliputian Camera, and then backed up with deep blue or ruby-coloured glass. As the collodion film is cemented or fused between these glasses, they may be regarded as indestructible as far as the action of the air or rubbing is concerned. They vary in size from one and a-half inches to three-eighths of an inch in diameter after they are trimmed by the lapidary. They are the neatest and best-executed portraits I have seen suitable for mounting in bracelets, brooches, pins, or rings. An instantaneous view, taken on the day of my visit, delineated a vista of houses down Baker Street, a Hansom cab progressing onwards, with a boy and man in the act of running out of its way. The uplifted legs of these figures were sharply defined, without *the slightest trace* of any blur, so common in such subjects.

I spent some time in examining Mr. Skaife's interesting collection of portraits of well-known persons, equestrian groups in the Parks, boating scenes on the Thames, animals, &c., together with some enlarged views on paper produced from some of these.

From Baker Street to Duke Street, Manchester Square, is but a step, and here Mr. Hockin's warehouse naturally fell within my route. Mr. Hockin introduced to my notice a handy little camera for dry plates, fitted with twin lenses, *in situ*, and six double slides in the belly of the instrument. Hinged doors shut in both ends under lock and key, and thus the framework forms the packing case for all things necessary on a tour; in fact, it is just the kind of thing one could send down to any intelligent country friend unacquainted with the mysteries of photography, and with a few simple instructions he might bag some of the tit-bits of his district, and send them up by rail for you to develop at your leisure. In this way many an otherwise unattainable view might be secured for the stereographic scrap book; and, as with some collodions and dry processes over-exposure is hardly attainable — at any rate within the limits of reasonable attention to instructions— failures in this way need hardly be anticipated. Mr. Hockin's travelling cases are very compact in their arrangement, and contain cameras, slides, legs, printing frames, and all the materials an amateur is likely to require, whether *en route* or resident in country or town. To accompany these cases a dark tent has been recently perfected, to be used at home or abroad. It consists of a tray into which the bath packs; in front of it a portion is divisioned off for a series of square bottles that contain all chemicals required in the field; an aperture at the left hand side, with a pocket attached, receives the nitrate bath when at work; to the two sides are hinged open-railed frames both of *the same size* as the bottom tray; and on the third side, facing the operator, is hinged a solid board containing a yellow glass window, guarded by a shutter and a light-tight door which can be opened either to admit light or air, as occasion may require: these three slides mutually support each other when in use, as well as the black cloth that forms the tent. This frame-work is fixed on a tripod stand. When done with, first one frame is shut down, then the opposite one over it, and lastly the solid back closes down on all and protects everything. The tent then occupies the space of a moderate-sized carpet-bag.—An ingenious invention next claimed my attention, in the shape of a slide for instantaneous exposures, and applicable to single or twin lens cameras. For stereoscopic cameras two oblong brass plates, with two diamond-shaped apertures in each, overlap each other in such a manner that when in a state of rest both apertures in each plate are closed. The two plates glide over each other in a groove common to both, and lie on a base-board, pierced at one end with two circular openings, corresponding with two caps that fit over the lenses. At the other end of the base-board a small wheel works on a pinion; three spokes divide it into three parts. On rotating the wheel, by means of a projecting handle, two pins, placed diagonally at the circumference, begin to act upon slots in the end of each shutter, so that as the wheel is rotated the pins force the shutters apart in opposite directions, till at a certain point the apertures in each shutter coincide; but on continuing the rotation of the wheel till the handle has passed over one-third of the circumference, the two apertures are again closed, and a trigger falling into a notch retains the wheel in position till the operator is ready to expose the plate. To the left-hand side of the base-board one end of a vulcanised india-rubber spring band is fixed in a clamp screw or small vice; the other end is just drawn tight and fixed in another minature vice attached to the circumference of the wheel when at rest. On rotating the wheel the spring cord is extended, carried round with the wheel, and then lies in a groove in its circumference. On the operator wishing to expose the plate he releases the

trigger, the india-rubber spring re-acts and pulls the wheel back to its original position; of course the action of the shutters are then reversed, and at a certain point the two diamond-shaped apertures again correspond, and admit the rays of light emanating from the object to the two halves of the stereographic plate; but instantaneously passing over each other the light is cut off and the exposure completed. By clamping the spring cord at various points of tension a greater or less amount of rapidity of action is obtained. I obtained a copy of Mr. Hockin's recently-published *Practical Hints on Photography;* and from subsequent examination of its contents I can safely say it is worthy of its title, in face of the *ex-cathedra* (Dissenting !) objection of the "WEEKLY ANNIHILATOR" to its opening passage, and the attempt *(literally)* to "shut up" this useful little volume, wherein the reviewer might have opened up *untold* treasures if he had been photographer enough to recognise them when they came under his eye. But the *critique* looks very like a modern edition of the fox turning up his nose at grapes that were not within his power to digest.

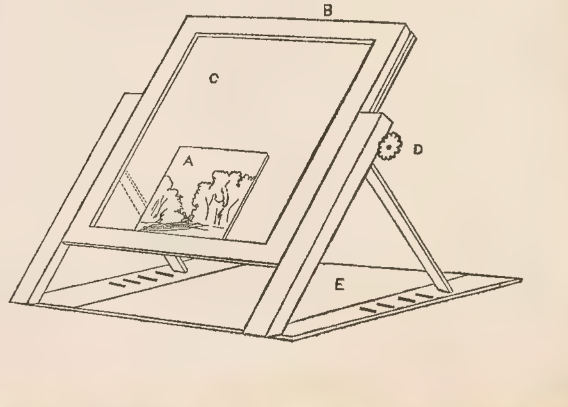
After leaving Hockin's I called at Messrs. Hopkin & Williams's, the manufacturing chemists, of New Cavendish Street, to obtain a supply of some pure chemicals I required, but I certainly did not expect to come across any photographic novelties; however I stumbled upon *a fact* which, "as found," according to Captain Cuttle's advice, I "make a note on." On expressing my surprise that they, as wholesale dealers, were charging a higher price for re-crystallised nitrate of silver than that at which this article had been offered to me by a retail house, it called forth the following explanation:—Whilst there was only an unimportant demand for the re-crystallised article they obtained their supply from other quarters; but lately they had reason for re-crystallising this salt in their own laboratory, and they were rather astonished at the result of their first and subsequent experiments, for, on re-crystallising 200 ounces of commercial nitrate of silver, they could only obtain 150 ounces suitable for photographic purposes, and the remaining fifty ounces, when obtained from the mother liquor, proved to be an almost unsaleable article. The mode of procedure and the results were as follows:—200 ounces of ordinary crystallised nitrate of silver, white and pure in aspect, were fused in a porcelain vessel at the lowest possible temperature, to avoid decomposition of the salt; the fused mass was then dissolved in distilled water, filtered, and two drachms of pure nitric acid added; for the solution, as first obtained, is alkaline, and would yield crystals quite dark in colour when dry, which, from their aspect, would be perfectly unsaleable. The amount of acid stated is the smallest quantity that will correct this defect. The solution is then gently evaporated, and, on cooling, yields crystals *rather small in size, very white*, but both *in tint* and *pearliness* of aspect *decidedly different in character* from the re-crystallised nitrate of silver we ordinarily obtain, as I can testify to from personal examination. After about 150 ounces of these pure crystals have been obtained a change occurs, the mother liquor begins to assume a greenish aspect, and to yield crystals of a tawny colour when dry; if it be then evaporated down to dryness the residue is distinctly green, and in parts impregnated with brown patches, and presents such an appearance that no photographer and few chemists or manufacturers would feel disposed to purchase it. On making a solution of this residue in distilled water, and adding excess of ammonia, the oxide was not precipitated and then re-dissolved, leaving a colourless solution (as would be the case with pure nitrate of silver), but the solution remained permanently dark coloured. It is thus evident that the commercial crystallised nitrate of silver is anything but the pure article it has been asserted to be; and the impurities it contains (though difficult to detect when testing on the small scale) are sufficient to account for many of the imperfections that have assailed the sensitised collodion film in the shape of marbling, fogging, &c.

If, in preparing re-crystallised nitrate of silver, it is necessary to sacrifice one-fourth of the ordinary crystallised salt employed in the operation, one can readily understand why it should be rather a costly product; but considering the moderate price at which it *has been* offered to the public, and the great difference in aspect between the assumed and *the known* genuine article, a strong suspicion arises that much of the "re-crystallised" salt sent into the market has been obtained by the simple operation of picking out the whiter, larger, and better-formed crystals from ordinary nitrate of silver. I am inclined to agree with a statement made one evening at the Society of Arts by a lecturer *On the Microscope*, that "there are few manufacturers who are not guilty of *adultery*," although the speaker immediately modified this assertion. I question whether the class thus stigmatised have modified their improper practices since that evening.

At Shew's, in Oxford Street, I was amused with the ingenuity displayed in the "getting-up" of some French stereographs, entitled "Satanic Slides," which represent ideal scenes of "high life below stairs;" such, for instance, as the arrival of a railway train from the realms above, filled with skeletons, who, from the expression of their fleshless visages, are evidently taking (shall I say) a *lively* interest in the *point de vue* of their destination, whilst a demon, of huge stature, in a green uniform of hair, acts as guard, *un diable rouge* as stoker, and *un gamin* perambulates the platform with *La Gazette d'Enfer* under his arm, and cries the latest news of these tropical regions. Then, again, there are such scenes as "*Les Vendages en Enfer*," "*Bal chez Satan*"—with a ghastly band in skeleton-suits playing an accompaniment to the dancers, but where the wind necessary for the proper performance of their instruments comes from is a question as difficult to solve as is that whether cherubims, as figured on ancient gravestones, are accustomed to sit on their heads or their tails—"*Marriage de Satan*," &c. In contrast with such agreeable views of this subject, there are renderings of "*Enfer*," "*Purgatoire*," together with *The Temptation of Saint Anthony*, &c. This series of stereographs is thoroughly French in conception, and will amuse those who delight in the *diablerie* of such scenes as are delineated by Retsch, of *The Witches Meeting on the Brocken*, *The Place of Execution*, &c., in his outline illustrations to "Faust." Their peculiarity, apart from the subjects selected, is the vigour and perfect ease that pervades the figures, and the expression thrown into the features of such unyielding models; whilst the composition of most of the groups is thoroughly artistic, and contrasts wonderfully with the namby-pamby figure-subjects that occupy too much space in our shop windows, and that carry on their face painful evidence of the models being thoroughly aware that they were going to be executed—stereographically.

Burke and Carter, the photographic mounters, Oxford Street, near Dean Street, have brought out a very neat form of passe-partout, made up with shagreen paper of various tints, and covered in with a very white glass that is supplied to them by Messrs. Chance, of Birmingham. If you want any of your photographs mounted in this style, I can recommend this pattern to your consideration, as I can also the portfolios constructed especially for photographs by Mr. Harvey, of 16, Rathbone Place. These have the flaps so made that they not only effectually keep out dust, but also completely protect the corners of the mounting boards from injury. Any photograph within may be placed under the guardianship of a good lock, the tongue of which forms a rest when the portfolio is open, so that the collection may be placed before the inspector as if inclined upon an easel, and the flaps are then folded back quite out of the way. This is not only a useful but an elegant contrivance, and durable withal, and is deserving of being more thoroughly known amongst photographers and artists.

Whilst in Rathbone Place I ordered an inclinable rack of Messrs. Winsor and Newton, which they brought out as a rest whereon to support glasses whilst being painted for magic-lantern views. *I* intend, however, to use mine as an easel for negatives that require "*touching*;" so I have had it made to take a plate twelve by ten. As the instrument takes less time to figure than describe, I give you a sketch of it, from which you will readily understand its construction, if I state that the frame B is filled up with a sheet of glass C, on which the negative A rests, and may be viewed as a transparency, whilst pin holes, &c., are being touched out; that the frame is adjusted higher or lower by means of a rack and pinion D; and that the instrument folds up flat when out of use.



As I cannot find time to tell you what came under my notice at the other houses I visited on this day, I must wait till I next write to you. I can only say that, on concluding my second day's voyage of discovery, I wended my way wearily towards the heart of the metropolis, determined to take "mine ease in mine inn," and that night I slept soundly, in spite of rumbling market carts assembling at early morning in the square below my window—in spite of the hubbub that characterises a London market meeting "in the morning early," so that, suddenly waking, one does not know whether a fire or a row is raging—in spite of a fellow-*inn*-mate, who came up with the early hot water, insisting on claiming my room door as his own till taken in tow by "boots"—and last, not least, in spite of endless dreams of binocular cameras on legs of inconceivable length, firing pistolgraphs at chromo-crystallised cats, flying at small boys just running under the wheels of a perambulating Hansom's tent, driven by a shabby man, who threatened to drink my health out of a patent collodion pourer, if I did'nt have my likeness taken for fourpence, on a plate prepared in a bath of recrystallised nitrate of silver, which in my helplessness I submitted to, when all his ghastly positive specimen portraits suddenly changed into "Satanic" skulls, who to my horror hooted the demon's chorus in *Roberto il Diavalo* at me during the whole operation, which was conducted by a very red devil, with a pig's head and a Cobra di capella tail, with a Harvey's patent portfolio under his arm, in which he evidently intended to lock up my shadow after the manner of Peter Schlemmel's—through all this I slept the sleep of the weary, and blessed my stars for the same, and cursed the chamber-maid *(horribile dictu)* when she called me at nine on the following morning. So, after a well appreciated breakfast, and doing my duty to my neighbour—that is to say, keeping my promise in writing to you,

I remain, Yours sincerely,

SIMEON HEADSMAN.

Meetings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A meeting of the above Society was held on the 1st instant, at the Rooms of the Literary and Philosophical Society, 36, George Street, Manchester,—Joseph Sidebotham, Esq., presiding.

Mr. Michael Noton was unanimously elected a member of the Society.

Mr. Samuel Cottam presented to the Society's portfolio six stereoscopic views in Oxford, mounted on one sheet, taken by himself on Dr. Hill Norris's dry collodion plates. He said he thought it might be interesting to the members to know that two of the plates had been in his possession about twelve months, and the results were equal to the others, which had only been recently purchased. He could not say the same of all the lot which were a year old; but that was probably owing to faults in exposure and development on his part. He was glad, then, to bear testimony to the keeping qualities of these plates.

Mr. A. Brothers exhibited a portrait on ivory, printed without nitrate of silver, and fixed without hypo. He said the process was at present a secret, and would remain so for three years, excepting to those who would pay £10.

Mr. Rogerson exhibited several very large pictures—23 by 18 in.—taken by the turpentine waxed-paper process, which were very much admired, being remarkably sharp, and full of half-tone and force.

Mr. Hooper presented four very beautiful waxed-paper pictures to the Society's portfolio, which were also greatly admired.

The Chairman said that the attention of the members would now be called to a correspondence which had taken place in reference to the alleged interference of Mr. J. L. Davies with the exhibition pictures in Peel Park. The Secretary would read that correspondence, and would also lay before the meeting a report on the subject, drawn up by a committee appointed by the council. He much regretted that so unpleasant a business should have occupied the attention of the members; but the question was really so important, and the charge it involved against one of their body so serious, that it was impossible to avoid the discussion. He trusted, however, that that evening would end it.

The Secretary then read the correspondence, which was very lengthy.

[Mr. Davies's letters, in which he denies the charge, appear in another column, as communicated by him, and do not, therefore, require insertion in this place.]

A communication from Mr. Plant, the Curator of the Museum, stated that Mr. Davies applied to him to have certain pictures removed and his own substituted; and that, in deference to his father's position, he had agreed to it, not thinking it a matter of any importance.

The following is an abstract of the report presented by the committee:—

That Mr. J. L. Davies used undue influence, in the first instance, to enter his pictures for exhibition without submitting them to the committee appointed by this Society, under whose sole responsibility and control the Exhibition room was placed by Mr. Plant.

That the committee having hung the pictures, Mr. Davies caused several of them to be taken down and replaced by his own.

That Mr. Davies has, in the hearing of members of this Society, boasted that he did so. Upon such conduct this committee would have advised the severest censure; but as Mr. Davies has tendered his resignation, its acceptance is recommended.

The report was then put and carried unanimously, and the Secretary instructed to strike Mr. Davies's name from the list of members.

The Chairman then called upon Mr. Mann to read the paper which he had promised. [See page 232.]

Numerous negatives and prints, by the process, were shown to the members, and were much admired.

The Chairman: The paper which we have just heard read is one that must not only have taken us by surprise, but must have afforded us a field for thought and for experiment of a most interesting and profitable character. We have heard a statement of facts, and have seen them corroborated by results which are entirely new to us. The gentlemen who have pursued these experiments have most modestly declined putting forward a claim to a completed process. They state that what they have done must be taken only as something from which more may arise; but I think that no one can look at the negatives on the table without being persuaded that the new method is capable of producing most beautiful results, even in its present state, and that we may reasonably hope for uniformity of action. If there were no other advantage attendant upon this process over the ordinary collodio-albumen, the banishment of the aceto-nitrate bath would effect a most important improvement. The ever uncertain condition of that agent is a great evil, besides the additional expense and trouble it involves. Having been favoured with a description of this process some days since, I prepared two plates, and here are the negatives taken upon them. One of these, before the washing (or as it must now be called sensitising), was placed against a window, in full sunshine, for two or three hours—a test that proves most decidedly the assertion of the discoverers, that in the first stage the prepared surface is quite insensitive to light, and that the washing in water imparts that quality. I notice, however, one remarkable fact, that the picture appears to pass through the albumen, for it may be rubbed off, as you see, without disturbing the film.

A Member: Is not the albumen removed by the washing?

The Chairman: No, it can be seen that it is not so, the reason being that the albumen is coagulated, but perhaps not perfectly, by the heat with which it is dried.

Mr. Mann: The Chairman has observed that the image may be removed by rubbing without disturbing the film: I have not found it to be so on the plates that I have used, and I submit that the effect is due to a certain description of collodion.

Mr. Cottam: Here are two negatives taken by this process; the plates were prepared under difficulties, but it will be seen that the defects do not belong to the process.

Mr. Mabley: I have seen the progress of the experiments which have been described to us this evening, and I must own that I was at first sceptical as to the results, but my doubts are in great part removed, and I think, as we must all hope, that a great improvement in the dry processes is in store for us. The facts, for such they are, which have been laid before us, even those in reference to the use of a chloride in the albumen, involve something perfectly new to us. It has been known for some time now that a plate was not destroyed in sensitiveness by the application of a chloride; but we did not know, and this it is which gives the process one great value, that the plate was insensitive while the chloride remained upon it, but might be rendered sensitive simply by washing in water. That is a most important and novel fact, but the treatment of a plate with an iodide in a similar manner is more surprising still; and I wish particularly to call attention to the fact that *paper* treated in this manner possesses quite an opposite quality. Paper prepared for the calotype is furnished, with the exception of the collodion and albumen, with just the same film of iodide of silver, for it has first of all an excess of the potassium salt which is removed by washing: if it obeyed the same law as these plates, it should by that washing be made sensitive, but it is well known that it may be submitted to any amount of light without injury.

Mr. Wardley: Papers so prepared are improved by the action of light, and I think we must assume that, in the process now brought before us, the albumen plays an important part; but that is a matter which must remain for investigation. There is one feature in the process we are now considering which deserves particular attention: it is the facility with which plates may be sensitised upon a journey. It is probable that this may not be of importance on keeping considerations; but there will be this advantage, that a sensitive surface, free from intrusive impurities, will be obtained, and those who are in the habit of travelling with photographic plates will appreciate this. I must differ from Mr. Mann in his statement that blisters may not be expected. I think that the film will be quite as likely to blister by treatment with water as with nitrate of silver.

Mr. Petschler: Mr. Mann's plates have been free from blisters, but I cannot say that of some of mine. They have assumed, however, a different character to those upon collodio-albumen plates; they have entirely disappeared when the film is dry, and do not again rise under development.

A Member: Will Mr. Petschler be kind enough to inform us how he was led to this discovery?

Mr. Petschler: It was in this manner:—I had for some time been experimenting with chlorides in the collodio-albumen process, and on one occasion dipped a plate into the bath of aceto-nitrate, which did not contain sufficient solution to cover it. On developing this picture I found that the portion which had not been covered by nitrate of silver developed much more quickly, and with greater intensity, than that which had been covered.

A Member: It was an accident, then.

Mr. Mabley: But followed out with much ingenuity.

Mr. Petschler: This led me to consider that as the part uncovered with silver solution should have been insensitive, according to received opinions, the acquisition of sensitiveness must have arisen from the removal of the salts from the albumen by the ordinary washing which the plate was subsequently submitted to; and that proved to be the case. After that it was necessary to discover which was the better salt, the iodide or the chloride, when used as Mr. Mann has described, and the latter, after repeated experiments, we adopted. Our time, however, having been insufficient for full experiments, we do not say that the iodide may not be found equally efficient.

The Chairman: There is an advantage in developing these plates which is very striking: you cannot discolour them by the solution. One of these I purposely attempted to stain by using pyrogallic acid completely black; but it is fully as clear and bright as the other, which was carefully developed with a clear solution.

A Member: Will Mr. Mann say what amount of washing is required to remove the salts from the albumen?

Mr. Mann: The plan I have adopted is to wash the plates under a tap for two or three minutes, but I do not say that washing to that extent is required.

The Chairman: My stereoscopic plates were merely washed in a dish containing a small quantity of water.

Mr. Mabley: Our attention has been called to a negative, one-half of which was submitted to a second sensitising, as in the Taupenot process, and the other half simply washed in water, and it is remarked that the latter is more fully developed. I submit that this is not of necessity due to inferior sensitiveness in the former, but may arise from the fact that the albumen on the portion treated with nitrate of silver is completely coagulated, and is therefore less pervious to the developing solution. I think it would be found that both portions could be equally brought out by prolonged development, although, perhaps, not without that muddy deposit which we frequently get in collodio-albumen: and therein lies a great advantage of this process.

A Member: Will Mr. Petschler be good enough to give the particulars of exposure of one of the negatives on the table?

Mr. Petschler: This negative, a mixed landscape, which it is agreed is fully exposed, was taken at half-past five in the evening in a good light. The lens was seventeen inches focus, with half-inch stop; the exposure twenty minutes.

The Chairman: Gentlemen, I think a vote of thanks is due to Messrs. Petschler and Mann for the paper given us this evening. I am sure we are greatly indebted to them for the matter they have brought before us, and I would suggest that during the next month all those who have the opportunity should follow up this process, and that the subject should be resumed at our next meeting.

Mr. Mabley: The facts which have been brought before us this evening add materially, I believe, to our photographic store. I am not acquainted with anything which has been given to our art for a long period which equals them in novelty and in prospect of useful application; and we may now hope that the editor of a certain photographic publication may discover that the Manchester Photographic Society is still in existence.

A vote of thanks was then passed by acclamation to Messrs. Mann and Petschler, and also to the Chairman.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

[In consequence of the large amount of space devoted to the reports on the Solar Eclipse, we are compelled to postpone the publication of the continuation of this article, and also some "Answers to Correspondents," till our next number.]

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

E. M. Tyrrell, Williamsburgh, L. I., New York.—There is much promise in your colouring: it is clean, bright, and natural; and your touch is of the right kind, but the drapery and hair are *very* badly executed. Hair is always transparent where it nears the flesh, partaking in its hues of the flesh-shadow colours, broken and softened with greys: it is *never* of one uniform tone of black, but owing to its glossy surface displays all the various modifications of colour arising therefrom. Now your hair comes to the flesh as opaque and black as the pure pigment can make it, instead of graduating from fleshy greys into the local colour softly and insensibly. Take a guide, and study to preserve in your coloured *fac-simile* all the softness of the photograph, remembering that the edges of the hair and flesh must so partake of each other's colour as to indicate the former's natural character. The drapery in your picture is one flat, opaque mass of black pigment, conveying no idea of anything but paint. Where the lights fall and where the shadows rest are of the same colour; the folds are all concealed; texture is completely destroyed, and such parts of the picture as are tolerably well done quite destroyed. I am gratified to know that I have pupils in the young country so closely connected with dear old England, but so very far away.

J. B., Rosalind, and one other pupil, are informed that their productions will be noticed in our next—the author, in consequence of absence from home, not having seen their specimens.

Foreign Correspondence.

Paris, August 11, 1860.

The photographic results obtained by the members of the French commission sent into Spain to observe the eclipse of the 18th of June are unfortunately very small. I will give you what MM. Le Verier and Léon Foucault say in the official report transmitted by those gentlemen to the Minister of Public Instruction.

"We set up equatorically an ordinary camera, provided with a double objective, with a wide opening and a short focus, and throwing upon the ground glass a solar image of great brilliancy. The apparatus was furnished with a finder, and was moved with the hand by means of a screw, so that, by keeping the sun upon the point where the threads of the eye-glass cross, we were enabled to maintain the image nearly motionless upon the screen of the camera. It was then merely necessary to substitute, for the ground glass, collodionised glass plates recently rendered sensitive, and to leave them exposed for a longer or shorter time to the action of the real image of the eclipsed luminary.

"Immediately after the disappearance of the last ray of direct light, the first plate was put into the focus, and exposed during ten seconds. It was then succeeded by another plate, which remained twenty seconds, and by a third sixty seconds. On leaving the bath, the three plates were treated with sulphate of iron and cyanide of potassium, in order to obtain *direct positives.* In the hurry of the manœuvres, the frame containing the first plate was displaced when the objective was already uncovered; several images were thus accidentally produced after a very short exposure, thereby bringing into the discussion valuable and unexpected elements. In some, on the three plates, six distinct images were obtained, of which three were formed after the exposure, which could not have exceeded a quarter of a second, while the three others are the results of an exposure of ten, twenty, and sixty seconds respectively.

"The three images formed in the fraction of a second, the moment after the sun's disappearance, do not offer a complete representation of the halo: they are reduced to the circumference of a circle surrounding the dark disc, and present variations of intensity which, three times repeated, cannot be attributed to the accident of manipulation. On the side on which interior contact had just taken place this circular outline shows increased intensity; besides, on the three images may be observed similarly situated irregularities, which seem to be an exaggerated representation of the irregularities of the lunar outline. When the image is again placed in the real position of the heavenly bodies, it is seen that among these denticulations there are two principal and contiguous ones at the lower and eastern extremity of a diameter of forty-five degrees of inclination.

"The other three pictures give to the halo an extension which increases with the duration of the exposure. This halo is shaded off outwards from the sun, and is lost, without line of demarcation, in the general tint representing the sky. In the picture which underwent the exposure of sixty seconds, the halo extends visibly to a distance equal to three times the radius of the central disc. But, in particular directions, the halo offers in its intensity positive and negative variations, which resemble the rays of a glory; one of these variations, more clearly marked than the others, is prolonged beyond the rest of the halo, and seems to emanate precisely from the point occupied by the denticulations already mentioned.

"Such are the facts resulting from an experiment in which the sole object proposed was the appreciation of the photogenic activity of the halo upon wet collodion. The agreement to be found in the six pictures furnishes positive elements for the discussion of the nature of the halo, which I hope to turn to account."

We thus see that the most useful data acquired by the observers are precisely those that were due to an accident — to the unintentional shifting of the apparatus, which affords us another example of the truth of the consolatory old proverb:—*A quelque chose malheur est bon.* With the exception of MM. Vernier, Son (of Belfort), and Goulier, I do not know that our French photographers have much occupied themselves with the interesting phenomenon. I have not seen M. Goulier's pictures, but M. Vernier has sent me three, which, although of small size, give a very exact

image of the sun at three different periods of the eclipse. They are all surrounded by a halo, the cause of which M. Verrier seeks in the phenomenon itself, and which, according to the adepts in photography, is to be explained by the simple fact that the operator made use of an objective with too large an opening. This shows how delicate such experiments are, and what care is necessary if we wish to arrive at exact conclusions.

Mons. M. A. Gaudin has just published a dry collodion process, to which I would call the attention of your readers. The collodionised glass, after being well washed in water on leaving the silver bath, is left in a water bath, to which have been added a few thousandth parts of alkaline, chloride, or iodide. In this manner the nitrate of silver is entirely destroyed, and forms a corresponding portion of chloride or iodide of silver, which combines with the original sensitive pellicle. Having again been washed with common water, and then with distilled water, the plates are put to dry slowly in a suitable place, away from the light and the dust.

If the presence of the silver bath is useless during the exposure, its presence, according to M. Gaudin, is indispensable for the development of the image; for, before we pour the developing solution upon the glass, this latter must be first dipped into water and then into the silver bath, as if it had not already been sensitised.

Starting from this same principle, our friend proposes, as a means of preserving positive papers, to dip the sensitised sheets into salted water, on taking them from the silver bath. One or two per cent. will be a sufficient proportion. After some hours' stay in this water, the sheets are rinsed in common water, and then put to dry. You see that the process proposed by M. Gaudin is as simple as it is feasible. ERNEST LACAN.

New Books.

Shepherd & Co.'s "Universal" Guide to Photography, by a Practical Photographer. Third Edition.—London: E. Marlborough & Co., 4, Ave Maria Lane; Shepherd & Co., 97, Farringdon Street, E. C.

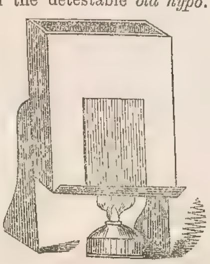
This is one of the pamphlets, of which the name is "legion," intended to indoctrinate the unlearned into the mysteries of the black art, and, at the same time, impress them with a decided conviction that the best possible place for them to procure apparatus and chemicals is at the establishment of the publishers. This is all reasonable enough; it is not to be expected that any one carries on business out of pure philanthropy: moreover, as a rule, there is really very much information to be gained from the generality of pamphlets like that now before us, and to which it forms no exception in this particular. But there is somewhat in it to which we object, and for which little excuse can be offered, seeing that it is a *third* edition. We notice no less than three palpable typical errors in one page, and that one only the seventh in the book, the word "*foci*" being twice used for "*focus*," and "*course*" for "*cause*."

Our attention was, however, specially drawn to those blunders by the following very extraordinary assertions in that page and the next, which we quote, viz.:—"It is common to hear of a lens being slow or quick in its action; this is *purely accidental*," &c. Again:—"So that a lens of twelve inches focus, covering eight inches square, is not half so quick in action as a lens of six inches focus, covering four inches square, for the amount of light *reflected* from the same object *is four times as much in one case as in the other*." (!) The italics in both passages are our own.

We strongly recommend the publisher to expunge the passages above quoted, for as manufactures of lenses they may find them injurious; because, if people judge of their practical knowledge of lens constructing by their theoretical knowledge of optics, they will probably be held in less estimation than they deserve.

Not a word is said about the respective diameters of the lenses, though, no doubt, the writer intended his observations to apply to those of equal diameter; and the assertion relative to the amount of light *reflected* from the object is simply—nonsense.

In the formulæ we notice a tendency to very unnecessary complication, and, as a rule, the amount of nitric acid directed is exorbitant. We are glad to perceive, however, that in the printing and toning formulæ Maxwell Lyte's method finds a place, though the detestable *old hypo.* bath is also included, and even takes precedence thereof.



When treating of the Taupenot process, there is a capital suggestion for drying the plates, after being albumenised. It consists of a tin vessel, made in the form of an ordinary dipping bath, but a little raised from the table, and furnished externally with a ledge, upon which the plates can be rested on end. The bath is filled, when in use, with boiling water; and the water is kept boiling by a spirit lamp or gas flame underneath. The annexed cut shows this application, and we presume they are to be procured of Messrs. Shepherd and Co.

Correspondence.

THE EXHIBITION OF PHOTOGRAPHS AT SALFORD.

To the Editor.

Sir,—I trust you will do me the justice to publish fully, in your Journal of August 1st, the enclosed letters, in direct contradiction of the scurrilous attack and calumniating charge made upon me through the medium of your Journal of 16th July.—I am, yours, &c.,

Manchester, July 17, 1860. JNO. L. DAVIES.

TO THE SECRETARY OF THE PHOTOGRAPHIC SOCIETY.

Sir,—In refutation of the very extraordinary charge of unwarrantable allegation imputed to me in the "resolution" your Society thought proper to adopt, in my absence, at the last meeting, I beg to state that all arrangements and subsequent alterations, both in the "hanging" and reception of the several works of art at the Exhibition of the Salford Royal Museum and Library (including the photographs), were conducted, as I am instructed, by the gentlemen forming the committee elected for such purpose, of whom the Mayor of Salford was one; and from such committee the curator, Mr. Plant, would doubtlessly receive *final* instructions, which were decided upon after the "private view." I may add that the pictures which have formed the subject of the groundless report you allude to were solicited by the chairman and others of the Museum and Library Committee some considerable time before the opinion and co-operation of your Society was sought, and frames for their reception were furnished to me by those gentlemen, and, I presume, they did not deem it incumbent upon them to ask the "sanction" of a contributing Society as to where such pictures might be hung. In conclusion, I feel justified in requesting that you will place my reply to this calumnious imputation before your committee, and that you will render it the same amount of publicity as the charge has received.—I am, yours truly, JNO. L. DAVIES.

4, *St. Ann's Square, July* 17, 1860.

P.S.—I enclose copy of a letter from the Mayor of Salford corroborating the aforesaid statement.

[COPY.]

Dear Sir,—We beg to state that the arrangement committee of the Royal Museum, Peel Park, applied to you for the loan of some of your excellent photographs some time before the Photographic Society promised to be contributors to the Exhibition, and felt greatly obliged by your then promising to contribute.

With regard to the "hanging" of the photographs originally, or any alterations made subsequent to the private view, we entirely acquit you of all blame, and regret that the Photographic Society should have brought the charge they have done against you.

Had the secretary inquired from the arrangement committee *before* the resolutions were published, we think he would not have blamed you in the matter.

We remain, dear Sir, yours respectfully,

(Signed) J. W. WESTON, Mayor,

July 17, 1860. And Member of the Arrangement Committee.

A PHOTOGRAPHIC MIRACLE!

To the Editor.

Sir,—Having been for some time past a looker-on at photographic operations, I have just commenced the practice of the art, and have gone to some considerable expense in procuring a proper outfit of apparatus and chemicals. I was just beginning to enjoy my work, having mastered most of my preliminary difficulties, when yesterday a photographic friend called on me, and showed me an announcement in a number of a photographic contemporary, to the effect that a French gentleman, whose name I forget, had invented a new *photographic ink* to supersede the use of nitrate of silver, and that another of his countrymen had, in consequence of seeing Woodward's enlarging camera, invented an apparatus by which an amateur, who is almost ignorant of the art, may be converted into a skilled photographer with the aid of an hour's instruction from an adept in its use.

I fear that I have been rather too fast in procuring my outfit, and was not a little mortified to find how much better I might have fared by waiting a little.

On thinking matters over, however, it has occurred to me that possibly the author of the notice in question may have been a little too fast; so I have determined to write to you for an opinion, feeling sure that you will at least give me a candid one.—I am, yours, &c.,

P. WARBECK.

Kensington Gore.

[You have no reason to be dissatisfied; the conductor of our *weakly* contemporary must have been very hard up for a wonder to make such a blaze about a trifle. As usual, anything that comes from the other side of the channel is with him a marvel; while the same thing, or a better one, under his very nose, if brought out by an Englishman, is either ignored or reckoned of no value.

We had a good laugh over the paragraph to which you allude before receiving your note. With regard to the first item, the *authority* quoted is, we believe, a *very pleasant old lady of the male sex*, who so frequently commits errors in judgment that we attach no importance whatever to his opinion on the matter either one way or other. The new *ink* may or may not be of great value: we hope it is. It is very probable that it may be, as its introducer is a skilful photographer.

The second part of the announcement is, however, pre-eminently absurd: there is no novelty whatever in the idea of enlargement; and as regards the camera mentioned, reference to our columns will show that M. Bertsch holds it in quite as much disesteem as we do. M. Bertsch, of whom we know nothing save by his writings, is evidently a man of scientific attainments; and though we are not disposed to take any alleged fact in science for granted without examination, we should hesitate long before concluding him to be in error in his own speciality. The automatic camera proposed by him is, however, not quite so new as he supposes: it is only a development of what has already been done by

Mr. Skaife, in what he calls his *pistolgraph* (anathematised be the name!), of which you may readily satisfy yourself by a visit to his establishment in Baker Street.

M. Bertsch's arrangement will, however, be a further development of the idea, and a good one, too, judging from his published intentions, and his enlarging arrangements are worth fifty of Woodward's.—Ed.]

WAVY LINES IN FOTHERGILL PLATES.

To the Editor.

Sir,—Would you kindly look at the enclosed stereograph and inform me what the cause of the marks you see across it in every direction can be. It is from a "Fothergill" plate of my own preparation. I am an amateur, and have followed this process for three years, during which time I have taken a great many pictures, most of them good enough to satisfy an amateur; but this year I have met *with nothing but failures.* I have tried new baths, five or six different solutions; prepared about fifty plates, with slight variations in each, such as *albumen* of *different* strengths, *much and little washing, &c.*—in fact *everything I can think of;* but the plates come out covered with *thin wavy lines* in all directions. I cannot account for them myself. I have inquired of many professional operators and they assign different reasons, and I have acted on their suggestions, but with no better result. I am now about to give up the process in disgust; but before doing so, I have been advised to write to you. If you will be kind enough to give me an answer as to the cause of these marks on the picture, in the next number of your Journal, which I take, I shall feel greatly obliged. I enclose my card.

I am, yours, &c., J. W.

P.S.—I generally use Keene's or Horne and Thornthwaite's collodion; am most particular about cleanliness of plates and preparation, having practised photography the last seven years.

[We have no doubt about the cause of your wavy lines: they arise from an error in manipulation, although you do not describe your *modus operandi.* In adding albumen to your diluted nitrate of silver solution on the plate, sooner or later a curdy precipitate is formed, and parts of this adhere very tenaciously to the film, but can generally be removed by letting fall a good stream of water on to the plate, and inclining it alternately in various directions. No amount of mere immersion is of any use; you must let the water fall on the plate, and that from some height.

We recommend you to proceed as follows:—After sensitising and diluting the free nitrate, *in your own way*, pour on about half an ounce of *dilute albumen* for a stereographic-sized plate, pouring it along the edge, and allowing it to flow evenly across to the opposite side, and let about half of it run off at the side, allowing the remainder to flow back and remain on the plate for about one minute; then wash off by a stream of water, holding it under the tap. You cannot wash too freely.

Make your dilute albumen by adding one ounce of white of egg to three ounces of water, and dissolve therein six grains of citrate or phosphate of soda.

Follow this plan, and we are convinced you will no longer be troubled with the wavy lines, provided that you do not allow any accumulation of water at the lower angle when drying.

After washing under the tap, it is better just to flow over the plate, for a final wash, about half an ounce of *distilled* water.

Let us hear of your success.—Ed.]

THE PICTURESQUE FOR PHOTOGRAPHERS.

To the Editor.

Sir,—It would much oblige myself personally, and doubtless many other amateurs, if you would publish a list of the most picturesque places, suitable for the photographer, around London—say within thirty or forty miles, or an easy railway distance.

Such a list would be a great boon, and it should point out the trains or conveyances to go by, and how to proceed afterwards; that is, the shortest routes to the "nice spots," &c., &c.

I am, yours, &c., DRY PROCESS.

P.S.—Perhaps you can help us in the forthcoming number, as we have not now many spare Saturdays to depend upon. Your excellent correspondents, Messrs. Hannaford and Wall, will probably assist you with their knowledge and experience.—D. P.

[It is singular that before receiving your note we have replied to another correspondent to a somewhat similar question—(see "Answers to Correspondents"); and for the purpose desired by him we recommended a visit to Sevenoaks, in Kent. Access by *Mid Kent* Railway, from London Bridge to Bromley Station; thence by omnibus, which meets two of the trains daily.

Reigate is another fertile spot for the photographer, where abundance of admirable subjects can be found. You might work in this neighbourhood for months. Colchester, again, presents many nice landscape and rural subjects. We shall be happy to publish any similar hints from our correspondents.—Ed.]

FOTHERGILL PROCESS.

To the Editor.

Sir,—In the preparation of dry plates by the Fothergill process, what precaution is necessary to prevent water markings? Would a longer time in the diluting water and more movement be of benefit?—that is, after sensitising, putting it into the diluting water, and continue moving it up and down for some five minutes instead of three minutes, and afterwards coating with dilute albumen, containing a solution of chloride of ammonium.—I am, yours, &c., W. G. T.

[It is not a question of *time* but of movement of the washing water. We generally use about *an ounce* of distilled water to a plate ten by eight inches, which we pour on and keep in motion until it will pour on and off without any appearance of streakiness, which will happen in from two to three minutes. We then apply dilute albumen—one part to three of water—containing about two grains of citrate or phosphate of soda to each ounce of mixture: leave this on for three or four minutes, and then wash very copiously. We never experience water marks.—Ed.]

SUGGESTION FOR A NEW PHOTOGRAPHIC INK.

To the Editor.

Sir,—There is a circumstance that has attracted my attention relative to photography that may be found useful; but not having time or a sufficient knowledge of chemistry to prosecute it, I have ventured to solicit your insertion of the few remarks I have to make in your Journal, in the hope that they may meet the eye of some person who has the time and knowledge required.

What I have observed is this:—That the juice of new potatoes produces a precisely similar stain on the skin as that of nitrate of silver. Whether the light operates on it or not I cannot say, but it is removed by similar acids. Trusting that it may be found useful in photography,

I am, yours, &c., JOSEPH STUBBS.

Liverpool, August 2, 1860.

[We do not expect to find that light plays any part in the phenomenon; but it is easily tried.—Ed.]

ANSWERS TO CORRESPONDENTS.

Erratum.—In page 241, outside column, 31st line from foot, for "slides" *read* "sides."

J. L.—Declined with thanks.

Sold.—Not so; you will find it correct.

Well-wisher and Fk. Anslow.—Thanks for your good opinion.

Misty.—This correspondent's letter shall appear in our next number.

A Clerical Amateur.—Too late for insertion in this number; shall appear in our next.

A. M.—Your specimens are not of sufficient merit to permit us to notice them: they are all more or less faulty.

L. Stansbury.—It is highly probable that you may obtain the subjects for which you ask by application to the officers of the Department of Science and Art, at the South Kensington Museum.

F. Baker.—The person named deals in second-hand photographic apparatus, and we believe him to be honest and worthy of dependence. We think you will be quite safe in his hands.

Subscriber.—See replies to "W. G. T." and "J. W." Protect your gas-burner by yellow calico and you may use plenty of light to work by. Your exposure may be from five to fifteen minutes, according to circumstances.

Solitary One.—Take to the camera, by all means. Join one of the metropolitan societies (that nearest to your residence in preference), and we can safely prophesy that ere long your present signature will be a misnomer.

Anti-Humbug.—Your signature is inappropriate: you do not object to be "humbugged," but to the operation being clumsily performed, that is, if we understand your letter aright. Your change appears to us to be "from the frying pan into the fire."

A Curate.—See reply to "A Clerical Amateur." Try a *thin* collodion, and wash with a weak solution of bromide of potassium, say one grain to the ounce, then with rain water, and dry without any preservative. Before developing, put the plate into a bath of nitrate of silver, ten grains to the ounce, and develop with proto-*nitrate* of iron.

A Young Photographer.—Questions 1, 2, and 3, have been so repeatedly answered by us that we must refer you to our back numbers, or to any good manual, of which there are plenty to be had for the cost of one shilling.

4. Your remedy for a "fog"-producing bath was diametrically opposed to what it should have been: a drop or two of dilute nitric acid will most likely restore it.

Muddle-headed.—We cannot see what there is to confuse you: coat your plate—sensitise it—expose in the camera—develop the image—wash and remove the sensitive coating, *i. e.*, fix—well wash and dry—six operations always performed in the same order. If you cannot remember these, how can you expect to take a picture? Study your Manual well before you begin to work, and if you will begin by printing, instead of trying to take negatives, you will get on all the faster.

S. W. L.—1. Your albumen can be used without filtering, if you allow it to stand and pour off gently only about half of the upper portion for use. Your filtering paper has been too dense; procure either some Swedish filtering paper or some of the circular, grey, French filters. See replies to "Subscriber," "W. G. T.," and "J. W."—2. Your collodion wants thinning with ether.—3. Your questions on colouring shall be forwarded to Mr. Wall.

Thomas Marlet.—You will find some excellent studies of trees in Knole Park, at Sevenoaks, in Kent, where you may very profitably spend three or four days with your camera. You will find the "Crown" a very comfortable hostlery, with a nice old fashioned garden, in which to take your ease after the fatigue of the day. There is also a very attractive panoramic view to be obtained near to one of the entrances to the Park, on the road to Tunbridge, and there are also many nice rustic "bits" to be had in all directions. We recently spent a couple of days there (Saturday and Sunday), and were much taken with its photographable (!) capabilities.

A Highland Laddie.—Your lens seems to be a very fair one for portraits, but you could get better results by a proper landscape lens for landscape purposes. A whole-plate lens for portraits would produce *larger*, but not necessarily better pictures—probably not so good. Of those you have named we prefer No. 3, but we could indicate better still. We do *not* recommend you to procure an orthoscopic lens for what you require.—Carbonate of soda will do. The woolly substance is a fungoid growth. Citric acid should be kept dissolved; but you may filter out the fungus, and the solution left can be used. Send a directed envelope, and we will let you know what to do about your landscape work.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 125, Vol. VII.—SEPTEMBER 1, 1860.

Most of our readers are sufficiently well aware that we have not unfrequently had the misfortune to differ in opinion with Mr. Sutton, of Jersey, upon various matters of interest to photographers; and as we have not shrunk from expressing our dissent when called upon to do so, neither do we avoid mentioning our hearty concurrence with respect to a matter towards which he has been recently directing the attention of his friends—and we do so with more alacrity owing to the rarity of the occurrence of our agreement.

The subject to which we make allusion is primarily that of taking *negatives* upon albumenised paper, and incidentally relative to albumenised paper for positives. As regards negatives upon albumenised paper, the first suggestion for its application emanated from Mr. Mayall about four years ago, and we have some recollection of that gentleman having promised to read a paper upon the subject before the Photographic Society; but, like many other "good intentions," we presume it only formed one of the paving stones said to exist in a locality that shall be nameless. Whether any experiments were carried out by him in this direction or not we are unaware; but the practicability of the plan was clearly demonstrated about twelve months ago by Dr. Maddox, an account of whose operations appeared in this Journal at the time specified. There were, however, certain manipulatory difficulties which still remained to be conquered, more particularly that of floating the prepared paper upon the sensitising solution, in consequence of the stiff and unyielding nature of it after the treatment that it underwent.

The object proposed for attainment by the employment of albumenised paper for negatives, is greater delicacy of definition than can be accomplished upon plain paper, just as we find positive proofs upon the former to possess more definition and transparency in the shadows than those upon the latter; and this effect is probably owing to the impression being kept rigidly to the surface instead of being allowed to sink partially into the fabric of the paper. This principle is one that we advocated for positive prints several years back, in a paper read before the Photographic Society, and which was totally opposed to the views then entertained by Mr. Sutton, but which views more extended experience has doubtless caused him to abandon. The principal object, however, at present in his speculations is the employment of paper for negatives, so as to obtain a maximum of sharpness of detail in order that he may apply it to work with his panoramic lens instead of glass; and a very legitimate object it appears to be, because by its substitution he not only gets rid of the great expense and difficulties of manipulation attendant upon the use of curved glasses, but it also enables an operator to focus to some extent the different parts of a subject as may be requisite, in the same manner as was done by M. Martens with his panoramic camera and revolving lens. Although we believe that the inventor of the panoramic lens maintains that there are no manipulatory difficulties in the use of curved glasses, and no need of focussing, we cannot concur in any such opinion; and we think he has done wisely in pointing out a way by which those who hold with us in this matter may avoid what they regard as grave inconveniences.

Of course it must be evident to every photographer that the substitution of paper for glass in the negative would be a very great boon to all, provided that nothing of importance were sacrificed in order to render the former available. We have strong hopes that for a very extensive range of subjects this may ere long be possible; and our advocacy of the attempt to bring about the accomplishment of this desideratum is without reference to the employment of any particular kind of lens.

There is another point upon which our opinion with reference to this subject coincides very fairly with that of Mr. Sutton, we mean with regard to the kind of paper most applicable for the purpose. We have made very many experiments with almost every kind of paper at all likely to be serviceable upon which we could lay our hands, and certainly that which we preferred upon all accounts was of Hollingworth's manufacture. We have not found any material difference between the thick and the thin varieties, but for negatives it is probable that the latter would be preferable.

We now come to the consideration of the best means of keeping the coating of albumen strictly to the surface of the paper, and rendering the paper itself as far as possible impermeable to aqueous solutions. In Dr. Maddox's experiments this object was sought to be accomplished to some extent by impregnating the paper with wax, or by the substance known as vegetable wax (an importation from Japan), in either case the wax being dissolved in paraffin oil, or in the analagous solvent known as Belmontine. Besides rendering the paper more or less impervious, it also subserved the purpose of increasing its transparency; but inasmuch as it has a tendency to unite more or less with the chemicals employed, and as paper impregnated therewith ceases to be useful as a basis for a positive proof, it would be advisable to adopt, if possible, some other *water-proofing* material, if we may so define it; and that which occurs to us as being worthy a trial is *plain collodion*, applied to both sides of the paper before the coating of albumen is laid on. Every photographer knows how difficult, not to say impossible, a matter it is to make an aqueous solution penetrate a film of dry collodion, provided that no "preservative" material has been superadded prior to desiccation: it is therefore by no means improbable that by properly applying this material the paper may be made sufficiently impervious, not only to prevent the sinking in of the albumen, but also to prevent the penetration of the various chemicals, and thus avoid their being stored up, as it were, in the fabric of the paper as in a sponge, to act and react upon one another, and thus ultimately, if not immediately, compass the destruction of the positive or negative impression, as the case may be. We also presume that under such circumstances the necessary amount of washing subsequent to fixation might very materially be curtailed with safety.

It may be objected that the suggestion which we have thrown out is a very crude one, and that we ought not to have made it

without having first of all tested its practicability. We admit that this would have been the better course, but, unfortunately, it is at present impracticable for us to do so, our time being so fully occupied in other directions; and we are not willing to lay aside for an indefinite time an idea which we think offers a fair prospect of solving a problem of particular interest at the present time, and which some of our more fortunate photographic brethren may have opportunities of putting practically to the proof—our object being neither honour or profit, but simply a desire to lend a helping hand in working out what we consider may prove to be an advantageous reform.

Since writing the preceding we find that this subject has been still further considered by the same gentleman who brought it forward, and that one of the drawbacks supposed to exist with reference to the use of albumenised paper for negatives is the imagined comparative rapidity of its deterioration after being sensitised, as compared with that of plain or waxed paper. But here again we believe we can suggest a remedy without reduction of sensitiveness; for if after removal from the nitrate bath the papers, instead of being washed in plain water only, are first treated with a weak solution of citrate or phosphate of soda, the conditions will probably be identical with those in which we find dry collodionised plates prepared by the Fothergill process, and on which we have taken satisfactory impressions after their having been sensitised for upwards of ten months. We see no reason why paper treated in this way should not, if properly secured against atmospheric action and that of light, keep in working order for one or two months at least.

The substitution of paper for glass as the support for large negatives would be a boon of such enormous magnitude to photographers, that we consider any attempt to accomplish it satisfactorily to be deserving of encouragement, and the complete solution of the problem worth almost any amount of trouble.

We described in our last, in reply to several correspondents, the particular method in which we have been in the habit of working the Fothergill process; and it is not a little singular that the estimation in which we hold that very convenient method of preparing dry plates should have been justified by the labours of Messrs. Petschler and Mann, the details of which we published at the same time. Any one who will take the trouble of comparing the two modes of operation—viz., that described by the Manchester experts and our directions for the Fothergill plates—cannot fail to be satisfied that the *principle* involved is almost identical in both; for, on reperusal of the paper, we have come to the conclusion that the cause assigned by Messrs. Petschler and Mann for the insensitiveness to light before the final washing of the plates, prepared by their very excellent method, is the correct one, though the reason for its being so is not pointed out. To prevent the possibility of any misapprehension we may remark that, in making the assertion above, we have not the slightest idea of laying any claim to our having possessed a knowledge of the interesting fact discovered by Mr. Petschler, and which, the more we consider it, the more highly are we disposed to estimate it; but the course of operations pursued, when analysed, really amounts to the difference of washing the albumen before drying it, in the one case, and after drying it in the other. The chloride of sodium or ammonium may be substituted for the citrate or phosphate of soda with perfect indifference, as any one who has operated with the Fothergill process upon scientific principles knows as a matter of course; but we have preferred the salts mentioned on account of their producing greater intensity in the negative. In the plates, as prepared by Messrs. Petschler and Mann, we apprehend that the chloride might be replaced by the other salts, though possibly not so advantageously.

The facility of keeping plates in an insensitive condition, that can be rendered active by simple washing, is, to say the least, a very great convenience. On considering the *rationale* of the experiment it appears to us to stand thus:—All free nitrate of silver is converted into a chloride by *excess* of chloride of sodium or its analogue, and it is impossible to reduce the chloride of silver in presence of the free alkaline chloride, because as reduced it would be immediately reconverted into chloride of silver by decomposition of the surplus haloid salt; but by washing the plate the free chloride of sodium, which is soluble in water, being removed, the actinic action, if sufficiently prolonged, will reduce the chloride of silver just as in the ordinary printing process. The chloride of silver, however, being supported by a layer of iodide of silver, is much more readily acted on than when alone, as the iodide evidently possesses catalytic action, and conveys to the chloride the impulse received by it from the light. It is by no means improbable that an adaptation of this principle to the preparation of albumenised paper may solve the problem of satisfactory paper negatives.

That chloride of silver, even unaccompanied by free nitrate of the same base, would darken under actinic influence by partial reduction of the metal is a matter known to most photographers; but it is generally supposed that iodide of silver, under similar conditions, is quite insensitive to light. This is, however, an opinion that we have frequently combated as by no means *proved;* and we have, moreover, in the Daguerreotype plate an instance in which the direct contrary is established.

It is asserted that calotype paper that has been prepared with an excess of an alkaline iodide, which has been removed by copious washing, is not only insensitive to light, but actually improved by exposure to sunshine. But here again we take exception to the first postulate, and do not admit that the second is in any respect dependent thereon. Granted that the paper may be improved by exposure to light, does not that prove it *is sensitive* to its action? But we believe even more than this, viz., that the actinic impression is *removed* by the subsequent moistening of the paper in sensitising it. The point to which we were about to direct attention, however, is the very interesting one mentioned, that plates prepared with albumen and a chloride are more easily developed when *not* dipped into a second silver bath before exposure, while those prepared with albumen holding an iodide in solution act in a manner directly the reverse. This is another argument in favour of simplicity.

We feel very sure that our numerous readers will accord to the gentlemen who have brought forward the extremely valuable observations and experiments we have had the pleasure of laying before them their warmest thanks.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 11.

At the present time, when so much difference of opinion prevails as to the true theory of the dry collodion processes, any reasonable explanation which may be offered will be received with attention. Some time since, Mr. Burnett, of Edinburgh, gave expression to certain new views; and, almost simultaneously, Mr. Michael Hannaford propounded the same. These were, if we mistake not, in substance as follows:—In the wet collodion process free nitrate of silver imparts an increased sensitiveness to a film of iodide of silver. In a dry process this free nitrate must be removed, and its place supplied by a salt of silver either sparingly soluble or insoluble in water, such for instance as acetate, tartrate, citrate, oxalate, or chloride of silver. The theory, thus briefly expressed, is simple, and it had occurred to us as a probable one some time previous to the publication of the papers of Mr. Burnett and of Mr. Hannaford. The results of our experiments, however, were unfavourable, and did not uphold the theory to the extent anticipated. It certainly appeared that other salts of silver replacing the free nitrate were not without effect in a dry process; but at the same time we could not venture to deduce therefrom any conclusions admitting of general application.

Our first experiment consisted in an attempt to dissolve *a citrate* in collodion already containing a mixed iodide and bromide. There is a little difficulty in effecting this, since the citrates as a class are very sparingly soluble in alcohol and ether. We succeeded, however, to a sufficient extent, by neutralising citric acid with ammonia;

and having thus prepared a suitable collodion, we were in hopes that it would yield a dry sensitive film by simply washing with water after removal from the bath. This expectation, however, was not fulfilled; for the negative so obtained was feeble, and clouded over on the transparent parts. Conjecturing this to have been due to a too complete shrinking on drying, we next washed a film from the same collodion, with distilled water, and flooded it with solution of oxymel; but the negatives remained very weak and blue. If the citrate exerted any effect, it was clearly one which was not sufficiently marked to be distinguished with certainty.

Having abandoned the idea of adding the organic salt to the collodion, we next tried the effect of washing the surface of an excited bromo-iodised film with a solution of the organic salt, a portion of free nitrate of silver having been left upon the iodide, with which the organic salt might combine. The first salt chosen was the bimalate of ammonia, which we happened to have by us in a crystallised state, and which we were inclined to select from an idea that an acid malate might possibly be the active constituent in the syrup of wild raspberries, recently proposed as a preservative. Malate of silver appears, as regards its solubility in water, to occupy an intermediate position between the acetate of silver and the tartrate of silver: it dissolves in boiling water, but separates in little crystals on cooling. The first success with the acid malate was cheering, for the plates developed extremely quickly, and exhibited a fine red colour by transmitted light. It should be mentioned, however, that in no instance was the organic salt employed alone: cane sugar was always added in the proportion of twenty grains to the ounce, to keep the film open and prevent it from becoming hard and skinny on drying. A repetition of the experiments with the malate was less encouraging. It appeared that a part of the previous success had been due to the condition of the collodion: this had been bromo-iodised for more than six months, and had arrived precisely at the proper state, being sufficiently pappy, and yet not rotten; whilst the tendency to active development was so strong on the dried plate, that a simple solution of cane sugar flooded over the washed film gave all that was needed. Nevertheless, the acid malate had not been without effect even in this experiment, for plates prepared with sugar only were not solarised as much as those containing the organic salt in addition to the sugar. It remained, therefore, to repeat the experiments with the same bromo-iodised collodion newly mixed, and on doing so the true action of the malate became apparent: it gave vigour and redness when combined with nitrate of silver, but the plates were extremely uncertain, fogging when the proportion of nitrate was too much increased, and soon losing their characteristic properties. With the old collodion the tendency to fogging had not been seen, but this was evidently because old collodion preserves the clearness of the transparent parts better than new. The fogging also was not that description of clouding which takes place when the power of development is too much lowered, and which a little gallic acid left upon the film would remedy, but rather an incipient reduction of silver, such as one sometimes sees in the honey process, and which indicates that the chemical actions are running riot, and that a free acid must be used to control them.

Dismissing the malate, we proceeded with the tartrate, citrate, and oxalate; and, having satisfied ourselves that a little free acid was useful in preventing fogging,* we invariably worked with a bi-salt, and neutralised only a portion of the base. Citrate and oxalate are often classed together, but photographically they are very different. If both be employed in conjunction with chloride of silver, in a printing process, it will be found that the citrate alters the tone of the print to a red, whilst the oxalate has comparatively little effect upon the colour. Again, if citrate be added to an ordinary negative bath, it immediately robs it of its iodide, and carries the iodide down in insoluble combination; but it is very difficult to effect the same removal of iodide with an oxalate, and enough oxalate may be added to throw down more than half the silver in the bath, without precipitating the whole of the iodide. At first, indeed, we thought that there existed no affinity whatever between oxalate of silver and iodide of silver; but, on examining more carefully, it was found that a part of the iodide was carried down, although a part still remained in solution. We mention these facts to show that tartrate, citrate, and oxalate cannot be classed together as photographic agents, although the two former produce effects which are closely analagous. Whether it be that the tartrate and citrate act strongly in photography, because they have a certain affinity for oxygen, and that the oxalate acts less decidedly because it is an ultimate product of oxidation, we do not now stop to inquire: it will be sufficient to indicate the facts for the guidance of those who may follow us in this investigation.

The colour of the negatives was not precisely the same with the citrate as with the malate, and in the case of the oxalate it was different from either. The oxalate indeed proved useless, from its throwing down a visible deposit of oxalate of silver upon the film, and producing numerous transparent pin-holes; the tartrate did the same, but in a less degree.

Here we paused to consider how far it would be worth while to continue the experiments, since it appeared doubtful whether we were upon the right track. The organic salts of silver had evidently modified the colour and density of the negatives; but equally good pictures, perhaps better, were obtained by washing the collodion rather abundantly with water, and coating it with a simple organic substance, like gum arabic. In this case no salt of silver was present, except iodide and bromide;* whilst even the bromide could be dispensed with, and a picture obtained. The gum, however, or some analogous substance, appeared very useful, so that this seemed the proper direction for further experimenting.

Albumen has a remarkable action in dry processes, as all are aware, and albumen precipitates an insoluble compound with nitrate of silver. It does not, however, appear that other bodies, which also precipitate nitrate of silver, can be substituted for the albumen, and that citrate, oxalate, or chloride will succeed equally well. Albumen, therefore, must possess some additional property which renders it useful in dry processes, and whatever this property be, it seems to be possessed also by gelatine, gum, and to some extent also by cellulose.

As regards the composition of the sensitive iodide which receives the latent picture in the dry processes, we lay stress upon the fact that some varieties of pyroxyline can be shown to possess the property of withdrawing small quantities of nitrate of silver from the bath, and forming therewith a combination which resists for a time the decomposing action of a soluble chloride; therefore the film from a bromo-iodised collodion, which has been kept for six months in the iodised state is not to be viewed as simple iodide or bromide of silver, but rather as containing traces of organic compounds of silver associated with the bromide. If the pores of such a collodion are afterwards filled up with gum or gelatine, the conditions of permeability insisted on by Dr. Norris are fulfilled, and the development is thereby facilitated.

* It has already been mentioned that the plates in these experiments were prepared as if for the Fothergill process, each stereoscopic film being washed with half-an-ounce of water, before putting on the organic salt; free nitrate of silver was thus left upon the film.

* In making this observation we refer to salts of silver purposely added: on previous occasions we have expressed our belief that a minute portion of nitrate of silver is retained in organic combination with the pyroxyline, and that neither water alone or water containing salt will immediately decompose this compound.

THE PRACTICAL DETAILS OF PHOTO-ZINCOGRAPHY,

AS APPLIED AT THE ORDNANCE SURVEY OFFICE, SOUTHAMPTON,

For the Production and Multiplication of Facsimiles of Ancient Manuscripts Maps, and Line Engravings.

By Colonel Sir HENRY JAMES, R.E.,

Director of the Ordnance Survey.

THE art of copying ancient manuscripts or any outline engravings by means of photo-zincography is likely to prove of such great importance for the production of authentic copies of rare and valuable documents now locked up and inaccessible to the public, that I have thought it advisable, with the assistance of Captain A. de C. Scott, R.E. (who has charge under me of that branch of the work of the ordnance survey which includes the reduction of the plans by photography), to give to the public the result of our experience up to the present time. I am led to adopt this course in the desire to see this art brought to the highest degree of perfection of which it is susceptible, in the shortest possible time, and under the conviction that when some of the many highly talented and ingenious photographers we have in this country take up this branch of their art, they will be able to suggest and introduce improvements which may not occur to us.

The singular advantage which this art possesses consists in the fact, that we can now produce authentic copies of any of the numerous rare manuscripts which are carefully preserved in different parts of the world, and print any number of copies of them that may be required at a cost which will not exceed one penny for a folio-sized sheet,† and this without ever touching the original docu-

† In the report of the committee, of which Sir R. Murchison was chairman, it is stated that the annual saving effected by my having introduced photography as a means of reducing the Ordnance plans from the larger to the smaller scales, amounted, in the year 1858, to £1,615. Since then we have so much reduced the cost of the photograph, that the saving which will be effected will amount to £35,000 on the cost of the survey.

ment, or, if required, without even being in the same room with it, provided we only have a hole in the wall to place the lens of the camera in.

By the term "Photo-Zincography" is meant, as the name implies, the art of producing a photographic *facsimile* of any subject, such as a manuscript, a map, or line engraving, and transferring the photograph to zinc, thereby obtaining the power of multiplying copies in the same manner as is done from a drawing on a lithographic stone, or on a zinc plate.

The first part of the process concerns the production of a negative photograph on glass of the document, of exactly the same size as the original. This is obtained by the ordinary wet collodion process, and too great care cannot be taken to obtain one as perfect as possible, as every defect will be transmitted through each step of the process till it affects the final result. As affecting success at this stage, the lens used should be as perfect as possible, and fully capable of projecting an image of the size required without sensible distortion. Lenses are used at the Ordnance Survey Office of various diameters, depending on the size of the document to be copied — the largest being eight inches in diameter, forty-one inches in principal focal length, and capable of producing negatives free from sensible distortion sixteen inches square, a stop one inch in diameter being placed eight inches in front of it.

The distance from the lens to the ground-glass of the camera when adjusted so as to copy a subject to the same size, is seven feet three inches, and from the lens to the subject of course the same.

The readiest means of adjusting the camera and lens in their proper position relatively to the object and to each other when it is required to produce a negative the same size, is to ascertain by actual measurement with a proper scale a lineal dimension of the subject (as its width or length), and so to regulate the distance of the lens from it that, when the image is focussed on the ground-glass, it shall equal, in its corresponding dimension, that already read on the scale. This can easily be done by a system of repeated trial and correction of error. When the lens and camera are in adjustment, the glass plate is covered with the sensitive coating—exposed, developed, and fixed in the ordinary way; when fixed, it is immersed in a saturated solution of chloride of mercury (corrosive sublimate). When well whitened by the action of the salt, it is removed, washed with water, and then with a solution of hydrosulphate of ammonia, consisting of ten parts of water to one of hydrosulphate of ammonia of commerce.

In this manner the ground of the negative is rendered extremely dense, without affecting the clearness of the detail. When dried and varnished it is ready for use.

We now come to the preparation of the sensitive paper. The quality of the paper used is a point of much importance. Various samples have been tried, but that which has been found best suited for the purpose is a semi-transparent kind, with a smooth surface, known by the name of engravers' tracing paper.

A solution of gum arabic is prepared by dissolving three parts by weight of gum arabic in four parts of distilled water.

Boiling water is then saturated with bichromate of potassa, and one part of the solution of gum arabic is mixed with two parts of the solution of bichromate of potassa, both being kept at a temperature of about 200°.

The paper is evenly coated with the hot mixture with a flat camel-hair brush, and dried; it is then exposed under the negative in the usual way. The time required for printing may be said to vary from ten minutes in diffused light to two minutes in the sunlight, though there are days on which an exposure of twenty minutes would not impress a sufficiently marked image; but at such times it is not advisable to print, if it can be avoided, as the results will hardly be good. The period of exposure is determined by the appearance of the print: when all the details appear distinct it should be removed.

The next step of the process is the coating of the whole surface of the print with an even and thin layer of a greasy ink, which is composed of the following ingredients:—

Middle linseed oil varnish	$4\frac{1}{2}$ oz.
Wax	4 ,,
Tallow	$\frac{1}{2}$,,
Venice turpentine	$\frac{1}{2}$,,
Gum mastic	$\frac{1}{4}$,,
Lamp black	$3\frac{1}{2}$,,

A portion of the above is dissolved in oil of turpentine, so as to make a solution of the consistency of thin cream, which is easily applied to the surface of the print with a brush.

It should here be observed that the extent to which the greasy ink is diluted is in great measure determined by the nature of the subject photographed: if it is of an open nature, such as a bold engraving or etching, the solution may be considerably thicker than when the subject is finer. Experience is the only guide in determining this point.

The turpentine is allowed to evaporate for half-an-hour, and the print is then floated back downwards on hot water for a few minutes, and then removed, and laid face upwards on a porcelain slab.

The surface is gently rubbed with a sponge dipped in warm gum-water, and the ink readily leaves the surface at those parts which have been unacted on by light, while it adheres tenaciously to the detail.

As soon as the lines are quite clear, the print is placed in a flat dish, and washed first with warm and finally with cold water. When dry it is ready for transferring to zinc or stone.

There are two methods of transferring to zinc, varying according to the quantity of ink in the photograph.

If a very small quantity has been applied, on account of the closeness of the subject, the print is transferred by the anastatic process.

For this purpose the surface of the zinc plate is polished with emery powder, and made as smooth as possible. The print is placed for about ten minutes between sheets of paper, which have been damped as uniformly as possible with a mixture of nitric acid and water, in the proportion of five parts of water to one of concentrated acid. A sheet of paper, damped with the acid, is laid on the zinc plate, and both are passed between the cylinders of a copperplate printing-press, and the acid being forced on to the zinc slightly etches the surface. The paper is then taken off, and the film of nitrate of zinc formed on the plate is carefully cleared off with a handful of blotting-paper. The print is next laid on it face downwards, and both are passed once through the press. The paper is then pulled off, and the transfer is gummed and brought up by going lightly over the surface with a sponge dipped in printing ink, softened with olive oil. As soon as all the detail appears strong, it is etched with a very weak solution of phosphoric acid in gum water, the strength of the acid solution being so regulated that a drop placed on a smooth zinc plate for three minutes slightly tints or dulls the polish. The transfer is then ready for printing in the usual way.

If a larger quantity of ink has been applied the mode of transferring is somewhat different.

The plate is prepared by rubbing the surface with fine sand and water, and a zinc muller, to give it a grained surface. The print is laid for ten minutes between sheets of paper, damped as uniformly as possible with water: it is then laid, face downwards, on the plate, covered with two or three sheets of paper, and passed once through an ordinary lithographic press. The sheets of paper being removed, it is damped at the back with gum water, till its adhesion to the plate is so lessened that it can easily be pulled off. After the transfer has been gummed, brought up, and etched, as in the anastatic process, the ink is cleared off with turpentine, and the design is rolled up with printing ink. Impressions can then be taken from it. The photographic print can be transferred to stone in the same manner as to grained zinc, the surface of the stone being prepared as for ordinary lithographic transfers.

Having described the methods of transfer, it is necessary to treat further of the considerations which determine the quantity of the ink used, and consequently the mode of transfer. The quantity of ink which it is necessary to apply to the photograph to make a successful transfer to grained zinc is greater than that which is necessary for stone, and the anastatic process requires the least of all.

The action of the warm water, in which the print is immersed, on the insoluble gum, is to cause it to swell, and the ink which overlies the lines formed of insoluble gum expands likewise. It is evident, therefore, that if the subject photographed is of a close nature, as a fine engraving, the amount of enlargement of the ink lines may be sufficient to bring them into contact while the print is in the water, and when once they have coalesced, they will not again separate when the gum resumes its natural size, on the drying of the print, and there will be a continuous shade of ink instead of lines. In such a case the quantity of ink applied should be as small as possible, and, to enable a light but even coating to be laid on, it must also be thin; and, as a consequence of the small quantity of ink used, the transfer must be effected on a smooth plate by the anastatic process, because to make a successful transfer to a grained plate, or to stone, a larger quantity of ink is necessary.

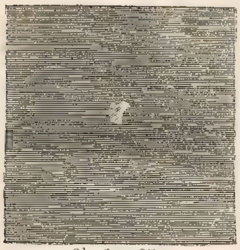
On the other hand, as impressions taken from a grained plate, or from stone, are, as a rule, better than those from a smooth plate, and as a larger number can moreover be struck off, if the subject photographed is so open that there does not appear to be any likelihood of the lines coalescing in the water, it is better to apply the ink in a greater quantity to the print, as a certain quantity is a *sine quâ non* for the employment of the latter mode of transfer.

[Those who may be interested in this important branch of photography, and are desirous of inspecting the results obtainable, will find a carefully-executed *facsimile* of an ancient manuscript in the Record Office, which has been copied and printed by photozincography at the Ordnance Survey Office, Southampton, in the last *Report of the Progress of the Ordnance Survey*, published by Messrs. Eyre and Spottiswoode, at Her Majesty's Stationery Office, London. Price 3s., by post 3s. 2d.—Ed.]

THE SOLAR ECLIPSE OF 18th JULY.

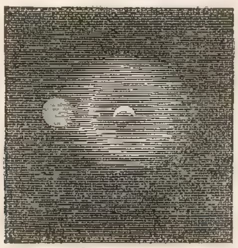
By Charles Heisch, F. C. S.,
Professor of Chemistry at the Middlesex Hospital.

I send herewith some photographs of the eclipse of July 18th, as seen at Greenwich, which may be interesting to your readers.



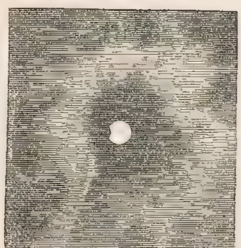
2h. 3m. 37s.

2h. 31m. 37s.



2h. 48m. 7s.

3h. 7m. 37s.



3h. 47m. 57s.

I should be very glad if any one can offer an explanation of the curious moonlike reflection visible in three of them, most vivid at the moment of greatest eclipse. I at first thought it might be due to some reflection in the camera, but became convinced that it was not so on observing the manner in which the image shifted its position with regard to the sun as the moon's shadow passed over it. I have since found that the appearance in question was *seen* by several independent observers, who describe it as "like a faint moon," somewhat to the left of the eclipsed sun as you look at it.

So many objections present themselves to every explanation which I have yet thought of that I prefer attempting none, hoping to get a better from some one else.

I should mention that the camera was mounted on the stand of an astronomical telescope; the image of the sun brought to the centre of the ground glass. The exposure was, I should think, about one-eighth of a second, but I cannot say very exactly.

Blackheath, August, 1860.

CELESTIAL AND INSTANTANEOUS PHOTOGRAPHY.

By Warren De la Rue, Esq., F.R.S., F.R.A.S., &c.

(Continued from page 239.)

Collodion.—The condition of the collodion is also an all-important point, and it appears to be very capricious in its properties. It is preferable not to make the collodion oneself, but to use that prepared by makers of repute; I usually employ Thomas's or Hardwich's collodion, both of which I have found to be very uniform in quality.

It is desirable to sensitise frequently new batches of collodion, and to determine by experiment from time to time the gradual development and decline of their sensitiveness.

Collodion should not be sensitised until after it has stood for, at least, a week after it has been purchased, and it must then be carefully poured into the mixing vessel without disturbing the sediment which always is present. It must be agitated occasionally for some hours after mixing with the sensitiser, before it is set aside to rest and deposit the new sediment which forms. After standing for a week, it should be carefully decanted for use, to the extent of three-fourths, into a perfectly clean glass vessel.

The glass mixing vessels should invariably, previous to use a second time, be washed out, first with a mixture of equal parts of ether and alcohol, and then with water and pieces of blotting-paper, well shaken up, so as to reduce the paper to pulp; and finally, rinsed out with distilled water, and suspended in a warm place, mouth downwards, to drain and dry thoroughly.

Iodide of cadmium appears, on the whole, to be the best sensitiser for collodion to be used in celestial photography: collodion prepared with this salt is not very active when first mixed; hence it differs from collodion prepared with iodide of potassium and iodide of ammonium in this respect, but it gradually acquires a degree of sensitiveness unsurpassed, if equalled, by collodion rendered active with the latter salts, used either alone or mixed with other salts. Collodion mixed with iodide of potassium acquires, it is true, great sensitiveness soon after it is prepared, but in a few days it loses in this respect, is moreover continually changing, and is seldom available in celestial photography after standing a month or six weeks; whereas cadmium collodion will retain its qualities for several months. As fresh mixed collodion is certain to produce both white and dark specks in the photograph, as large or larger than the details visible in the picture with a magnifier, it will be seen that a collodion which can be kept for a long time to deposit, without losing in sensitiveness, must be the most valuable; moreover, in collodion mixed with the alkaline iodides there is always an evolution of free iodine which soon impairs the sensitiveness of the nitrate of silver bath by rendering it acid; and for these reasons I generally give the preference to cadmium collodion.

Sometimes collodion exhibits a reticulated structure after the photograph has dried, which materially militates against the beauty of the picture, and prevents its being highly magnified; it occasionally happens that this defect cannot be cured, in which case the collodion should be rejected. I have generally found, however, that this "craping" may be obviated if the collodion be diluted, more or less, with a mixture of two parts of ether and one part of alcohol when it is being sensitised, care being taken to add as much of the solution of iodide in relation to the diluting liquids as would have to be added to an equal volume of collodion.

After using collodion for several evenings, it is well to allow it to stand for some days, and to decant about three-fourths into a fresh vessel.

Before pouring the collodion on to the glass plate, the usual precaution of cleaning away with the fingers any dried collodion from the lip of the containing vessel must be attended to; moreover, each time, just in the act of pouring, a few drops should be allowed to fall to waste on the floor; by attention to these remarks much vexation will be avoided.

Exposure of the Plate in the Telescope.—On taking the plate from the nitrate of silver bath it is desirable to drain it well before it is put into the slide, first on the edge of the bath, then on white blotting-paper, shifting its position two or three times, but always keeping the same point downwards. It must be carried to the telescope as quickly as possible, and the picture developed immediately after it has been removed from it.

The sensitised plate rests on angles of pure silver, let into the square plate-holder, or in the circular plate-holder within a ring of pure silver, the face resting on three prominent places. I have found that contact with wood is liable to produce stains which occasionally extend across the plate during the development. The

circular plate-holder is entirely of metal, and I would recommend metal holders in preference to those of wood for celestial photography, because they are not liable to warp and become set from damp when left in the observatory. The plate-holder should be wiped with a clean cloth after each operation, and the hands also washed each time before a fresh plate is taken, on which it is intended to pour collodion.

In order to subject the sensitised plate to the action of light when the telescope is used as a Newtonian, I remove a very light cover, previously placed over the mouth of the telescope, and replace it when I wish to discontinue the action; this cover is made of black merino, stretched on a whalebone hoop, and is provided with a handle of bamboo. In the direct method, I turn up or down, through an arc of 90°, a little hinged trap, interposed between the great mirror and the sensitive plate. This motion is given by means of a lever fixed on a light axis, supported by the arm which holds the small camera; the axis extending beyond the edge of the telescope tube, and carrying a milled head by which it is turned.

Regulation of the Time of Exposure.—A journeyman-clock, beating seconds distinctly, should be near the telescope, in order that the operator may be enabled to regulate the time of exposure, which requires great nicety with such sensitive chemicals as must be employed.

The time occupied in taking lunar pictures varies considerably; it depends on the sensitiveness of the chemicals, on the temperature, on the altitude of the moon and her phase. An almost imperceptible mist in the atmosphere will sometimes double the time of exposure, but, curiously enough, a bright fleecy cloud passing over the moon scarcely stops any of the actinic rays. I have recently produced an instantaneous picture of the full moon, and usually get strong pictures of the moon in that phase in from one to five seconds. The moon as a crescent, under like circumstances, would require about twenty to thirty seconds, in order to obtain a picture of all the parts visible towards the dark limb.

Development of the Picture.—Of all the developing mixtures tried I give the preference to the aceto-pyrogallic acid solution, which is generally used in the ordinary proportions: namely, pyrogallic acid, three grains; glacial acetic acid, one fluid drachm; distilled water, three fluid ounces; but, in cold weather, I sometimes reduce the quantity of acetic acid to one half, to render the solution more active. The developing fluid retains its properties for a week or more after mixing. It is desirable to pour out the requisite quantity of fluid in a small vessel, and to place it in readiness, before the plate is removed from the bath and put into the slide, so as to prevent any delay after the plate has been exposed in the telescope. This precaution obviates the staining which arises sometimes by partial drying of the film.

The addition of nitrate of silver to aid in bringing out the picture must be avoided; pictures thus intensified will not bear any magnifying power, and are comparatively worthless. Hence it will be seen how all-important it is to have the bath and collodion in their most sensitive condition. The negative should not be developed too strongly, as such pictures never copy so well as those moderately but distinctly brought out. Such small photographic pictures as those of Jupiter and Saturn present many obstacles to their development, on account of the difficulty of discerning them during the operation; for the focal image of Jupiter in my telescope, even when the planet is in opposition, is only about $\frac{1}{37}$th of an inch in diameter.

After the development of the picture to the desired point, the further development is arrested by pouring a quantity of water on the plate, and a vessel containing water should be at hand for this purpose.

Fixing the Picture.—By preference I use hyposulphite of soda for fixing; after fixing, the plate is washed under the tap of a cistern of water for a short time, and then examined with a lens. If worth retaining, the epoch of the picture, and other particulars are recorded at the back with a writing diamond. The plate is then washed again, front and back, in a stream of water, and placed face upwards on a tripod stand, duly levelled; rain-water* is poured on the collodion, and from time to time this is poured off, and fresh poured on, in the meantime other photographs are proceeded with. After half an hour or more, the plate is thoroughly washed in a stream of rain-water, and placed edgewise on blotting-paper against the wall, to drain and dry.

Varnishing.—The next morning the negatives are warmed before a fire, and varnished with Sœhnée's varnish,† which is the only description I have found to stand. I am careful to filter the varnish before using, otherwise specks might be transferred to the photograph. It is very desirable to varnish the plates as soon as they are dry, for, if left unvarnished for any length of time, they can never be varnished evenly.

(To be continued.)

* In preparing the bath and developing solutions, distilled water must be employed, but filtered rain-water answers very well for washing the photographs.

ON THE CHLORIDES OF GOLD AND THEIR EMPLOYMENT IN PHOTOGRAPHY.

By M. Fordos.

The gold baths employed in photography are prepared by adding to a solution of hyposulphite of soda either a solution of *sel d'or* (hyposulphite of soda and gold) or a solution of chloride of gold. But it is very wisely recommended not to make use of an acid chloride, but of a perfectly neutral chloride of gold. Now all the chlorides of gold are more or less acid; and the constant presence of acid in these products, even the best prepared, led me to think there might be some advantage in studying the preparation of this compound, and by this study I have arrived at results very beneficial to the art of photography.

The prescribed mode of preparing chloride of gold is very simple, but it does not furnish a pure neutral chloride of the formula

$$Au \cdot Cl_3$$

The following experiment will serve to explain the different stages of preparation, as well as the variable results to which they inevitably lead:—

When twenty-five parts of gold are dissolved in a mixture of twenty-five parts nitric acid and seventy-five parts of hydrochloric acid, and the solution evaporated at a gentle heat in a weighed capsule, the following facts may be observed:—the solution is orange yellow, and disengages abundant acid vapours, and the liquid is reduced to between fifty-one and fifty-two parts. At this moment the liquid begins to deepen in colour, and the disengagement of acid vapours appears to cease. If the capsule be then withdrawn from the fire, the liquid soon becomes a crystalline mass formed of long needles. In this manner we obtain a hydrated hydrochlorate of chloride of gold, and this is the purest commercial product. If, instead of withdrawing the capsule from the fire, it is continued thereon at a gentle heat, it slowly disengages invisible acid vapours, but at the same time a part of the perchloride is transformed into protochloride; and in endeavouring thus to free the chloride of gold from its excess of acid, we eventually obtain a product which contains protochloride in proportion as the heat has been continued. The chloride obtained in this way is of a ruby red, more or less deep. It is not completely soluble in water, and when treated by that liquid we see the protochloride of gold separate under the form of a yellowish white powder; but this protochloride soon transforms itself into perchloride by parting with some of its gold.

This experiment shows that in the preparation of chloride of gold we are placed between two dangers: we obtain either an acid chloride or a chloride containing protochloride. Photographers should abandon the use of chlorides of gold thus obtained, because they are of uncertain composition, and, besides, they are always acid. We may add, that they are so hygroscopic that this property renders them very difficult to manipulate.

We believe that photographers will find many advantages in employing the double chlorides of gold and potassium, and of gold and sodium. These double chlorides contain as much gold as the commercial chlorides of gold, and may be employed in the same doses. They are neutral, and have an invariable constitution. They possess great stability, and do not attract moisture from the atmosphere. Photographers might buy these chlorides by the half ounce or ounce: it will always be easy to weigh the quantities required for each operation, without the fear of the salt liquifying and rendering the weighing difficult.

THE ACTION OF LIGHT ON THE COLOURING MATTER FROM THE "MUREX."

The photogenic properties of the mollusk, from which the ancients are supposed to have obtained their famed Tyrean purple-dye, have some time since, been investigated by M. Lacaze Duthiers, who submitted a very elaborate memoir on this curious and interesting subject to the *Academie des Sciences.* In the first place it is necessary to premise that the term *purple* has, at various periods in the world's history, been applied to various colours more or less red. Strictly speaking, it should be restricted to the pure

secondary colour of the prismatic spectrum composed of pure red and pure blue, in which the blue is in greater proportion than it is in violet, which may be considered as composed of equal quantities of pure prismatic blue and red.

M. Duthiers's researches have been directed to several species of *murex* and *purpura*. Anatomical investigation shows that the purple colouring matter is primarily a colourless substance produced by a very limited portion of the *mantle* of the animal, occupying the small space between the branchiæ and the rectum. It forms neither a pouch, a sack, nor a reservoir, as frequently asserted, nor even a purple vein, but is merely spread over the surface of the mantle. Its tissue is composed of large elongated cells placed beside each other, perpendicularly to the surface of the pallial arch, in the direction of its greatest diameter. When they have arrived at maturity these cells fall into the pallial cavity, swell by endosmose, break, and mingle their contents with other mucosities. This fall of the elements, isolated and independent, constitutes the secretion of the purple matter, at first colourless, white, or slightly yellow, in the living animal, but which, submitted to the sun's rays in conjunction with moisture, become of a fine violet colour.

The action of light develops the three primary colours in the following order:—Yellow, blue, red. Between these we find green resulting from the mixture of yellow with blue, and violet resulting from mixture of blue with red. In making the experiment slowly—that is, in diffused light—this succession of colours may be distinctly observed. But while the yellow disappears when the action of light is prolonged, the blue always remains in notable quantity—so that the red is never found (naturally) alone, and the hue of the purple is always more or less violet.

These properties are placed beyond the reach of doubt by the possibility of producing photographs upon silk or woollen tissues; and the results obtained without exhibiting the perfection of ordinary photographs exhibit, nevertheless, good detail and vigorous tones.

In a photographic image thus obtained we recognise some of the colours mentioned above. The greenish yellow corresponds to white, and the violet, more or less deep, to the blacks of ordinary photographs.

Different species of the *murex* yield different hues. From the *Murex trunculus* a blue is obtained, almost devoid of red or of violet.

The esteem in which this pigment was held was doubtless partly due to the source from whence it was derived. Developed by the agency of light, light would not cause it to fade, as it does so many other pigments. It would remain always brilliant, even under the luminous dazzling skies of Italy and the East.

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING THE PHOTOGRAPHIC IMAGE.

Report of the Committee, consisting of Messrs. Maskelyne, Hadow, Hardwich, *and* Llewelyn.

(Continued from page 238.)

But if the tissue of the paper is not to be altogether excluded from the list of possible co-operative agents present in these processes, there are other substances of which the influence can be demonstrated in a manner quite satisfactory to the photographist. Gelatine as size was long employed without his being conscious of its importance; and he now uses albumen as a photographic glaze, and sometimes other substances, such as grape sugar, Iceland moss, caseine, &c., on account of the fine tones and permanence in the fixing bath which they impart to his pictures. Gelatine and albumen both combine with nitrate of silver; and the character of the combination is one which chemistry has yet to explain with completeness. These compounds differ from each other in many important respects: we shall select that with gelatine for illustration. The characters of the compound of gelatine and nitrate of silver are exhibited by the following statements:—

If a sheet of transparent gelatine be floated upon a solution of nitrate of silver, the solution loses a considerable amount of the dissolved salt. When the proportion of the gelatine to the bulk and strength of the solution is sufficient, free nitrate of silver is scarcely to be detected in the bath, and what silver is found there is probably in the form of a gelatine compound, which is not entirely insoluble. The gelatine mass, though but slightly soluble in cold, is so to a considerable amount in hot water, and retains at once the neutrality and the taste of the nitrate. The solution gives the following reactions:—

Caustic potash throws down a bulky olive-brown precipitate, which clots into a tough extensile mass. This dissolves by boiling with excess of the precipitant, yielding a very dark and, when diluted, a clear yellowish-brown solution.

Strong ammonia produces no precipitate, but on boiling forms a pale orange-yellow solution, on which the light produces little or no change.

Chloride of ammonium, introduced cautiously, produces no precipitate, but in excess renders the solution turbid. The clear liquid is not rendered turbid by boiling; but a few drops of nitric acid, if the temperature be raised to the boiling point, suffice to render it milky from separation of the chloride of silver, which may be redissolved by ammonia, or darkened by the light.

Iodide of potassium, unless carefully introduced, throws down a turbidity of a yellow tint in it. But if this be removed by filtration, it will be found that the addition of the most dilute nitric acid and boiling throws down a fresh amount of iodide of silver.

Cold nitric acid produces no change in the gelatino-nitrate (?) of silver, even when formed from the ordinary commercial gelatine; but boiling throws down sometimes a small quantity of chloride, originating in the impurity of that body.

Chlorhydric acid, in minute quantity, produces also no precipitate until boiled, when the chloride of silver separates from the compound.

The gelatinous mass, formed by the action of the nitrate of silver solution upon the gelatine, becomes, on exposure to the sunlight, of a red colour. The change is a rapid one, and is accompanied by a shrinking of the mass to its original character of a thin sheet as it dries. The colour attained by prolonged solar influence is by transmitted light a deep ruby, and a "bronzed" green by reflected light. Sheets of the gelatino-nitrate of silver thus solarised no longer swell up or dissolve in boiling water, but only after long boiling become disintegrated in filmy fragments. Potash gives, on boiling, a clear solution, which even when dilute is brownish-red, and appears opaque when concentrated. Ammonia added to this liquid diminishes its opacity, and gives it an orange hue.

In inquiring what the character of the change effected in these bodies is, we would direct attention to a process analogous to that by which the citrate of silver was examined. If hydrogen be freely passed over the albuminate of silver in a water bath, this becomes converted into a red body resembling in all essential particulars the red substance into which the light converts the same albuminate. In each case the reaction with the different tests is the same. That, in fact, a suboxide is in each case formed, and that this suboxide is in combination with the albuminous or gelatinous substance, seems the natural conclusion from what has preceded, no less than from the reactions of the bodies themselves.

The silver cannot be there in the metallic form; else, why should potash dissolve it? and why should ammonia convert it into a paler body? Moreover, metallic mercury does not amalgamate with it. One reaction, indeed, might be urged as militating against this view. The hyposulphite of soda has but little action on the red compound, whereas it dissevers the constituent elements of suboxide of silver as dissolved oxide of silver and residuary metal. But we have shown that silver is not entirely precipitated from its gelatinous nor from its albuminous compound by such tests as chlorides or iodides, and one will hardly therefore see with wonder that the albuminate or gelatinate of the suboxide resists the action of the alkaline hyposulphite. Nor would it be out of place here to hint, as our colleague, Mr. Hardwich, has done, at the high probability of the suboxide of silver associating itself with organic substances, such as cellulose, albumen, gelatine, &c., in a manner analogous to that in which other metallic salts, in which the metallic element is not entirely saturated by metalloid elements, act the part of conjugate bodies, annexing themselves to the organic substances alluded to, and to colouring matters of various kinds. The action of these mordants belongs still to an obscure chapter of chemistry, but it is highly probable that the compounds under consideration are closely allied to them.

Finally, we have to bear in mind that the fixing agent modifies the image formed by the light in the materials we have been considering.

The alkaline hyposulphite, like ammonia, acts on the subchloride or the suboxide of silver, splitting the one into metallic silver and chloride which becomes dissolved, and the other into oxide and metal.

Obviously the conversion of an image formed of either of the intensely colorific subcompounds of silver into a pale metallic deposit containing only half the amount of metal, and possessing

none of the remarkable colorific energy of the suboxide or subchloride, is a conversion that can only be expected to exhibit a great loss of tone. Practically the singular immunity from this dissevering action which the organic matter, combined with or conjugated to the subcompound of silver, extends to that subcompound, comes in to help the photographist from losing the beautiful result which the light itself produces. And what little he still must lose he can almost restore again by the remarkable toning methods which he has recourse to.

The rationale of these toning methods is to be sought in the chemistry of each different process. The deposit of gold from a solution of that metal is in its broad features a simple reaction—a deposit of a more electro-positive metal in substitution of one less so; but the precise details of each method of using a gold toning-bath doubtless involve more refined chemical explanations. Without attempting to go into these, we would invite attention, however, to the sulphuretting baths by which this toning is sometimes conferred on the pictures. Sulphide of ammonium converts the fixed image on paper into, first, an intensely black compound, and subsequently, by its continued action, into a dull yellowish, scarcely visible stain. The latter, there can be little doubt, is sulphide of silver. It seems highly probable that the intermediate step in the process is the production of a subsulphide, and that it is at that stage that the progress of sulphurising is arrested in a successfully-toned picture. This explanation would be quite in harmony with the conditions under which the toning is performed.

The results, then, at which we conceive that photographic chemistry may be said to have now arrived, in respect to the direct processes involving the use of silver salts, may be thus stated.

The materials employed perform various functions:—

1st. One of these is that of supporting the picture, as a mechanical material or basis for holding the chemical bodies. Of the substances so employed the tissue of paper is one. Pyroxyline (the product of a substitution effected in the elements of the cellulose) is spread on glass to afford another. The latter appears to be inert. The former, on the other hand, seems to aid in the reduction, and possibly, in some cases, to remain in union with the reduced result.

2ndly. The silver salts employed, whereof the chloride—for which may be substituted other salts, as the tribasic phosphate, the tartrate, the citrate, and many others, though each with a specific effect—appears to act by imparting *sensitiveness*. The nitrate, on the other hand, is present in excess to keep up a constant succession of sensitive material, and so to give *vigour* and *intensity* to the image.

3rdly. Gelatine as a size, or albumen as a glaze, and various other substitutes for these (though but little linked together by any chemical analogy amongst themselves) co-operate by conferring *rich tints* and deep tones, while they at once impart to the image formed on them an immunity from the destroying action of the fixing process, and form a mechanical surface more or less impenetrable, which prevents the other sensitive compounds from sinking into the paper.

Each of these substances can, provided nitrate of silver be present, be employed to produce an image. Thus, the chloride rapidly produces a faint picture; the "gelatino-nitrate" slowly yields an intense one; together they produce the required result. Whether that result is a cumulative one, the sum of the separate results, or a conjoint one produced by a combination of the chloride with the gelatine compound, it were difficult to say.

The image is, however, a mixed one, for treatment of it with dilute nitric acid leaves the slaty violet subchloride of silver. It seems, therefore, to be a mixture of subchloride with a gelatinous, and perhaps, also, a cellulose-compound of suboxide of silver.

The next great division of our subject which we have to enter upon is that of photographs produced by development.

Fortunately, in dealing with the images thus formed, we are able to dissever the results from the magic influence that calls them into being. We need only show that certain conditions are necessary for the impress of the invisible image; we are not called on to explain the character of the impress itself. Without attempting to explain what goes on in the camera obscura, we may determine the conditions for a favourable action in it, and interpret the results of that action after development; though even here, from the great delicacy of the processes employed, the task is a most difficult one.

With regard then, first, to the preparatory portion of these processes involving the production of the sensitive surface. This consists, in the processes on glass, in a supporting film, and generally in iodide of silver formed under conditions in which nitrate of silver was in excess. There are also generally present other ingredients, such as certain forms of organic matter, and in some cases bromide or even chloride of silver.

That it is not a matter of indifference whether the supporting basis, or film, consist of pyroxyline, or albumen, or gelatine, or of these severally combined with other bodies or with each other, one might readily suppose from what has been already said under the head of direct processes; and it will be no difficult matter to show more than a probability that this is not due to a "molecular," but to a "chemical" distinction in the action of these bodies.

(To be continued.)

OBSERVATIONS ON THE TINCTORIAL PROPERTIES OF ALBUMEN.

By M. Guignet.

These observations have been conducted upon a cotton fabric impressed with albumen, and exposed to steam, so as to coagulate the albumen.

In the albumenised parts, the cotton readily takes certain dyes which wool and silk do not take: it becomes tinted yellow by picric acid, and red by fuchsine, &c.

This property has been known and applied a long time in factories. I have observed certain facts which reveal new tinctorial properties in albumen, which the industrial arts will, doubtless, also turn to account.

A fabric printed with albumen is quickly moistened in pure water, except the albumenised parts, which are penetrated by the water very slowly.

If a liquid, insoluble in water, is added to the water, and stirred briskly, this liquid will go only to the albumenised parts and tinge them, if it contains a colouring matter of a suitable nature. For example:—Water and a fat oil holding alkanet in solution: water and crude aniline (which tinges albumen brown), &c. Aqueous solution of iodine tinges albumen yellow. In contact with water holding starch in suspension, this yellow tint becomes green, then blue, and disappears entirely. The iodine leaves the albumen to go to the starch, and the blue colouring becomes imperceptible in the mass.

Neutral chromate of potassa gives no tinge to albumen; but the bichromate, or a diluted solution of chromic acid, tinges it yellow.

Albumen also assumes a vivid citron yellow colour in a solution of acetate of lead; red in a strong solution of nitrate of silver; black in a bath of logwood.

Permanganate of potassa tinges albumen brown, without tinging the non-albumenised parts.

Albumen is tinged a pale yellow brown in a boiling solution of a salt of the peroxide of iron. Prepared in this manner, it assumes a *blue* colour with ferrid cyanide of potassium—*violet* with decoction of madder—*black* with logwood, &c.

In a solution of sulphate of copper, albumen acquires no tinge; but it is coloured blue in a solution of ammoniacal sulphate of copper. By the action of alkalis, this blue tint becomes a very vivid violet lilac. With ferrid cyanide of potassium the marron-red tint of ferrid cyanide of copper is obtained. Ammoniacal solution of cobalt also tinges albumen.

The salts of gold, platinum, and palladium, also tinge albumen yellow without affecting the non-albumenised tissue. Albumen tinged with chloride of gold becomes of a deep violet, almost black with protochloride of tin or protosulphate of iron. Albumen tinged with chloride of platinum is coloured of a vivid yellow brown with protochloride of tin.

Finally, as might easily have been foreseen, albumen printed upon cotton also fixes bichloride of mercury, and assumes the scarlet hue of bin-iodide of mercury when treated with a very dilute solution of iodide of potassium.

ON THE DISCOLOURATION OF SILVER BATHS BY ALBUMENISED PAPER.

By J. B. Cassan.

In seeking to avoid the annoyance of losing silver baths which become decomposed in sensitising positive albumenised paper, I believe I have found a method at once simple, expeditious, and efficacious.

Nitrate of silver renders albumen insoluble; still, in coagulating, this albumen leaves some organic matter dissolved in the bath, which gradually alters it, and soon renders it unfit for use.

Whenever an albumenised surface is put into contact with a silver bath, the latter becomes yellow, and consequently almost lost, if the albumen be not previously coagulated.

To lessen the deterioration of the positive baths, some operators place the albumenised papers under a protecting sheet of paper, and coagulate the albumen by passing a hot iron over it.

Others apply the back of the sheets of paper to boiling water.

This last method, although excellent in theory, cannot be employed; because it takes a long time to prepare a few papers, and it is difficult to prevent the boiling water from moistening the albumened surface, and the paper must be dried again before it can be sensitised.

The same objections apply to the employment of a hot iron: for if it be too hot, the paper becomes scorched; and if it is not warm enough, the organic matter of the albumen will become soluble in the nitrate bath. And it is difficult to supply with the iron an equal amount of heat over the entire surface of the paper.

The method I propose consists in simply coagulating the albumen by putting it into a tin box, and placing the box, securely covered, in a vessel of boiling water, and kept there a sufficient length of time. There is no inconvenience to be feared from too long an immersion.

If the box be sufficiently large, as much as one or two quires of paper may be prepared at once, as the heat soon penetrates the entire mass of the paper.

ON FIXING POSITIVE PROOFS.

By MM. Davanne and Girard.

(Continued from page 240.)

Thus it is that, on placing printed proofs in the hyposulphite bath, many reactions may be successively produced, according to the amount of silver that is prescribed to the hyposulphite. Besides, it is proved by experience that these reactions will be exactly the same whether the nitrate or chloride is under consideration, only they will be more rapid with the first than the second. At first, a part of the hyposulphite acting upon the silver salt forms hyposulphite of silver $Ag\,O\,S^2\,O^2$; but the latter, encountering an excess of the soda salt, forms immediately the double salt $Ag\,O\,S^2\,O^2\,(Na\,O\,S^2\,O^2)\,2$, which, being very soluble in water, and particularly in hyposulphite, is immediately dissolved. Consider, for instance, the case of a proof previously washed in water, and nothing but chloride of silver retained. The following formula will explain the reaction that occurs:—

$$(\beta) \qquad 3\,S^2\,O^2\,Na\,O,\,5\,HO + Ag\,Cl$$
$$= 2\,(S^2\,O^2\,Na\,O)\,S^2\,O^2\,Ag\,O + Na\,Cl + 5\,HO.$$

This salt once formed, if some fresh proofs and, consequently, fresh quantities of chloride of silver are added to the solution previously obtained, the salt $Ag\,O\,S^2\,O^2,\,(Na\,O\,S^2\,O^2)\,2$, tends to form the compound $Ag\,O\,S^2\,O^2,\,Na\,O\,S^2\,O^2$ after the reaction—

$$(\gamma) \qquad 2\,(S^2\,O^2\,Na\,O)^2,\,S^2\,O^2\,Ag\,O + Ag\,Cl$$
$$= 3\,(S^2\,O^2\,Na\,O)\,(S^2\,O^2\,Ag\,O) + Na\,Cl.$$

But this compound $(S^2\,O^2\,Na\,O)\,(S^2\,O^2\,Ag\,O)$ is insoluble in water, and, therefore, tends to deposit itself in a crystalline state on the sides of the vessel in use, if the liquid is allowed to rest, or in a pulverulent state, in the texture of the paper, or in the liquid, if, as is the case in ordinary fixing, the liquid is frequently stirred.

From this time considerable danger is manifest. On one hand, in fact, as shown in defining the double salt, it is, in the mass of water, very easily decomposable into sulphide of silver and sulphuric acid, susceptible of engendering a deposit of sulphur; on the other hand, if we place this salt in the presence of a fresh quantity of the silver salt it will form free hyposulphite of silver.

$$(\delta) \qquad (S^2\,O^2\,Na\,O)\,(S^2\,O^2\,Ag\,O) + Ag\,Cl$$
$$= (S^2\,O^2\,Ag\,O)\,2 + Na\,Cl;$$

and, as we already know, this hyposulphite of silver immediately shows an inclination to decompose after the reaction—

$$S^2\,O^2\,Ag\,O + H\,O = Ag\,S + S\,O_3\,H\,O.$$

The preceding reactions are only clearly established when to the same quantity of hyposulphite indefinite quantities of chloride of silver are added, and there exists a limit of saturation in the solubility of the latter which it is important to determine. In short, the question may be stated in these terms:—

Whenever the fixing of hyposulphite of soda is made under such conditions that the hyposulphite of silver, or the second double salt $(S^2\,O^2\,Ag\,O)\,(S^2\,O^2\,Na\,O)$, exists for a short time in contact with the proof, without the power to dissolve in an excess of hyposulphite, it will be decomposed in the tissue of the sheet of paper, according to the reaction *(a)*, and in consequence of the formation of sulphuric acid, gives rise to the decomposition of one equivalent,

$$(\beta) \qquad S\,O^3 + S^2O^2\,Na\,O = S\,O^3,\,Na\,O + S\,O^2 + S.$$

The sulphur thus formed is deposited on the proof, side by side with the sulphide of silver, so that, not only one part of the silver covering the proof will be sulphurised on removal from the bath, but it will also imbibe a second quantity of silver, which, by degrees, sulphurising the unaltered silver, will attack the proof, and cause it to undergo a very considerable sulphurisation.

To seek out the conditions under which these accidents can be produced is that which must now occupy our attention.

Some are accidental; others are produced normally when the same bath is employed for fixing too great a number of proofs. We will examine each successively.

When a proof, on being taken from the printing frame, is plunged directly into the fixing bath, it should be immediately stirred, and this repeated every now and then. This precaution becomes of the greatest importance if the proof has not been washed in water, and thus retains nitrate. Reasoning indicates and experience proves that the *soluble* nitrate of silver acts upon the hyposulphite more rapidly than the *insoluble* chloride. Without this, a very great quantity of hyposulphite of silver would be formed in contact with the proof, and, not encountering a sufficient quantity of hyposulphite of soda to dissolve it, is precipitated, and afterwards decomposed: therefore we may come to this conclusion:—

If a large number of proofs are placed in the same bath almost in contact, without being separated by a sufficient space, so that, on agitating the dish, the hyposulphite of soda cannot flow between each sheet, the same accident presents itself in this instance as in the first, and the proof will very probably be spoilt.

An accident of the same kind, but confined to one spot, is produced if an air-bubble insinuates itself between the sheets whilst being fixed. Then the hyposulphite of soda, being raised by capillary attraction through the fibres of the paper corresponding to the size of the air-bubble, will form in the same place hyposulphite of silver, which, not being dissolved, is immediately decomposed on the part, and forms those yellow stains which photographers know too well.

We will now take into consideration the normal cause of the decomposition of the hyposulphite bath — that is to say, the saturation of this salt by silver compounds. From what has been previously stated, this limit of saturation is easily determined. Thus, from what has been shown in the preceding reactions, the danger is not to be apprehended but at the moment the insoluble and easily decomposable compound $(Ag\,O\,S^2\,O^2)\,(Na\,O\,S^2\,O^2)$ is on the point of being formed. But this moment is easy to define — it results from the two reactions (β) and (γ), which, combined, can be explained in the following manner:—

$$S^2\,O^2\,Na\,O,\,5\,H\,O + Ag\,Cl$$
$$= S^2\,O^2\,Ag\,O,\,S^2\,O^2\,Na\,O + Na\,Cl + 5\,H\,O.$$

If the preceding formula be calculated, we shall find that for this reaction to occur it will be necessary to introduce 100 hyposulphite of soda and 38 chloride of silver. It is, therefore, only when the hyposulphite employed shall have dissolved about one-third of its weight of chloride of silver, that the proof will incur the risk of being charged with sulphur.*

This is certainly a large proportion: photographers never attain it, for it corresponds to the fixing of fifteen whole sheets in thirty-five ounces of a solution of hyposulphite of ten per cent. Thus it would be difficult to understand the rapid alteration of the fixing bath if a new and very important cause did not intervene to hasten their decomposition. We have to speak of the action of light.

The Action of Light.—If we dissolve chloride of silver in a solution of hyposulphite of soda in very various proportions, from the one hundredth of its weight until the point of saturation is greatly exceeded, that is to say, the third of its weight [in the latter case, it will be found much of the crystallised salt $(Ag\,O\,S^2\,O^2)\,(Na\,O\,S_2\,O^2)$ will be precipitated]; and if we divide each of the solutions into two parts, and expose the half of each to the action of light, whilst the other half is kept in total darkness, we find that at the expiration of a certain period, varying from some hours to many days, all the solutions exposed to the light become troubled and decomposed, depositing sulphide of silver.

On the other hand, those which have been protected from light

* In practice, it will be understood that, on employing hyposulphite of soda, saturated with silver, the quantity of hyposulphite necessary for fixing is disseminated through a great quantity of water, and can act but feebly; while the silver salt is present in excess, as it were, upon a point, and cannot effect a rapid decomposition whilst the hyposulphite is super-saturated.

are not affected, even after the expiration of four or five months, but remain as limpid as at the time of their preparation.

This action of light, hitherto unknown, presents an aspect of the decomposition of the bath of the greatest importance; this, moreover, is so marked that in a room into which only yellow light is admitted, it ultimately makes itself felt, though in a much inferior degree than in full light. It is to this, much more than to the limit of saturation of the hyposulphite bath by silver compounds, that those solutions are due to which photographers give the name of "old hypo.;" and these solutions, as we have already shown in our preceding memoirs, are nothing else than agents in sulphurising the proof, and must in consequence induce, sooner or later, its alteration.

It follows that those photographers who are desirous of producing permanent proofs will perceive the necessity for fresh precautions, which we may sum up in the following manner:—

1. Operate as much in diffused and not in full light as possible, covering the dish in which the proofs are fixed with a mill-board or any other substance capable of intercepting the luminous rays.
2. Never employ the same portion of hyposulphite solution more than once.

A few words will suffice to explain the motive and value of these new precautions.

With regard to the first point: The light acts with such rapidity upon the solutions of hyposulphite of silver in hyposulphite of soda, that if they are concentrated, a few hours will suffice to render a precipitate of sulphide of silver perceptible. Now this precipitate, which forms in the midst of the liquor with great rapidity, is formed in contact with the printed proof. The extremely rapid decomposition of the double hyposulphite $S^2 O^2 Na O, S^2 O^2 Ag O$ in presence of water and under the action of light, is in our opinion an excellent proof. There is, therefore, a decided danger in having, even for a few hours, a fixing bath exposed to the action of light, especially if the latter is energetic, and the bath is already charged with silver salts. In fact, in this case the hyposulphite of silver, by its decomposition, causes in the very substance of the paper an almost simultaneous deposit of sulphide of silver and sulphur, which, in a manner more or less rapid, must influence its permanency.

As to the second point, it is perhaps more important than the first. Under the influence of the solar rays the solution of the silver salt in hyposulphite of soda undergoes, as we have shown, a decomposition; but if once commenced in the light this action seems to continue in the dark. Chemical analysis supplies a reason for this fact. On examining with care the composition of baths that have been exposed to the light, we discover that the precipitation of sulphide of silver is accompanied by the formation of acids of the thionic series, which, in the first instance, saturating the decomposed hyposulphite of soda, are not slow in becoming decomposed themselves, and give rise to fresh quantities of sulphide of silver, which, depositing in a successive and continuous manner, finish by removing from the bath all the silver it contains. Thus a fixing bath, containing salts of silver, after being submitted to the action of light during several hours, produces in the dark sulphurising compounds, thionates which, on coming in contact with a fresh proof, will cause at least a partial sulphurisation of the latter.

The preceding consideration explain and justify—at least *we* so think—the precautions we have advised, and which consist, on the one hand, of protecting, as much as possible, the solution during the fixing from the action of light; on the other hand, of never employing the fixing bath more than once.

The last cause of the alteration of fixing baths, and consequently of the proofs immersed in them, is due to the addition to the bath of certain acids, such as acetic. This method, advised some years since, but now little followed, need not occupy much of our attention, although noticed in this paper. A fixing bath prepared in this matter must necessarily entail a deposit of sulphur on the proof after the reaction.

$$(\delta)\ C^4 H^4 O^4 + S^2 O^2 Na O = C^4 H^3 O^3 Na O + SO^2 + HO + S.$$

This deposit, which forms with a certain tardiness, is more or less considerable, according to the proportion of acid employed; but it is constant, and the simultaneous presence of sulphur and silver upon the proof must cause, in a greater or less length of time, an alteration in the latter. This process must, therefore, be absolutely rejected.

Therefore, without prejudging the practical conditions of fixing (of which we shall treat in a special paper hereafter), we may state on the present occasion that the proof, on being taken from the printing frame, must be first washed in water, which, removing all the free nitrate of silver, diminishes the quantity of silver salt to be presented to the hyposulphite, and in consequence economising the latter; that the washing the proof in salted water, to convert the nitrate into chloride, is superfluous, as it in no respect diminishes the quantity of silver placed in contact with the hyposulphite, and in consequence does not retard the moment of saturation; that a washing with a solution of bi-carbonate of soda may be substituted with advantage; finally, that the bath of hypo. must only be employed for a limited number of proofs, for, owing to its saturation, and especially to the influence of light, its solvent agency may, after a certain time, be replaced by a decomposing action.

We shall return to this subject when we establish the practical conditions for properly fixing the proof.

After our experiments, we may say that the double hyposulphite of soda and silver acquires, in the presence of certain salts, such as nitrate of potash, table salt, &c., a great stability, which thus is found to justify the recently-proposed practice of saturating the hyposulphite bath with common salt.

PHOTOGRAPHY BY ARTIFICIAL LIGHT.

M. Wulff adopts the following method in working by artificial light:—He coats the plate with a collodion of the following composition:—

Alcohol at 40° *(centegrade)*	300 parts *(by weight)*.
Ether at 60° "	100 "
Gun-cotton	2 "
Iodide of ammonium	4 "
Bromide of ammonium	3/5 "

sensitises with a bath of—

Distilled water	100 parts.
Nitrate of silver	7 "

and develops with—

Distilled water	1000 parts.
Sulphate of iron	100 "

He employs a lamp similar to that constructed by Mr. Moule; but, to obtain the best results, he finds it absolutely necessary to reflect the light on to the object by means of screens covered with linen, coloured blue or grey. The following is the formula of the pyrotechnic composition he employs:—

Pure and well-dried nitrate of potash	3000 parts.
Flour of sulphur	1000 "
Powdered sulphuret of antimony	200 "
Powdered red orpiment	400 "

These are well mixed and afterwards passed through a sieve. About six ounces of this composition is placed in the pan in the middle of the lantern. This quantity will burn from ten to fifteen seconds, being a sufficient time in which to obtain a proper impression; but by augmenting this quantity both the intensity of the light and its duration may be increased at will. After having placed the sitter by aid of a lamp, the shutter of the plate-frame is raised, and the cap of the lens removed immediately the pyrotechnic powder is lighted.

STEREOGRAPHS.

Reminiscences of Scottish Scenery, by W. Woodward, *of Nottingham.*

(Concluded from page 241.)

In the Jedburgh Abbey series we have some highly interesting specimens, including, as it does, not only the Abbey itself, but several picturesque views on the Jed. No. 161 is a view of Jedburgh Abbey from the south-east, and exhibits the entire building as seen from the road. It is a structure of dressed stone, and has similar characteristics to others in Scotland which we have already noticed; in fact, it would almost seem as if they were built expressly for the purpose of ultimately forming picturesque ruins.

In No. 164 we have The Nave, looking west, and in No. 165 The North Aisle. The latter being an exceedingly "telling" subject in the stereoscope, it will no doubt be a favourite.

No. 168, On the Jed, is a pretty little picturesque view across a bend of the river, with the Abbey in the distance, seen between the trees on either side, and two or three figures reclining on the grassy bank; but the effect is a little marred by over-development of the negative.

No. 169, Bridge over the Jed, would be described by our French brethren as "leaving nothing to be desired." The execution is equal to the subject depicted, and that is not according any mo-

derate amount of commendation, for it is truly an exquisite "bit." The water occupies the foreground of the picture, with a surface as smooth as that of a mirror, in which the trees, bank, bridge, and distant hills are beautifully reflected—not as a duplicate turned upside down, but in a charmingly suggestive manner, being broken up and obscured by masses of rock protruding from the bed of the river, clothed with the humble vegetation so prevalent in similar localities. The bridge is a mere wooden structure for the accommodation of foot-passengers. On the right is a precipitous bank, "with verdure clad;" on the left bank are some lofty oaks, and the river in the extreme distance loses itself in one of those charming ravines which are so numerous in the Scottish Highlands—another specimen of which we have in the next that we shall notice, No. 166, GLEN-BURN, which is a delightful conglomeration of winding paths on rocky banks, with specimens of the oak, ash, beech, wild-brier, and bramble, in charming and picturesque confusion.

KIRKSTALL ABBEY contributes four illustrations:—No. 125, as seen from the west, where a good idea of the general design is gained; No. 129, from the *hospitium*, where mere fragments of the foundation are nearly deposed from their position by the encroachments of their active opponents of the vegetable kingdom; No. 127, *The Nave*, looking east, an "interior out of doors," as Pat would call it; and No. 123, *The West Door*, which, *more Hibernice*, consists of an arched entrance partially closed by a gate.

Although not properly belonging to the series, we find a few amongst them are no doubt associated by the artist in his mind with the others, inasmuch as he probably took them on his way home from the far north. Of these we shall notice two as worthy of mention, viz.:—No. 134, the east window of ST. MARY'S ABBEY, YORK, and No. 130, YORK CATHEDRAL from the south. The latter especially deserves commendation, it being a capital view of all the most important features of York Minster.

We fear that, unless Mr. Woodward is more favoured than his brother photos, he will scarcely return from his present year's trip, should he have made one, with his bag so richly stored as after his last expedition.

GOVERNMENT IN COMPETITION WITH PROFESSIONAL PHOTOGRAPHERS.

WE have to call the attention of professional photographers to a question in which their interests are involved, viz., the propriety of a Government Department undertaking the production of photographs of national property at rates below that at which they could possibly be published through private enterprise. This arises through a parliamentary inquiry that has lately been instituted as to the general management of the South Kensington Museum, during which certain facts were elicited as to the system on which the photographic department of that institution is conducted. As, however, a decision of the House of Commons on the subject shelves the question for a season, we can only ventilate the matter meanwhile, in the hope of eliciting such a discussion of the points involved as may lead to an unanimity of opinion and a defined course of action amongst those interested when the time arrives again to open up the subject. On the present occasion we shall give *verbatim* that part of the "Report from the Select Committee on the South Kensington Museum" that relates to the photographic department—viz., Section 12—and analyse in detail the evidence laid before that committee on future occasions.

THE SELECT COMMITTEE HAVE AGREED TO THE FOLLOWING REPORT ON SECTION 12:—

"12. The collections of reproductions by photography and casting have been made primarily to furnish models for the use of the eighty art-schools in connexion with the department of science and art: they are obtained from public collections at home and abroad. After providing for the art-schools, it has been thought right to give the public at large the benefit of the photographs at cost price, for the promotion of general art-education. The science and art department express a desire to avoid any competition with professional photographers by limiting their sales to photographs taken from Government collections, to which, except in rare and special cases, the trade is not admitted; but it has been objected by one commercial firm, enjoying peculiar privileges of admission to collections, and by Mr. Fenton, a photographer of eminence, that even such a limited sale by the department is an improper interference with private enterprise.

"There is an obvious distinction between copying and photographing pictures and works of art belonging to the public. Copying is attended by no very serious inconveniences, while photography almost invariably requires the removal of the object, deprives the public of the exhibition of it, exposes it in the light, to the risks of breakage, rain, &c., which can only be guarded against by great vigilance, requires a special apparatus of considerable bulk, and uses chemicals which are always unpleasant, and often dangerous. Mr. Panizzi shows that the only fire ever known at the British Museum was caused by the negligence of a photographer. Under such circumstances all the witnesses agree that a general right to photograph cannot be conceded to all like the right to copy. Mr. Fairbairn stated, that at the Manchester Art Treasures Exhibition the photographic professors were pests, and that it was found absolutely necessary to limit the privilege to one person. In order to execute photographs in public collections there must be a monopoly somewhere. If it be proposed to grant this privilege to a limited number of competent persons, as was at one time the practice at the British Museum, the difficulty arises, which was felt by the trustees, of deciding who is competent. Mr. Panizzi considers it 'a very difficult thing to determine who is competent,' and the trustees were forced to say, 'We will only admit our own photographer.' For a public department to attempt to determine this question in the case of every application would lead to constant difficulties and heartburnings. Moreover, the favoured persons having the monopoly among them might league among themselves to make the public pay an unfair toll for the use of their own property. These objections would apply all the more strongly to the appointment of a single private individual or firm, as the monopoly would be all the closer. The experience obtained at the British Museum, as well as at the South Kensington Museum, has led to the conclusion that the only feasible course for public interests is to employ one responsible public officer; and by harmonious co-operation between these two departments, one photographer is employed for both. A tariff of moderate prices is published, at which the public may obtain negatives, and print positives for themselves. Any publisher may thus produce and publish, at his own prices, any object in the British Museum or the South Kensington Museum.

"As respects 'positives' of public objects, the sale of them by the department to the public is limited to objects in public collections which it is not permitted to private enterprise to photograph, and to a price only covering the cost of production. Your committee consider that there is no other course so free from objections or so good for the public at large as the present system of the department. The printing of photographs stands on the same footing as the printing of parliamentary papers, and the publishers might, as well as the photographers, complain of the low price at which they are sold. If the price were increased, there is no doubt that the sales would be greatly diminished, and the spread of knowledge of parliamentary proceedings arrested. The trustees of the British Museum attempted to supply the public with photographs of objects in the British Museum, at the same time allowing their photographer the privilege of publishing, but they abandoned the system after considerable losses.

"Your committee have investigated fully a complaint of Mr. Scott, in respect of the photographs taken by him from Raffaelle's Cartoons. Mr. Scott complains that Mr. Caldesi was obstructed by the officer of the department of science and art in taking his photographs, and that he has been undersold by the department; but Mr. Redgrave proved that Messrs. Caldesi would have been unable to have produced any satisfactory photographs unless the department had permitted them to have the benefit of the removal of the Cartoons by their officer, and that as the sale of the Cartoons by the department cannot yet be said to be in operation, the apprehension of being undersold is at least premature. At any rate, the public have no reason to regret that Mr. Scott's suggestion of vesting in his firm an absolute monopoly of the photographs of the Cartoons has not been complied with. The arrangement by which a private was joined to an official photographer, was almost sure to lead to disputes, and should not be repeated."

APPLICATION OF PHOTOGRAPHY IN THE CONSTRUCTION OF MICROMETERS.

By CLARENCE MORFIT, *of the United States Assay Office.*

THIS is merely the reduction of a large scale of exact dimensions and divisions to a definite size suitable for microscopic instruments. A scale of ten inches, divided into inches and tenths of an inch, has been reduced in this manner to one-twentieth of an inch; thus making its smallest divisions equal to one two-thousandth part of an inch square. The method is simple, accurate, and economical. Moreover, the micrometer has the advantage of giving the exact measurement of the object in fractions of an inch, and at the same time determines the power of the microscope itself.—*Silliman's Journal*, Vol. XXX., No. 88, page 156.

[Mr. Maltwood, we believe, was the first to apply photography to the production of micrometrical scales, and described his method of producing a "finder" in the *Quarterly Journal of Microscopical Science*, Vol. VI. 1858. *Transactions*, page 59.—ED.]

ON PRODUCING THE IDEA OF DISTANCE IN THE STEREOSCOPE.

By JOSEPH BECK.*

IN a view taken through the camera no immediate foreground can be introduced: thus we lose in the photograph an important element in nature for the appreciation of size and distance. In reproducing nature we ought to supply some substitute. This can easily be accomplished. Take an ordinary glass transparent view, and look carefully at it: in some instances the foreground absolutely appears to project into the instrument; and never is it so arranged that the idea of the distance of the foreground of the picture from the edge of the stereoscope is given. Take now a black mat or card, with two holes so cut in it, that when laid on the view the right eye can see more of the left-hand side of the right picture, and the left eye can see more of the right-hand side of the left picture. It will then be obvious that the eccentricity of this mat will indicate a difference of angle; and in proportion as this eccentricity is increased or decreased, so the picture appears to advance or recede from the stereoscope; and as the view recedes and distance is given, so the appearance of the real size of nature is obtained.

If the plan is reversed, and the mat is cut so that the right eye sees less of the left-hand side of the right picture than the left eye, we can produce the appearance of the object standing up in the instrument, and in proportion as it approaches the stereoscope, so the size is decreased. In these cases there is no difference in the angle at which the pictures are taken, and yet such vast differences in the apparent size of the picture, showing that whilst the amount of difference of angle is a matter of comparatively but little consequence, the introduction of a prominent foreground, such as mentioned above, enables us to estimate the real size of the object viewed. The carrying out of this plan may be observed in the

* Abstract of paper read before the British Association, 1859, extracted from the official report, lately published.

mounting of Mr. Warren de la Rue's photographs of the moon. Had they been mounted in the centre of circles, they would have appeared as two-inch balls, with beautiful miniature volcanoes and mountain ranges traced upon the surface; but when mounted eccentrically, they immediately appear as floating far off in space, every hill and valley, mountain, volcano, or plain, assuming grand and imposing dimensions.

Letters to a Photographic Friend.

No. IV.

MY DEAR FRANK,

THEY say that short reckonings make long friendships; but I calculate that, in summing up my accounts with you, I run the risk of being cut for a bore, from the length to which they run; however, like a man of my word, at all hazards, I proceed to keep the promise contained in my last letter.

The next that I visited, after leaving Shew's, was Mr. Francis, of Great Russell Street, Bloomsbury. After examining the many ingenious and practical contrivances for which he is famed, including sliding cameras, bellows cameras, and stereoscopic cameras, portable tents, field boxes, clamp boards for plate cleaning, printing frames, steel rolling presses for putting a surface to paper proofs, polygonal lamp shades made of transparent photographs mounted in metal frames, and many little dodges too numerous to mention, I gave special attention to some glass dishes of very large size, which at once struck me as being very suitable for the preparation of life-sized photographs. The bottom and four sides, which are of glass, are very neatly and solidly cemented into a well-made iron frame: these may be made up to any size that glass is made to.

I also noticed a bath for a whole plate glass, of extraordinary lightness. It was made of thin mahogany, lined inside with pure sheet india-rubber; the top was arranged to be water-tight, and to hold a minimum of silver solution.

A packing-case, arranged to hold the camera, tent, and field box, was ingeniously contrived, so that it could readily be mounted on an axle carrying a pair of small wheels, and as readily unmounted, the axle-bar dropping into a groove across the bottom of the box, and then being fixed in position by two turn buttons, the legs of the tent serving as a handle whenever it may be desirable to push the "traps" before one.

Mr. Francis has so arranged a very neat little stereoscope that it folds up into a little box 1⅝ inches thick, to hold thirty slides.

Another arrangement, for holding a series of stereoscopic slides, consisted of a set of thirty frames, hinged on a central cylinder that rotated on an axle mounted in the centre of a drum-like case, into the upper part of which the two lenses were fitted obliquely, and in front of these a door opened to admit and reflect light upon the stereograph under examination. This contrivance is admirably suited for exhibiting stereographs in public places, or in class-rooms, where stereographs are used for educational purposes, and it is desirable to protect the slides from the handling of many inspectors.

Another contrivance was a frame wherewith visiting-card portraits are taken. It consisted of a frame divided into eight compartments, so that each in turn could be brought under the action of the lens by means of a double set of grooves at right angles to each other: by this means eight negatives may be taken rapidly in succession on one large plate. Of course, in printing sets of 50 or 100 visiting cards, a number of negatives are absolutely necessary.

Next in turn came Mr. Dallmeyer's new establishment, in Bloomsbury Street. Here I found an assortment of lenses suited for the general requirements of photographers, whether for portraits, groups, landscapes, or architectural views. In these the chemical and visual foci are coincident, and are free from aberration from the centre to the margin of the picture. The landscape lenses seem to be on the model of the late Mr. Andrew Ross, but the portrait lenses are constructed so that not only can they be used for views, architecture, and groups, by the introduction of suitable stops, but the front lens may be employed as a distinct view lens. The improvements Mr. Dallmeyer professes to have effected in this form of lens are:—

"*For Portraiture*—Greater rapidity of action over the whole plate, and nearly perfect flatness of field. *For Groups, Architectural Views, and Landscapes*—Perfect straightness of marginal lines, and a flat field; an increase of 15° in the angle of picture produced (this also expresses rapidity of action, and the so-called 'depth of focus'); greater universality of application of one instrument. Thus, for example, the No. 3 portrait lens, without any stop, will produce pictures on plates 6½ by 4¾; with a large size stop it may be used for groups on plates 8 by 6. With a smaller size stop it may be used for architectural views and landscapes (possessing the most perfect definition, flatness of field, and straightness of lines), on plates 10 by 8, which is equal to an angle of about 52°. By unscrewing the back combination, and replacing it by the front, it may be converted into an ordinary view lens, having a focal length of 16 to 18 inches, and capable of producing pictures 12 by 10. Every other size instrument has the same properties, and may be used in like manner."

It is recommended that a set of Waterhouse's diaphragms be used with each lens to obtain the above advantages.

His new stereoscopic lens is made after the same principle, and produces lines of perfect straightness upon a flat screen, with fine definition, and includes an angle of nearly 60°, thus producing a much more striking stereoscopic effect. As a double combination portrait lens it has a focal length of 3½ inches; whilst as a landscape combination it has a focal length of 6 inches. Mr. Dallmeyer has not adopted the orthographic form of lens, but in place of it he intends to introduce a triplet: the first one so constructed he gave me an opportunity of examining. This, as its name implies, consists of *three* achromatic combinations, with cemented contact surfaces, the total number of reflecting surfaces being thereby the same as in a portrait combination. The front and back combinations are both *positive*, and between these, in the position of the stop, is a *negative* combination. The ratio of diameters of front and back combinations is as 2 : 3, and the diameter of the negative combination is ⅔ that of the front: the ratio of aperture and focal length is as 1 : 15, which may be increased at pleasure by means of suitable diaphragms. The angle of picture included is about 56°. This lens, with a focal length of 17 inches, covered a plate 15 by 12 inches, with the lines straight up to the corners.

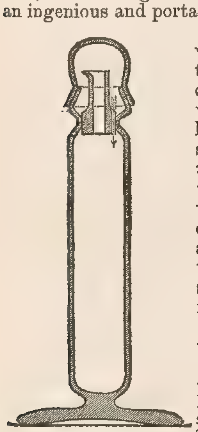
This triplet, as I said, is intended to replace the orthographic form of lens, and is therefore properly to be employed for architectural views and copying; but as each of the three combinations are actinic *per se*, the middle lens may be removed without interfering with the actinic adjustment of the two other combinations, and may in this way be employed for portraiture. Although with a comparatively smaller aperture it works nearly as fast as the same maker's portrait lens, on account of a reduction by two in the number of reflecting surfaces, it does not present so flat a field.

Mr. Dallmeyer's new lens has little in common with Mr. Sutton's "symmetrical triplet," the negative arrangement not being a single uncorrected lens, but an achromatic combination of such form and focal power, as is subservient to the corrections of the eccentrical pencil and the production of a flat field, with an aperture quite as large as can be used with the orthographic form of lens. The great drawback to Mr. Sutton's triplet is the very small aperture he employs in obtaining the necessary corrections.

Having heard of the neatness, compactness, and economy of the metal-plate boxes manufactured by Mr. Miers, I called at his workshop, at 15, Lamb's Conduit Passage, Red Lion Square; but although he does not pretend to make any show, as he chiefly lays himself out to supply the wholesale trade, he gave me an opportunity of inspecting his various patterns for small and large plates. These boxes are made in bronzed zinc, grooved in such a way that the plates lie so close together that 100 only take the space that 50 would occupy in a wooden one, and are hinged in such a manner that, whilst they are perfectly impervious to light when shut, it is impossible for the lid to open by accident or unpremeditatedly. As the metal has no disposition to harbour damp or give off terebinthinous exhalations, these boxes are in everyway preferable to wooden ones for storing dry plates or negatives, especially now that they may be obtained of Mr. Miers at about the same cost. I do not think that there can be a question but that metal will entirely supersede wooden plate boxes ere long. I have purchased some of these boxes for stereoscopic dry plates, to hold one and two dozen each; also another to store two dozen glasses half-plate size.

The next on my visiting list was Mr. Thomas Ross, of Featherstone Buildings. As he constructs photographic lenses after the principles laid down by his much-esteemed father, that veteran optician, Andrew Ross, whose view-lenses, I take it, no one can beat, I found nothing to call your attention to in the shape of optical novelties; but I may mention that he has introduced a neat method of uncapping a pair of twin lenses simultaneously, when they are fitted to be adjusted at varying distances. The two lenses are so mounted that they can slide nearer to or farther

from each other, according to the will of the operator, in a horizontal groove in the front of the camera. The apertures of the lens tubes are closed by means of brass plates working on pivots, as in French lenses: to the bottom of each plate a small binding-screw is hinged, through both of which a small steel rod passes, thus connecting the two shutter plates, as they may be called, and the rod is clamped at whatever distance the lenses may be apart. By pulling one end of this rod of course both shutters are drawn aside at the same moment, and by a contrary motion they are both simultaneously shut, their exact position over the apertures being secured by means of stop-pins. It is curious to notice how most of the camera makers are at one and the same moment giving their attention to the perfection of the bellows principle, and securing stability at the points of weakness. Mr. Ross has just perfected a form of camera which I will endeavour to make clear to you. The base-board is framed, so as to allow of a telescopic extension, by means of an endless screw. To this is clamped the two mahogany frames that carry the lens and plate-holders respectively, the middle portion of the body being made collapsable. The peculiarity, however, of the camera consists in the arrangement for securing a swing back motion, with economy of space and workmanship, which is thus effected:—The back, into which the plate-holder slides, is not more bulky than a common camera; the bottom is attached to a wedged-shaped piece of wood that fits into a wedged-shaped cradle (X), in such a way that when a rod with a clamp-screw is passed through an axial aperture, common to both pieces, it forms a powerful hinge the width of the camera. By this contrivance *the top* of the plate can be advanced towards or withdrawn from the lens. "The cradle" is attached to the base-board by means of a pivot passing through its centre, and thus another motion at right angles to the first is obtained, so that the plate can be adjusted to the exact focus of an orthographic lens: these motions, of course, are facilitated by the bellows construction of the middle portion of the body. Rigidity is given to the entire arrangement by means of two telescopic rods, placed one on each side of the camera, having at each of their extremities pins, to which freedom of motion is given by a ball and socket attachment. The two pins of each rod are pushed into sockets inserted in the front and back frames of the camera, the inner and outer tubes of the telescopic rods are pushed as far apart as possible, and then clamped by means of screw heads, thus rendering the upper points of support perfectly tort. The camera that I examined was for plates 10 by 8: the dimensions of this were 12 inches high, 13½ inches wide, and 6½ inches thick when the back and front frames were brought together. The telescopic sliding motion of the base board allowed of a range of focus of from 6 to 18½ inches. The orthographic lens, focussing lens, tripod head, and all the screws and fittings, pack into a box that fits into the belly of the camera—all, but the legs, pack into a leather case, and the weight then does not exceed 15½ lbs. This is certainly an ingenious and portable form of camera for plates of large size.



As I was near to Bourne and Taylor's glass warehouse, in Castle Street, Holborn, I called to examine a new form of collodion pourer, christened "THE COMETLESS:" as a sketch will assist your comprehension of its form I give one. The inner part of the neck is stoppered with a lipped tube through which the collodion passes on to the plate. You will perceive, from the construction, that this is the only point on which the collodion can dry, an accident that can hardly occur, as it is kept in a solvent atmosphere of ether when the bottle is capped, and if any film should form on this lip the tube is readily removed, so that it may be cleansed. Air is admitted to the body of the bottle to allow the collodion to flow, by means of a groove, ground in the stopper part of the tube at the point indicated by the arrow. I should fully expect this to answer the purpose for which it is intended.

At this point I turned hotelwards, but on my way I looked in at Mr. Ladd's, the optician's, in Chancery Lane, who, however, is more known to microscopists than to photographers; but, as I expected, I found a goodly collection of micro-photographs of the best execution. If you require *a cheap* form of microscope for viewing such objects I do not think you could procure a better one for the purpose than that he supplies at fifteen shillings. Of course, if you wish to indulge in a more expensive instrument he will be happy to meet your views; and one model, got up for students after the suggestions of Mr. Brooke and Professor Busk, vastly took my fancy as a practical instrument. I am off again to-morrow in prosecution of my exploring expedition.

So believe me,

Yours, "Eastward ho!"

SIMEON HEADSMAN.

Foreign Correspondence.

Paris, August 27, 1860.

I HAVE lived enough in England to know the unfavourable opinion which is there generally professed for honorary distinctions in the form of stars and ribands. You are disposed to look upon them as toys, fit only for satisfying the vanity of trivial minds. Though, from a certain point of view, you are not, perhaps, altogether wrong, yet it is not less true that, in our country, where the thing is looked at in quite another manner, such rewards are powerful incentives to emulation; indeed, we are indebted to them for many an act of heroism, for many important labours in science, in art, in literature, in industry, for many great and useful discoveries,—all which things are nowise hurtful to the glory of the country. They serve also to measure the importance assumed by any given science, art, or industry. From such twofold point of view the honours of this kind accorded to photographers have a welcome meaning for all those in this country who interest themselves in the new art. For several years past no list of nominations has appeared in the *Moniteur* on New-year's day or the Emperor's *fête* without containing the name of a photographer. First, there was M. Nièpce de Saint Victor, whose labours you well know; Blanquart Evrard, the author of the earliest manuals and the first photographic printer; then Maxime du Camp, an amateur, already knighted as a literary man, who was named officer for his Egyptian and Syrian views; then Salzmann, author of a collection of views from Palestine; Martens, one of the first who practised the albumen method, and whose pictures still bear comparison with the most perfect productions af the present day; M. E. Delessert, a distinguished writer and able photographer; Braun, the photographer of flowers; finally, on the 15th August last, Baldus, who reproduced the new Louvre, during its construction, piece by piece, and stone by stone. Besides this immense and successful labour, the most important that photography has been officially called upon to execute, Baldus is the author of a considerable number of works, remarkable alike for their beauty of execution, the artistic feeling which marks them, and for their colossal dimensions. You will, doubtless, be surprised at not finding in the list certain names which should hold the first places: the name of Claudet, for instance, who, since the origin of our art, has so perseveringly contributed to its progress, whose studies have been so useful, and who has obtained so many triumphs; that of Ferrier, the first who spread a taste for the stereoscope in France, with his beautiful views on glass, hitherto unexcelled, and who thus created one of the most fruitful applications of photography. We deeply regret such delay in the accomplishment of an act of simple justice; but we are confident that reparation will not be long retarded.

If I have dwelt at some length upon these facts, it is because with us they are important. The same distinctions being bestowed upon photographers as upon men of science, literary men, and artists, it is evident that photography is not considered as a series of mechanical operations requiring but the bare dose of intelligence necessary for seconding the instruments and the chemical reactions; and that is a noteworthy conquest, for it was not always so.

You will, I trust, allow me to say a few words with respect to a letter in your last number, signed "P. Warbeck," and headed "A Photographic Miracle!" seeing that it indirectly touches myself; for, both in the *Moniteur* and the *Lumière*, as well as in your Journal, I have spoken with praise of Woodward's apparatus, of Bertsch's automatic camera, and of the photographic ink. If your correspondent is a serious man, I may perhaps tranquillise him by the assurance that his outlay is not useless, and for this reason:—he will always be free to operate with the old processes and the old instruments; but that will not prevent him from procuring, if he thinks fit, photographic ink and Bertsch's camera, which will certainly render him great services. I am not aware that it has ever been asserted that, with this new apparatus and new bath, a mere

tyro can, without preliminary study, become a clever photographer. That would be absurd; and those who would say so would lower photography to the level of mechanical operations, in which the instrument would be everything and the intelligence nothing. It *has* been asserted, and truly asserted, that a man of taste — an artist — might, by studying the length of exposure, obtain good pictures upon glasses prepared beforehand, and developed on his return. It is clear, however, that it is then the preparer who must be clever; and if your correspondent has such an one, and is himself possessed of artistic feeling, nothing hinders him from employing Bertsch's automatic camera with advantage. As to the photographic ink and Woodward's solar camera, I can assure him that they have given results which will not be readily disparaged by those who, like myself, have had them before their eyes. If "P. Warbeck" meant to joke, he will allow me to remark, that he criticises at least two things that he is not yet acquainted with, for neither the photographic ink nor Bertsch's apparatus have hitherto been tried in England. When we speak of an art and a science still so near their origin, and which have yet so many improvements to realise, we ought not, I think, to be in a hurry to criticise new things, especially when we have not maturely examined them. It is in such cases that the most entire impartiality is indispensable. Your correspondent will, I trust, pardon these frank observations coming from the veteran of photographic journalism, who has seen the birth of many new processes which, though often lightly esteemed at the first, have brought fortune and a name to those who adopted them. I will merely cite, as an example, the albumenised collodion method, the original description of which my dear and much-regretted friend, Taupenot, wrote one evening at my house, while he told me, with discouragement, of the miserable reception it had met with from those to whom he had spoken of it. At present some of those very persons employ no process but this, which has helped them to attain results both beautiful and profitable.

Some additional communications have lately been made on the subject of the photographic observations of the eclipse of the 18th of July. Father Secchi, director of the Observatory of the Roman College, has reported the results of the observations he made in Spain, with the co-operation of an amateur, M. Monserat. Besides the numerous images of the whole sun, fourteen enlarged pictures of the phases were made, and five pictures of the natural size of the focal image of twenty-three millimetres, representing all the phases of the phenomenon. The exposure was very variable — from three to thirty seconds. All the images are over-exposed in the protuberances, but the corona has an intensity which differs according to the time. The force of the light from the protuberances is such that one picture is triple from the glass having received a jerk. MM. Maxwell Lyte and Michelier have also forwarded to the Academy a series of images of the eclipse, obtained by them on the southern side of the Pic du Midi, in the Pyrenees. ERNEST LACAN.

New York, August 7, 1860.

The American temper towards photography is peculiar. People here do everything as a business—I mean everything which exacts labour of mind or body. We have pleasures enough, but they are only the extemporaneous *dolce far niente* of concerts and theatres, or the occasional uproarious frolic of an excursion, pic-nic, or political *barbecue*. No one amuses himself deliberately — no one makes a system of amusement, putting his whole mind to it, and pursuing it to a distant end. Amateur artists or artisans are not to be found; we think of Louis XVI., spending his leisure in his smithy, as a fool.

The reason of this state of things is chargeable perhaps on our democracy, or general equality of condition. Labour for money is a habit and necessity for all. If wealth is accumulated in a family, it is only by a constant persistence of industry, which gives no opportunity for the cultivation of habits of study, or practice of the arts of solid refinement and pleasure. The wealth of a family is dissipated by its next generation. In Europe you have families which for centuries, by law, have been free from the ordinary cares of living, and inherit the habits of study and refinement of a long line of ancestry: out of such come spontaneously amateurs of the arts, who diffuse among their less-favoured neighbours their own tastes and habits. Your government—also patrons of science—and your many royal societies and academies all tend to give a dignity and popularity to the pursuit of knowledge for its own sake which our American masses know nothing of. The common measure here of all kinds of worth is the dollar.

Our American condition of things, however, has its advantages. The average advancement of knowledge and comfort is here higher than in any other country. The American mind is quick to apprehend and the hand to execute. In all manner of work whereon the prize is in our estimation worth the winning, we shall beat you. Show an American when there is a reasonable prospect of business, and he needs no advice to embrace it. We have not originated here any of the photographic arts, but we have done much towards putting them in a useful shape; very many of the little details which are elements of success in practice are due to us.

Photography was first made a business in New York, and they were New Yorkers who inaugurated the business in London. We have no Daguerre, Talbot, Archer, or Hardwich here, but we have the men who can put their ideas into action. There is no great demand here yet for philosophers, but when it comes it will be supplied.

So far prefatory; and it hath a tone somewhat apologetic, perhaps boastful. But it is a fair expression of American sentiment on such subjects; and I suppose you want the picture of photography in America to be wholly and genuinely an American production.

Now in future I propose to tell you just what happens here, what we are doing, and how we do it.

I have several matters of photographic interest at present, but prefer to defer them, in order that the practical facts may appear without any of the doubts or prejudices which may be incident to this letter. CHARLES A. SEELEY.

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

SOLAR PHOTOGRAPHY.

T the Editor.

Sir,—In your last number your Paris correspondent gives a notice of what has been done by French *savans* in relation to the late eclipse. Among others, he speaks of M. Vernier's photographs, who, he states, "has sent me three, which, although of small size, give a very exact image of the sun at three different periods of the eclipse. *They are all surrounded by a halo*, the cause of which M. Verrier [*query* Vernier?] seeks in the phenomenon itself, and which, according to the adepts in photography, is to be explained by the simple fact that the operator made use of an objective with too large an opening."

Your correspondent does not state how large the aperture was; but in all my experiments in solar photography I have invariably found the halo alluded to, although I have reduced the aperture to one-sixteenth of an inch.

Mr. De la Rue alludes to some appearances in the photographic plate which were not observed through the telescope, showing that photography will register phenomena too delicate for the eye to detect.

The result of my own experiments, together with those of others, confirmed by your correspondent's notice of M. Vernier's photographs, induce me to believe that the halo or corona is always present around the sun, but the dazzling brightness of the orb itself destroys the power of the eye to discern it, while the introduction of coloured glasses obscures and renders it invisible.

During a total or annular eclipse, however, it becomes apparent in consequence of a dark body being interposed of a size sufficient to stop all, or nearly all, the direct rays.—I am, yours, &c.,

London, 17th Aug., 1860. W. HISLOP.

[Of the several specimens that we have had an opportunity of inspecting (not those of Mr. Hislop), all that show a halo appear to us to have acquired that appendage from errors in mounting the lenses employed. In all instances the "halo" is more or less detached from the body of the sun itself, and if it were a true envelope to that body we do not well perceive how that effect could arise.—Ed.]

TONING.

To the Editor.

Sir,—Hitherto my positive printing (which, however, has been only in rather a small way) has been all toned with the old bath of hypo.,—silver and chloride of gold mixed. That seems now to be no longer trusted for permanency, though in my hands it gave a good colour with very little trouble, and I see no appearance of change. Has not bad washing had something to do with its bad repute? Relying on your kind help (for no one can look at the last page of the Journal and doubt either your willingness or ability to assist) I have ventured to ask what advantage Maxwell Lyte's process has over some which seem less troublesome—Bayard's, for instance (No. 85, p. 11)? and if you practically know anything of Legray's and Jobard's (No. 91, p. 85)? Mr.

Leake (No. 105, p. 270) thinks the bath of hypo. and gold best, but without any silver, and even gets rid of the free nitrate. A friend recommends the carbonate of soda and gold, and the sulphur bath for Eusebius is something altogether different: between them all I am fairly puzzled.

If Maxwell Lyte's is on the whole most effective, please be good enough to say if the solution of *phosphate* of soda and the gold will keep, as I see the *carbonate* of soda and gold should be mixed a quarter of an hour only before using. May I also trouble you further as to what one grain of gold will tone? I think I have seen stated that it will tone one full sheet, $22 \times 18 = 416$ square inches, but then there seems great diversity of opinion.

In the *Liverpool and Manchester Photographic Journal*, No. 16, p. 204, James Alexander Forrest says:—"Make a solution of gold, three grains to one ounce of water, and three grains carbonate of soda; mix half a *drachm* of each, which is sufficient for a dozen proofs 9×7." Should it not be half an *ounce?* And Mr. Leake (No. 105, p. 270) says, a grain will only tone two proofs 10×8: that seems the two extremes. I suppose, as usual, the truth is somewhere midway with you and Mr. Hardwich, though on reference I find he only makes it tone from 240 to 250 square inches. I should feel very greatly obliged if you would set my mind at rest on these matters.

For the many hints and great pleasure I have derived from your Journal,—I am, yours, &c., FIX.

[We always try to aid our correspondents, and if we are at a loss we candidly say so. If all would refer to "chapter and verse" as you do, we should have much labour spared us. Bayard's toning bath is essentially one of *sel d'or* (double hyposulphite of gold and soda), with an alkaline chloride added: it therefore tones by depositing gold, it is true, but the gold is deposited by *sulphuretting the silver;* hence we do not think it so good as Maxwell Lyte's, which acts rather by *substitution* of one metal for the other. Jobard's and Legray's methods are both apt to degrade and even to destroy the half tones without the greatest possible care; and, as to trouble, they both require much more than Maxwell Lyte's. Every one has a right to his opinion, but we know that the hypo. and gold bath is *faulty in principle,* and therefore to be avoided. The soda and gold is good, and acts in precisely the same way as Lyte's bath; but it has the inconvenience, if too strong, of dissolving out the size from the paper.

The solutions of phosphate of soda and chloride of gold should be kept in *separate* solutions, and mixed just before use, adding a sufficiency of water to increase the bulk. Mr. Forrest manipulated in a peculiar way, —not in a bath; hence his solutions are strong. The quantity given is correct. One grain of chloride of gold, if properly used, will tone a sheet 22×18 inches.—ED.]

DRY PROCESSES.—DARK TENT.

To the EDITOR.

SIR,—A good modification of the collodio-albumen process will, I am sure, be gratefully adopted by many lovers of dry processes, and you will confer no small boon upon them in furnishing it. But meanwhile I do not think any one need "reserve his pledges," seeing that such worthy and tried confederates are in the field. The collodio-albumen process, as used by Messrs. Sidebotham, Mudd, &c., is surely neither tedious or uncertain if rightly practised. I have tried nearly every preservative process that has been suggested, and have obtained fair results from nearly all,—even from linseed, quince-pips, raspberry syrup and vinegar. But I prefer the collodio-albumen to all others, for the easiness with which it is manipulated, its sensitiveness, and the certainty of its results. I use the formulæ of Mr. Sidebotham or Mr. Mudd, and proceed thus:—After sensitising, remove to a vertical bath of distilled or rain water while coating the next plate, then wash under a tap or from a jug; albumenise and stand up to dry. After preparing, say a dozen plates (all this I do by subdued daylight), I dry thoroughly before a fire or over a spirit lamp, then stow away in mahogany boxes. As short a time as convenient before exposure I warm the plates again, sensitise in aceto-nitrate bath, and wash, till greasiness disappears, with common water. I never see a blister or stain, or fail to get my picture, when I have strictly followed this course, and am not clumsy or careless in the development.

I set out lately from London provided with a good supply of Fothergill plates, prepared strictly as Mr. Ackland prescribes, gum plates (Mr. Hardwich's formula), and Taupenot. I have had good success with all, but the best with the last; and in a series of comparative experiments I found it the most sensitive. I inclose you a specimen of each, printed under great disadvantages, and toned with bad materials procured in the country.

Mr. Ackland's and Mr. Hardwich's processes are both very good (the former the more sensitive, and having greater keeping qualities), but they require a peculiar collodion, and it is easier to spoil the plates, while there is scarcely an appreciable difference of time between the preparation of either kind and the Taupenot (except in the heating of the latter to prevent blisters). Let, then, the old favourite have our votes. If he can better adapt himself to our impatience and other infirmities, doubtless we shall not be sorry; but in any case let him not be deserted, for there is not his equal.

When next "Simeon Headsman" travels from east to west, let him stop in the Strand, and ask Mr. Rouch to show him the small "dark chambers" which he supplies for stereoscopic plates (and which will do well for whole plates). It is really a portable box, holds everything you want on the field save two tripod stands, and opens into a most comfortable chamber, with luxurious room and abundance of rigid surface. I have inspected every tent that has been advertised, and can confidently recommend this one as in all respects the best.—I am, yours, &c.

A CLERICAL AMATEUR.

P.S.—I should have stated, in favour of Mr. Hardwich's process, that it gives very intense skies, and develops nearly as rapidly as wet collodion.

[The specimens enclosed show that our correspondent is a skilful and careful manipulator. The two from the plates prepared with gum are very delicate and pleasing, more so, in our opinion, than those from the two Taupenot plates, though we have no fault to find with that in which the operator is himself included. All of the samples are good, however, and much depends upon the special requirements of each operator as to convenience of working before one can decide which process should be recommended. We think, however, that our correspondent can hardly fail to admit that Mr. Petschler's discovery, published in our last, really is an improvement upon all the processes, and the principle would probably hold good with many of them. We like to follow the advice of St. Paul:—"Prove all things: hold fast that which is good."

We have no doubt that the indefatigable "Simeon Headsman" has visited the establishment mentioned, and that we shall hear something about the favourite box that is a tent, or tent that is a box, ere long.—ED.]

DIRECT POSITIVES.

To the EDITOR.

SIR,—I have for some considerable time back taken great pleasure in what I wonder much is not more practised by amateurs, viz., taking views of scenery as direct positives on glass. In colour (having the tone of a lead-pencil drawing) and in sharpness of definition, in consequence of the very much finer texture of a good collodion, they exceed anything that can be done on paper, bearing an examination with a powerful magnifying glass—when, indeed, the effect is quite stereoscopic.

Of course they cost much less in *time, trouble,* and *money* than prints from negatives would, and to me at least, and I am sure to many amateurs, these are most important considerations. Besides, they are far more permanent than positives; and if more than one copy of each view is wanted, say to give away to friends, it is very easy to take as many *direct views* as may be required at once when taking the first.

Hitherto I have always worked with the wet process; but if I could learn a suitable and certain *dry process* for these direct positives, it would save a great deal of trouble, and often expense, in carrying dark tent and apparatus; and besides, if I had only to carry a light camera and stand, a box of dry plates and a yellow calico bag, I would get very many more pictures in the year.

Perhaps you would kindly suggest something that would suit my requirement. Any hints given in the next number of your Journal will be thankfully read by me, as I hope shortly to go from home, and have the opportunity of photographing some beautiful scenery in Ireland—for instance, a splendid panorama of mountains from a peak three thousand feet high, which I resolved to take the last time I was up there last year.

What developer do you recommend for instantaneous positives of children, animals, &c.?

With many thanks for the pleasure and advantage derived from the perusal of your Journal these last two years, I am, yours, &c.,

Harrogate, August 9*th*, 1860. A CURATE.

[We cannot agree with your notion that direct positives are superior, or even equal, to good paper proofs from negatives; and we would very much prefer a good negative to the best glass positive in the world: but *chacun à son goût.* We have already suggested a course of operation to you, as your letter reached us too late for insertion in our last; but as there are, as you say, possibly others who think with you, we repeat it more at length, and with your communication. We only offer a *suggestion,* not practical experience. We would try the plan of immersing the sensitised plate after removal from the nitrate of silver bath to one containing a solution of bromide of potassium, about one grain to the ounce of distilled water, and then, after washing slightly, allowing it to dry. We do not think any preservative solution advisable, as organic matter tends greatly to degrade the tones of a positive. We select a *bromide* to neutralise the free nitrate of silver, because it is, like the chloride, capable of being reduced by the action of light; and we have found that the union of iodide and bromide of silver is advantageous for positives, and that the two salts are more sensitive to the actinic influence than either alone especially when dry. We would use the proto-nitrate of iron (or a mixture of it with the proto-sulphate) as a developer, first, however, immersing the plate in a weak nitrate of silver bath. We do not think that there would be in this case any serious difficulty arising from the impermeability of the collodion film. We should clear with cyanide of potassium, to preserve the whites as pure as we could obtain them.—ED.]

OVER-ACTION OF DEVELOPER.

To the EDITOR.

SIR,—I have been sadly troubled of late with a sort of mistiness over my positive plates, never perceivable in ⅛ or ¼ plates, but almost always in ½ and ⅟. I find it the same with crown glass, colourless sheet, or patent plate. I sensitise in a bath of thirty grains; develop with iron; fix with cyanide; and after washing, the whole surface is covered with a something resembling a very thick coating of dust, which can be wiped off without disturbing the film. Can you kindly inform me, in your next Journal, whether the fault lies in the bath or the collodion, and how I can remedy it?—I am, yours, &c., MISTY.

[The action of your iron developer is too energetic, and acts upon the silver salt to some extent, even when *not* exposed to the light: this is possibly assisted by accumulation of ether and alcohol in the bath. The remedy for this inconvenience we think you will find simply by adding a few drops of a *weak tincture of iodine* to the collodion—enough to give it a pale sherry tint. Its action is to produce, in contact with the film, a very small quantity of nitric acid, which, we think, you will find more effective than adding the latter to your bath. A few grains of iodine in an ounce of alcohol will make your tincture; the quantity is not material, the colour produced in your collodion being your guide.—ED.]

FOCUSSING.

To the EDITOR.

SIR,—I do not find in any of our "A B C" books or Manuals of Photography any plain instructions for focussing a landscape, and shall be much obliged if you will kindly reply to the following queries:—

1. Supposing you wish to take a landscape, comprising foreground, distance, and middle distance, with an ordinary view lens and small stop, should you focus with the full aperture at first, inserting the stop afterwards?—and, if so, should you make any alteration after inserting the stop?
2. Should you focus for the foreground distance or middle distance?
3. Is there any practical objection to Mr. Sutton's plan of *marking* your lens to indicate a particular focus?—I am, yours, &c.,

A SUBSCRIBER.

[1. With all ordinary lenses the size of the aperture slightly changes the sharpest focal point, or in other words, the circle of least confusion is located at a somewhat different longitudinal distance from the lens; but if you get a sharp focus with a large aperture, and insert a smaller one, the sharpness will be further increased, though not to the utmost extent possible with the smaller stop. It is therefore better to focus with the aperture that you intend to employ for taking the picture, unless the illumination is too faint for you to see what you are about. Remember, also, that reducing the aperture very slightly lengthens the focus.

2. The point for sharpest focus must depend upon your subject. *The principal object* should be that selected; but if you have important objects in nearer or more distant planes, a compromise will possibly be requisite. If they differ very widely, a small aperture is the only remedy; but still the principal object should be that most sharply focussed.

3. No objection to marking your lens for the focus of a very distant object; but we perceive no utility in it, as we should never think of taking any view without specially focussing.—ED.]

☞ **The Publisher, in reply to continual inquires, begs to inform present or intending Subscribers to this JOURNAL that no difficulty exists to prevent its being received on the respective days of publication (viz., the 1st and 15th of each month) in any part of Great Britain and Ireland. It is printed in sufficient time to be despatched by the Publisher, Liverpool, or by the London Wholesale Agents, so as to reach the most distant Subscribers and Agents on the above days. Orders sent direct to the Publisher, accompanied by a remittance (if by post-office order, made payable to Henry Greenwood, 32, Castle Street, Liverpool), or to the London Wholesale Agents, Messrs. E. Marlborough and Co., 4, Ave Maria Lane, E.C., will receive immediate attention. Foreign Subscribers and Agents can also be supplied in the same manner by paying the additional postage charged by the Post Office. Orders given through Country Booksellers are carefully executed by Messrs. Marlborough and Co., as above, or by the Publisher, Liverpool.**

ANSWERS TO CORRESPONDENTS.

PRACTICAL INSTRUCTIONS ON COLOURING PHOTOGRAPHS.— *Those of our readers — and they are legion—who take an interest in Mr. Wall's valuable and interesting articles on Colouring Photographs, must bear with another disappointment and delay in the continuation of the series. An unavoidable accident, at the moment of going to press, has prevented the insertion in this number of the continuation of Chapter VII. It shall appear in our next.*

* * *—It is a cause of much regret when we find it impossible to reply to any of our correspondents in the number next published after receiving a communication; but we must remind those who delay their inquiries till the last moment, that we *publish* on the 1st and 15th, and that an interval of two to three days must necessarily elapse between publication and "going to press," which in our case is somewhat increased by Post-office arrangements. Those friends who wish for replies "in our next" must, therefore, continue to let their letters reach us *not later* than the first delivery on the mornings of the 12th and 28th respectively; and if any references are necessary, or elaborate replies required, at least one day earlier.

JUDICIOUS.—May be so. Try again. But we doubt if you will fare better.

ARGENTI NIT.—Johnson and Mathey, Hatton Garden, will supply you.

S. F. L.—We have not received any.

SAMSON.—We prefer good "*flatted crown*" glass for small plates.

AN INTENDING AMATEUR.—C. J. Hughes, Oxford Street; Murray and Heath, Piccadilly.

J. CROOK.—We have not seen the apparatus you mention.

T. WHARTON JONES.—Received with thanks. Notice in our next.

JULIUS.—The developer requires a little more acetic acid added to it, or it would not turn muddy so soon as you describe.

INVERNESS.—See Messrs. Petschler and Mann's paper in our last number. It describes the very thing you want; nothing can well be more perfect for a continental trip.

H. A. P.—We will not be led into the expression of an opinion with only half the case before us: we must have both sides of the question to enable us to judge.

HENRY J.—You will get it at Murray and Heath's, Piccadilly. We do not know if any other manufacturer produces one.

GREENHORN.—Get rid of it at any price; you are, however, rightly served, for you ought to have known better.

S. L. D.—We do not believe a word of it, and have no doubt that it is a gross and malicious libel. We think better things of English *ladies*.

WEAK.—Your collodion is not sufficiently iodised; add about two grains iodide of cadmium to each ounce.

PHOTO-FELIX.—You are an exception to the rule, then, for ill has been the fortune of most this year, as regards weather. Frith and Hayward, of Reigate, will undertake what you want, we have no doubt.

F. P. (South Wales.)—We are not quite sure about the initials. You had better apply to Mr. Mudd, of Manchester, or Dr. Norris, of Birmingham, for a supply. Do you never read the advertisements in this Journal?

OLIVER N.—Cyanide of potassium to remove the iodide, &c., of silver from direct positives, is almost an absolute necessity, as the resulting tones of the lights, after using hypo. instead for fixing, are very materially degraded.

F. W.—A pneumatic holder will remove all your troubles. Shew, also Hughes, in Oxford Street, or Murray and Heath, Piccadilly, will supply you, and all are close at hand to you.

MARGARET.—You will find that the india-rubber finger stalls (which cost about 3d. each) will protect the fingers when printing and toning, if you only use common care not to dip them too deeply into the solutions.

WOULD-BE OPERATOR.—We will gladly assist you, if you only give us the means; but when you ask "what camera we recommend?" how can we do so without knowing the purpose to which you wish to apply it, and the size of the pictures you desire to take?

ROBERT L. HUME.—A good glass bath is the best. We have a hard earthenware one in use that has stood well for three years: it was made for a cell for a galvanic battery, and cost six shillings.

R. GORDON.—Messrs. Forrest and Co., Lime Street, Liverpool, are the most likely people to procure what you want. Write direct to Mr. Forrest: he is an enthusiastic photographer, and will certainly respond to your communication.

F. M.—Your sensitising bath is most likely partially exhausted. Add to it about twenty grains more nitrate of silver to each ounce, and you will not find your paper assume the mottled appearance of which you complain.

DREADFUL MUFF.—It is said that "a fault admitted is half cured." Never mind the trouble; it is not half so bad as spoilt prints. We prefer Maxwell Lyte's, but the other is good.

F. M.—Waste collodion poured on and immediately rubbed with a piece of rag will remove the varnished film as rapidly as anything that we know. Placing the plates in hot water is a good plan, and rubbing with a cork.

F. B.—The fault lies in the nature of the collodion, which is too contractile, and when re-moistened, expands more than the albumen. The best chance for the rest will be to place the plates for ten minutes or so on a *hot* brick, prior to development, to coagulate the albumen thoroughly, and make it adhere firmly to the plate.

CHLORIDE OF SILVER.—Silver being five shillings per ounce, the chloride should be worth about three shillings and sixpence; but as there would be the labour of reducing it to take into account, we presume that about three shillings per ounce would be a fair valuation.

M. O.—A lady, of course. —Place your sitter near the window, but *not* in front of it, and a little shaded by the wall, say about a foot back from the edge of the window. Hang a table-cloth over a tall clothes-horse, on the side opposite to the window, to reflect some light on the shaded side of your sitter, and do not let it encroach on the "field of view" of your camera.

ENQUIRING OPERATOR.—If your collodion is not thickened from evaporation of the solvents (alcohol and ether), add to it about ten minims of chloroform to each ounce; the pyroxyline will be precipitated in the form of drops of transparent jelly, but will redissolve on being shaken, and the collodion, though still thick, will flow very readily. This kind is preferable for dry plates. If the thickening be from evaporation the remedy is obvious: add ether.

S. W. L.—1. We never met with the effects this correspondent describes, and can only advise the use of Newman's or Mansion's colours, or the varnish sold for alabastrine pictures, to which they very readily and firmly adhere, too firmly if you are not careful. —2. Water-colours are quite unfit for glass positives, and a thick coat of body colour on the background is sure to produce the effect described. This was shown in Mr. Wall's "instructions."

JOHNSON WOOD.—You must be a *very* new subscriber, as if you read our *last two* numbers carefully you will find most of your queries answered in reply to other correspondents. Before development it is only necessary just to wet the whole surface, in order to allow the developer to float readily. You have too little acetic acid in your developer; use at least twice the quantity named. No wonder it turns muddy soon, your exposure is too long; try half the time. For preparation of plates, see our last.

H. COOKSEY.—There is no good method of converting positives into negatives. The two most promising are, producing a deposit by bichloride of mercury, and then blackening by ammonia (as introduced by Archer); and next, the conversion of the silver into an iodide, by a weak solution of iodine (a few drops of the tincture added to some water), washing, covering with nitrate of silver, expose to light, and then redevelop. Another course has been recommended, but we fear with but poor results, namely, whiten with the bichloride of mercury, wash, and turn the deposit *yellow* by iodide of potassium.

C. F. D.—1. The specimen is not good enough to enable a fair judgment of the lens to be arrived at.—2. The negative is very much under-exposed; it would have borne at least double the time you gave with the materials used. We notice crapy lines in the collodion, the slate roof is a mere white patch, and the foliage dabs of black, with white-washed paths in the garden—all indicative of under-exposure and over-development.—3. Fothergill's process is excellent for printing transparencies. The time of exposure to gas-light must depend upon distance from the light, density of the negative, and sensitiveness of plate. It would be impossible for us to guide you with certainty until you are more skilled than you yet appear to be.—4. We have given all that has been published with regard to Mr. Petschler's process, but you may safely use half albumen and half water.

BYNX. — 1. We have already given all that is published respecting Mr. Petschler's method of working the collodio-albumen process, but to any one who is familiar with the Fothergill process the details ought not to present any difficulty. The processes are precisely the same up to the coating with albumen, the only difference being that in Petschler's the latter contains about two grains of chloride of ammonium to each ounce of fluid, and we have reason to think that equal parts of albumen and water are sufficient for the purpose. After coating with albumen the plates are to be drained and *thoroughly* dried by aid of heat. Before exposure they are to be rendered sensitive by *copious washing with ordinary water*, and again dried—this time, of course, in the dark. Develop as in Fothergill's process. 2. We know of no work equal to Hardwich's *Manual*; but the best toning formulæ have all appeared repeatedly in this Journal. 3. The fault lies with your bookseller; if you send a subscription by post-office order to HENRY GREENWOOD, *Publisher*, 32, *Castle Street, Liverpool*, you can have it delivered by post on the days of publication, and sending it abroad is merely a question of postage. Write to the publisher.

☞ *All* EDITORIAL *Communications*, BOOKS FOR REVIEW, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 126, Vol. VII.—SEPTEMBER 15, 1860.

Our worthy friend, the editor of the official organ of the Photographic Society, has, in the last number of that publication, directed attention to the subject of the sale of photographic copies of works of art by the authorities of the Department of Science and Art at the South Kensington Museum, at the same time recording a strong protest against what is regarded as an unfair interference with private enterprise in reference to the commercial aspect of the question.

We have no great affection for South Kensington and its *Department of Science and Art*, which we consider to have been established and maintained upon the most barefaced of false pretences—that of offering facilities for popular instruction in Science and Art—while it is located in such a position that the majority of *the people*, for whom it is ostensibly designed, cannot approach it without the expenditure of money (and time, which is money's-worth) that they can very ill afford. Moreover, in making South Kensington the head-quarters for preserving the Turner and Vernon collections of pictures a direct breach of faith is committed with the Nation, which has decided, through its representatives in parliament, that its national collections shall *not* be carried there. But, who knows? perhaps this is merely a temporary arrangement *for the convenience of photographing each picture.*

When the Photographic Society and its annual collection were "taken in" there, we strenuously opposed the proceeding, and predicted what actually occurred — that *the people* would not go to see it. They did not; and although the Society was charged no rent it was out of pocket, and the affair proved a dead failure.

Having no love for the "Department" we are not over-inclined to argue in its defence in the smallest degree; but, nevertheless, we must "break a lance" with our worthy friend in consequence of a few passages which we find in the article to which we have adverted, *e.g.*:—

"We have examined Mr. Scott's evidence, in which he stated that the operations of the Department in Science and Art had had the effect of *entirely destroying photography in its higher branches as a profession.*" Again:—

"*He had* been authorised by Mr. Roger Fenton, &c., to say that since, &c., he *had given up* all the higher branches *of photography.*"

Poor Fenton! To think that he should come down to be but a second-rate photographer! by his own admission, too! We must have one more extract, but this time from our friend's article—*not* from the abstract of evidence; and here it is:—

"We need not point out to our readers that with such an oppression as that it is impossible for *the higher branches* of photography to thrive; and if this system be permitted *the knell of photography is sounded.*"

It is perfectly evident from the context that the phrase, "*the higher branches*" of photography, as here used, is intended to apply to the *mere copying* of paintings, *et hoc genus omne;* and this appears in the official organ of the Photographic Society in its most official manner! If we are not egregiously mistaken, we apprehend that there are but very few of our readers, or of those of the Society's Journal, who will concur in this view of the case. That the copying of works of art may be, and undoubtedly is, a very useful application of photography, we are ready to admit; but that it has the smallest claim to rank as one of the higher branches we most strenuously deny. And whatever may be the claim of certain professional gentlemen who gain a livelihood by copying paintings, &c., photographically, to have their cause against the Department of Science and Art advocated, we have not the slightest fear that, even if the whole copying practice were utterly annihilated, the *knell of photography* would have been sounded, or that the scientific and art portion would suffer in any material degree. Our good brother editor has allowed his kindness of disposition to blind his judgment; and in his enthusiastic attempts to advocate the cause of his injured friends he has fallen into the common error of trying to prove too much, and has thus got himself into a scrape. Only fancy reproduction being classed as one of the higher branches of photography! Printing, then, we presume, belongs to the *higher branches* of authorship. We will conclude by the old saying, "save us from our friends!"

The recent experiments of Messrs. Petschler and Mann, relative to the preparation of collodio-albumen plates, appear to have excited considerable interest amongst our amateur brethren of the camera, if we may judge from the numerous remarks made in reference thereto by our correspondents. This is, of course, no more than we anticipated would be the case, from the practical value of the discovery which these gentlemen have made and published; and, as everything in connexion with it is worthy of consideration, we beg the attention of our readers to a communication, which will be found in another column, from Dr. Hill Norris, of Birmingham, which bears upon the subject. We are, however, scarcely prepared to accept the theory advanced, that the impression effected by the agency of light is merely (in all cases) an "electrical" one, as there are many facts which appear to be totally opposed to a corroboration of this view.

That the action of an alkaline chloride in removing the actinic impression is very energetic we readily admit; but we perceive no greater discrepancy in the assumption of a removal of the latent impression (even though it be the result of decomposition), by means of the subsequent decomposition of the chloride, than by supposing it to be due to the release from an electrical condition of the film. That an electrical action may, and most probably does, accompany the actinic impression we see no reason to doubt; on the contrary, there is every reason to anticipate its existence. But is not this rather the effect than the cause of the action? It is highly probable, also, that the electrical force may have much to do with the development of the image, and this especially in the daguerreotype plate. We

cannot but think, however, that there is more than this in all cases where any modification of the Taupenôt process is employed, in which the albumen plays so very important a part. Moreover, the layer of iodide of silver may be entirely removed from a collodio-albumen plate, subsequently to its exposure in the camera, and prior to development of the picture, as demonstrated by Mr. Young, of Manchester. Surely, the action of the hyposulphite of soda, and the subsequent copious washing in water, would be sufficient to remove any trace of a purely *electrical* image. We are, therefore, inclined to conclude that a perfectly satisfactory solution of the principle involved has yet to be discovered.

Before concluding our remarks upon this point, we may as well record the fact, that plates prepared with collodion and albumen—the latter containing a decided excess of citrate of soda—are sensitive to the actinic action. Of this there is no doubt, as the following facts will demonstrate:—Being about to take a short holiday we hastily prepared a dozen dry plates, by the Fothergill process, as indicated in a recent number of this Journal, employing dilute albumen for the purpose, containing two grains of citrate of soda in each ounce of the dilute solution. Being several times interrupted during the preparation of these plates, we put down two of them to drain, after their having been coated with the dilute albumen solution; and, having been called away at the time, we accidently placed them to dry on returning to them, without having previously washed off the superfluous albumen, as ought to have been done. This fact we remembered the next morning, when proceeding to store away the plates in a tin box; but, not having placed them in any regular order in the drying rack, we were unable to discover which two had been treated as described.

As there was no help for the omission, we simply made up our mind to find two out of our stock of plates turn out failures; but the provoking part of the business was, that we could not calculate upon *which* two they would be. After our return to town, we developed the several pictures, and the pair of culprits were unmistakeably discovered: an image was rapidly produced upon both of them, with sufficient detail to distinguish the exact localities of exposure, but as rapidly the whole plate in each case became enveloped in a dense fog, which, though utterly destroying the negatives for any practical purpose, by no means entirely obliterated the impression. As these were the only two plates, out of the dozen taken, that behaved in this manner, we have no reasonable doubt that they were any others than the two which we were aware of having imperfectly prepared. It is not improbable, therefore, that had we known which of them were in this condition before development, we might possibly have obtained upon them presentable pictures, by very copious washing, so as to remove the excess of citrate, prior to pouring on the developing solution, instead of merely moistening them, in order to allow the developer to flow without interruption; for it is an incontestible fact that the impression was there in spite of the excess of the alkaline citrate salt.

We have experienced both surprise and regret on finding that our Manchester friends have spoken of our notice of M. Petschler's recent discovery, connected with the collodio-albumen process, as being unfair, or, what amounts to the same thing, that we have not quite fairly put the matter of that gentleman's important discovery before the public. The particulars of the charge against us will be found in the "Report" of the last meeting of the Manchester Photographic Society, which we publish this day, and which are contained in the remarks of Mr. Mabley and Mr. Sidebotham. We should have felt really at a loss to have conjectured in what manner we could possibly have given offence but for Mr. Mabley's assertion that we had attempted to detract from M. Petschler's merit by insinuating that his discovery was only a variation of the Fothergill process. Such a notion on his part can only have arisen from entirely misunderstanding our observations. We had not the most remote idea of making any insinuation, or of detracting from merit that we were delighted to acknowledge; and this, we think, will be sufficiently manifest to any one who will turn to pages 231 and 248 of the current volume, and re-peruse what we have written on the subject. In the latter place cited we pointed out the analogy of *principle* involved in the preparation of collodio-albumenised plates by the formula of Messrs. Petschler and Mann, as compared with those by the modification of the Fothergill process, which we are in the habit of employing—this analogy being revealed by Mr. Petschler's discovery. We cannot perceive in what way this indication detracts from the merit of the *discoverer of the principle*. In our opinion it rather tends to its exaltation. At any rate, we can assure our Manchester friends that we hold Mr. Petschler's discovery in quite as high esteem, both as regards utility and novelty, as the most enthusiastic amongst them. We trust that there is no room for misunderstanding this assertion.

PHOTOGRAPHIC CONTRIBUTIONS TO ART.

If anything had been wanting to convince us that the mere copying of paintings, drawings, or engravings by photographic agency did *not* constitute "the highest branch of our art" (an error into which, we must admit, there was but small chance of our falling), it would certainly have been supplied in three little studies by our indefatigable friend, Rejlander, of Wolverhampton, which have recently come to hand. As our friend is an artist in the widest acceptation of the term, of course it will happen that even in such a "mechanical" art (according to those who fear its power) as that of photography, a bit of true feeling or humour, as the case may be, will peep out; and our perversity is so incorrigible that we will persist in estimating these productions at a higher rate as *photographs* than the very best copies of the finest pictures in existence, and that simply because we fancy there is more brain work employed in the photographic part of the composition. Be that as it may, the three specimens before us have each a thought included in its structure which fits it either to "point a moral or adorn a tale."

"Coming Events Cast their Shadows Before,"—though but a trifle in itself, besides exhibiting its touch of humour, is very artistically conceived and executed, with which, even regarding it merely as a portrait, the individual represented could not possibly fail to be perfectly satisfied. A young man, reclining in an easy chair, with his meerschaum in the left hand, is with the right caressing with complacency a very incipient *moustache*. The gratified expression, the general ease of the attitude, the harmonious combination of the lines of the accessories, viz., the chair, drapery, &c., combined with the admirably graduated and suggestive background and delicate half-tints of the shaded portions of the face and figure, call forth the emphatic expression of approbation in the spectator.

"Have a Tune, Miss?"—is enough to throw Mr. Babbage into a paroxysm of indignation, as it is difficult to avoid being convinced that one of his inveterate persecutors, an itinerant piano-grinder, is not in reality before him. In this, the manipulation of the photograph is particularly to be admired as well as the composition; for, not only is it brilliant, but it is entirely free from spottiness, and, what is very rarely noticeable in a brilliant picture, is destitute of any absolutely white parts,—being round, soft, and delicate throughout.

But, if these two elicit admiration, what shall we say of "The Disciple?"—Indeed, there is very little to be *said* about it; but we *think* the more. As a piece of fine statuary, it appeals direct to the imagination, insinuating an idea, that is, nevertheless, almost inexpressible in words. As we gaze, we do not heed whether it is a drawing, or sculpture, or a photograph, or what not, that we are looking at, and are intent only on comprehending all the meaning involved in the composition.

We had almost forgotten to intimate, that it is simply the classical-looking figure of a youth, in an attitude of wrapt attention, that forms the subject. Is it not St. John, the beloved disciple?

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 12.

In the July number of the Photographic Society's Journal appeared a letter from Mr. Maxwell Lyte, offering a formula to the collodion committee. Although it is our intention to differ from Mr. Lyte on this particular occasion, we do so in the best possible spirit; for we have often availed ourselves of information derived from his researches, and have admired his perseverance in continuing the pursuit of photography long after its novelty has ceased.

The proposal to employ *paper manufactured from linen* as a material for pyroxyline will doubtless meet with support from many, since there is an ease and comfort in working with linen, which prepossesses strongly in its favour, and the collodion has many very desirable properties, such as fluidity, adhesiveness, and a capability of remaining for a long time in a moist state. It was not, therefore, without reasons which appeared very cogent, that in offering a formula for a normal collodion we were induced to discard the fibre of linen, and to employ that of cotton in preference. Stability, previous to iodising, is a point of the first importance in a commercial collodion, liable at any time to be sent to the colonies or other distant parts; and, according to our experience, the most stable plain collodion cannot be made out of linen.

Let us examine the above statement, that linen is not suitable for making the most stable collodion! What are the grounds for such an assertion? First, we say that experience proves as much: the collodion decomposes more rapidly, both before and after iodising, than collodion from cotton. "But," Mr. Lyte will reply, "perhaps you did not properly adjust the temperature, or the proportions of the two acids, or the amount of water, all of which must be different when linen is used instead of cotton." We say, however, that even after allowing for the peculiarity of the fibre with which we had to deal, and *humouring* it, so to speak, in every possible way, we could not succeed in preparing the most stable description of collodion out of linen. Placing Mr. Lyte once more on his defence, we can imagine him to continue it as follows:—"Stability is not by any means lost sight of in the proposed formula. You will see that a portion of bromide is introduced, which adds to the keeping qualities, and the unstable iodide of ammonium is superseded by the iodide of sodium." We allow all this to be good, and in the right direction; but so much having been done, why not do more, and employ the most stable form of collodion, as well as the most stable iodiser? This is the point upon which we join issue with Mr. Lyte; and although he avoids all mention of the subject in his letter, we see that, for some reason or other not explained, he is indisposed to adopt the views which we lately brought forward on the subject of pyroxyline. Many still think that too much has been said about photographic pyroxyline; but we entirely differ from them, and believe, as we have often before affirmed, that it is the very keystone of the collodion process.

It may be asked, what can be given as a sufficient reason why the bleached fibre of flax should produce a pyroxyline of less stability than that derived from cotton? We reply, that although chemistry has not at present clearly defined the two forms of cellulose above alluded to, we are convinced that there are important differences between them. Whether it be in consequence of the bleaching processes through which the flax passes, we know not, but our experiments have always shown that linen is more readily affected both by acids and alkalies than cotton or calico. You may select linen and calico of precisely the same fineness of quality, and yet the former will dissolve in a nitrosulphuric acid mixture, in which the latter will not dissolve. The linen also appears more prone to pass into the state of *sugar*, and from thence to nitro-glucose, than the cotton fibre. When, therefore, we examine nitro-glucose and prove it to be an unstable substance, producing great intensity of collodion, we are not surprised to find that the collodion from linen partakes more or less of the same character.

But supposing we allow, for argument sake, that linen is a desirable substance to employ, would it not be better to use it *as linen* than to purchase a paper made out of linen rags. We have no security whatever that the manufacturer will use any one description of rags for his paper: they will be new or old, as he finds most convenient; and it has been shown that both cotton and linen undergo a change by continual use, which is detected on making the fibre into pyroxyline. Mr. Heisch has lately stated that Swedish paper may be depended upon, but we are quite sure that the contrary is the case. In speaking of the purity of Swedish paper, chemists probably refer to its use in the laboratory, and to its freedom from ash after burning. The photographer, however, cares nothing for the inorganic salts which produce the ash, because they are dissolved out by the nitro-sulphuric acid. It is of far more importance to him that the paper should always be made from the same description of cellulose, and this is not the case with the Swedish paper. At one time, when we were in the habit of preparing collodion largely from Swedish paper, we received a supply which proved to be entirely different from that which preceded it, although the characteristic water-mark was upon it. The old sample had produced pyroxyline which gave a fluid collodion with seven grains in the ounce of solvents, but this one admitted only of the solution of five grains, and even then the collodion proved rather ropy and non-adhesive. Without any doubt the objectionable sample (of which the importer had a stock of forty reams) contained *cotton* in its composition, and no chemist, however eminent, shall persuade us to the contrary. Nevertheless we admit that Swedish paper is more to be depended on than other paper in the market, and that in the majority of cases it will be found to produce the limpid quality of collodion.

With reference to the use of iodide of sodium as an iodiser, in place of iodide of potassium, we see but one objection to it, viz., the difficulty of obtaining iodide of sodium commercially in a pure state. Some time since we ordered half-a-pound of this iodide from a firm who have a reputation for pure chemicals, but it did not prove equal to the best iodide of potassium in sensitiveness. The difference was not great, and in bromo-iodised collodion almost inappreciable; but it became very evident when the collodion was iodised simply, without any admixture of bromide. The preparation of iodide of potassium is now brought to such perfection, in consequence of the great demand for it, that it would be difficult to supersede it by any other iodide, unless a marked advantage could be shown. The iodide of cadmium has, it is true, been successfully introduced into commerce, but then it must be allowed that the advantages which this iodide offers are very remarkable. No possible reason can be adduced why iodide of sodium should not be made of equal purity with iodide of potassium, if the operative chemists would take the matter up; but how are they to be persuaded to do so? In no other way than by an extensive and continual demand for iodide of sodium on the part of the consumer, and to ensure this demand it will be necessary to convince him of its superiority. Compared with iodide of potassium iodide of sodium is more soluble in strong alcohol, and hence less liable to crystallise in the collodion, whilst nitrate of soda, the product of its action on the bath, is far more soluble in water than nitrate of potash.

In summing up what we have to say of Mr. Lyte's formula, we should consider it as likely to satisfy the wants of the amateur who prepares his own collodion, in small quantities, as he requires. But as regards the commercial manufacturer who supplies *a simply iodised collodion free from bromide*, we advise him to use cotton, and not paper, for his pyroxyline; otherwise he will probably have to undergo an uncomfortable experience in the form of letters from dissatisfied purchasers, who, having laid in a stock of the plain collodion, find at the expiration of some months that it has greatly deteriorated in quality.

OBSERVATIONS ON ALBUMENISED PAPER AND ALKALINE GOLD TONING.

By C. Jabez Hughes.

No. I.

As the verdict of the photographic world may fairly be considered to be given in favour of albumenised paper as the best known material for printing upon, any investigation tending to improve its production may be considered of value, particularly as for some time past very many complaints have been made of its quality. The *odium photographicum*, deservedly attached to the old acid hypo. bath, seems likely to be transferred to this unfortunate material, for certainly so great an outcry has never been raised against it as at the present time. This is so eminently the case, that many practical photographers declare that at no former period was so much bad albumenised paper extant as during the present season. To this opinion I cannot subscribe. Whilst freely admitting that much, very much, of the paper in the market appears to be produced *only to sell*, and certainly merits all the condemnation it has received, yet there are other causes in operation this season to which may be attributed many of the printing vexations, besides the ignorance and carelessness of the preparers of albumenised paper. Foremost among these causes stands the altered method of toning that is getting into general use. I believe the great bulk of photo-

graphers are now convinced that toning and fixing by one operation in a gold and hypo. bath is as unsafe in practice as it is indefensible in theory. With this conviction some modification of the alkaline gold toning (I wish we had a better term) has been adopted, and speedily new difficulties have arisen, and which have hastily been attributed to faults in the albumenised paper. It is certain that many papers that work very satisfactorily with the old gold and hypo. bath give no end of trouble with the alkaline gold. The latter method, despite its great merits, certainly requires peculiar kinds of paper and more careful albumenising to ensure the highest order of prints. When it is remembered that the chemical reactions are different in the two toning processes, it cannot be surprising that the results should vary; and if these results, though much better in some respects, be more difficult in others, it is a duty to investigate these difficulties with a view to their removal.

In the foregoing remarks I have assumed that the main complaints have arisen from the troubles experienced in reducing to practice the superior method of toning, by using paper not adapted for the process. That there are other causes of complaint I have no doubt, and will allude to them in the course of these articles; and if I should be so fortunate as to elicit during the course of the discussion the experience of some other practical photographers who have paid attention to this subject, great good must result. The subject is one much needing investigation, and is at the present moment thrust upon us by the daily complaints we hear.

The term "bad albumenised paper" is so vague, and the causes of badness so various, it is difficult to know what is meant by it. It is much easier to know what constitutes good albumenised paper. Though there never was or will be any paper that will please everybody, yet certain qualities are universally acknowledged as being essential to well prepared albumenised paper. The paper itself must be free from holes and metal spots, and sufficiently strong to bear handling freely during washing. The surface must have a uniform glaze, without any marks of air-bubbles, irregular streaks, patches, or drainings in the layer of albumen. It must not have finger marks on it, or be creased. It must be albumenised on its right side, for all papers have a right and wrong side. The gloss must be perfect up to the edge and in the corners. During the process of hot-pressing, and afterwards when lying in the ream, no foreign substance must be allowed to get between the sheets, such as pins, bits of string, scraps of newspaper, &c. I have seen the impression of a pin sent through twenty sheets, and annoyingly present in the finished pictures.

Good albumenised paper, after it has been sensitised, should retain its whiteness in hot weather for twelve hours, and in cold weather for twenty-four hours or more, without discolouring. It should tone uniformly without showing any patches or streaky lines, that obstinately refuse to change colour. It should not have the appearance, after toning, of being freckled all over with little red spots; neither should it have a mealy, granular, grey look, especially in the deep shadows.

If the toning is properly conducted—and of this more hereafter—the paper should change to a rich colour in from two to five minutes in the alkaline gold, and from five minutes to a quarter of an hour in a gold and hypo. bath. When toned, fixed, washed, and dried, the *whites* should be really white, and have no yellow tinge; and the paper should retain sufficient of its sizing to prevent the adhesive material from penetrating to the face when the picture is mounted. Any paper possessing the above qualities may certainly be considered "good albumenised paper," and in the proportion that it varies from the above high standard it may so far be designated bad.

In order to properly examine these conditions of excellence, the subject must be divided into three parts, namely:—The Plain Paper—the Operation of Albumenising—and the Toning Process.

The plain paper.—When it is considered that the picture on an albumenised print is very superficial and mainly in the albumen, it might reasonably be supposed that the paper played a very unimportant part, serving little else than as a convenient substratum for supporting the albumen, just as the glass plate does the collodion film. However feasible this view may appear it certainly is not correct, for the nature of the paper is of the greatest consequence: the film of albumen serves to give an artificial hardness, and otherwise modifies the result, but the main character of the finished picture depends on the paper itself. Thus, if a paper is rough and coarse, the albumen will not conceal that roughness, but it will show itself through the glaze, no matter how highly it may be albumenised and hot-pressed. Some papers have a tendency to give red, others blueish or black-toned prints; and the layer of albumen, as well as the chloride it contains, will at best only modify, but never remove, the original tendencies of the paper. I do not say that a paper is bad because it has a rough surface: for certain subjects it is a great merit. Artists have a great craving for this sort of paper; but if one has a rough-surfaced paper it must not be expected that albumenising will make it a smooth-faced one, or that the roughness is indicative of any fault in the albumenising operation. Not only will the roughness or smoothness of surface, but also the raw material of which the paper is composed, the sizing, the bleaching agent, the thickness or thinness of the sheet, and even the molecular arrangement of the fibres, affect the nature of the photographic print. Though these modifying influences are well known to persons in the habit of preparing paper, yet the bulk of the photographic public who purchase paper ready to their hands are not aware of the extent to which their pictures are affected by these agencies. They think that albumenised paper is simply albumenised paper all the world over, and that the terms positive and negative, French and German, Rive and Saxe, are mere refinements about which they need not bother their heads; all they want is a highly-glazed paper, upon which they can print and tone without any trouble, and if they do not get this the fault lies with the person who undertakes to albumenise the paper. This idea I wish to dissipate. I desire to show that the resources of the albumeniser are limited. That the public must meet him half-way, and select those papers they find best adapted to the toning processes they wish to practise, and not take any paper indiscriminately. The interests of the albumeniser and the photographer are the same; and it is not to be supposed that the former will go on continuously producing paper that he knows is not suited to the wants of his customers. Vague and general complaints are not enough: the faults must be clearly defined, and without doubt they can be amended. As a rule, it is certain that photographers cannot prepare their own paper, neither can albumenisers try their papers upon the same wholesale scale that their customers do; therefore, unless there is a harmony between them, the paper will not be produced to suit the new order of things, and photographers will either be continually making complaints, or fall back on the old hypo. baths as the readiest means of extricating themselves from their troubles. Far be it from me to say one word against legitimate complaints, or to lift my pen in justification of streaks, dirt, air-bubbles, creases, or similar faults. These are obviously the result of carelessness or ignorance: yet photographers should be impressed with the fact that all papers have their distinctive peculiarities, which can never be avoided; that some are better suited for one process than another; and that a given sample, if free from the above defects, is not necessarily a "bad albumenised paper" because Mr. A. B. cannot get prints to his taste with it. It will be my endeavour to point out some of these peculiarities, and, where faults are acknowledged, to suggest remedies.

Nearly all makers have two varieties of paper, thick and thin. In calotype days these had names given them, which they have retained ever since. These photographic pioneers—for they may be spoken of almost as a race that has died out—found that the thin paper was finer in its texture and better adapted for negatives, hence they called it *Negative* paper; whilst upon the thicker kind the best prints were produced, so that was called *Positive*. The names are retained to this day, though both are now used for printing upon. Negative paper is not only thinner, but generally finer in its substance. It seems to have a closer grained surface, and is well adapted for prints where great sharpness and detail is required. This paper has therefore been in great use for stereoscopic work. But it requires careful handling in the washing, for it is very tender, or it will break with its own weight when in the water. The thicker kind, or positive, though the surface is not so fine, has other counterbalancing advantages: it gives more vigorous prints, and is altogether better adapted for larger subjects, not only by the greater boldness of image, but by bearing a rougher handling in the water. With English, French, and German paper these peculiarities of the negative and positive kinds will hold good. It will be obvious, from the above remarks, that each of the two papers has its special advantages and disadvantages, and it is for the photographer to select according to his requirements.

The papers generally used are English, French, and German. Each has its own character. Belgian papers are also in use, but the makers imitate either the French or German; and in proportion as they approach either, so are they generally classified. English papers are not now much in general use. During the pre-Collodion period, however, they were in great repute. Old calotypists used to gloat over their reams of Turner and Whatman; for, like some

other good things, the paper was held to be better the older it was. Musty old-fashioned stationers' shops in back streets, out-of the-way neighbourhoods, and distant villages used to be explored, and the dustiest and darkest corners hunted out to discover some forgotten ream from the famous Chafford Mills. Continental calotypists (there were no *photographers* in those days) took their stand on "Papier Anglais;" but all this has passed away, and with it the reputation of English paper. With Collodion came in Rive, and Canson, and Saxe. The English paper was not found adapted for the new era:—it would not tone; would give red foxy pictures; was coarse on the face; was sized with gelatine; was of awkward size; and would not cut up profitably. Thus, with some show of reason, English paper got elbowed out; but we cannot doubt, when the paper duty is removed, the same improvements will occur that took place in the glass trade, and that many patriotic paper makers will volunteer, in self-"defence, not defiance," to stop the invasion of the French—paper.

The fact is certain that the bulk of the paper we photographically consume is imported. The reason why we are so dependent will, in some degree, be made apparent in the next article, when we discuss in detail the peculiarities of English, French, and German paper.

ON FIXING POSITIVE PROOFS.

By MM. Davanne and Girard.

We have shown by our preceding studies that, among the various fixing agents which may be employed in photography, the best is hyposulphite of soda. We cannot, however, assert that it is absolutely good; for in our last essay we enumerated various causes which may bring about its decomposition, and consequently destroy the proofs.

These causes of decomposition are:—

1. The action of light, solar or diffused.
2. The presence of nitric acid in the printed proof.
3. The total saturation of the hyposulphite of soda by the salts of silver.
4. The local or accidental saturation resulting from interposed bubbles of air, from the proofs sticking together, from being partially immersed, and from the solution of hypo. being too weak.
5. The presence of free sulphur or thionic compounds, caused by anterior decomposition.
6. The voluntary or accidental addition of any acid.

Therefore, in practice, we must protect ourselves as much as possible from these causes of alteration; and we shall now examine the rational conditions of good fixing from the moment of taking the print out of the printing-frame, and of observing that, hitherto, we have only considered the subject of toning.

I. *Modifications to which the proof must be submitted before fixing.*—Our first care must be to remove the black solarised margins from the proofs, or, what is better, avoid them by covering up the margins of the sensitised paper in the printing-frame with a border of black or yellow paper to admit the negative. We thus prevent the solarised margins from acting upon the successive baths wastefully, especially on the toning-bath, which they influence more than all the rest of the proof.

The positive proof, on removal from the printing-frame, contains, on the one hand, chloride of silver, metallic silver, and a combination of silver with organic matter: these three compounds are insoluble, and have no direct action upon the hyposulphite of soda. On the other hand, it contains nitrate of silver and free nitric acid, the action of which on the hypo. is immediate: it is easy to remove these two latter bodies, or render them inoffensive. It is sufficient to wash the proofs first in plain water, and then in a bath composed of

Bicarbonate of soda	1 part.
Chloride of sodium	5 parts.
Water	100 parts.

The reaction upon the soluble compounds takes place immediately the nitrate of silver is transformed into chloride of silver, and the nitric acid into nitrate of soda. We may employ simply a solution of bicarbonate of soda in water; then the nitrate of silver will be transformed into the insoluble carbonate, and the nitric acid be neutralised as before, but especially if the preliminary washing be omitted. In that case we must increase the dose of the alkaline bicarbonate, which may act upon the sizing of the paper; therefore we prefer to employ it weak, with an excess of chloride of sodium.*

* *We have satisfied ourselves, by direct experiment, that if nitrate of silver be added to a mixture of chloride of sodium and bicarbonate of soda, the precipitate formed consists almost exclusively of chloride, and of a minimum proportion of carbonate of silver*

The employment of the preliminary washing in pure water will secure the same weight of hyposulphite of soda, fixing double the number of proofs; but if it be found that this washing complicates the operation, it may be omitted, and the proof be passed immediately into the solution of bicarbonate of soda and salt: the silver passing thus from the soluble into the insoluble state, will have no other injurious action on the hypo.-bath than that of saturating it more rapidly.

II. *Concentration of the bath of hyposulphite of soda.*—We know theoretically that the solution of hyposulphite of soda must be concentrated: it is necessary that it should act rapidly, and that the hyposulphite of silver be dissolved immediately it is formed in the substance of the paper. Our experiments were made upon solutions of 5, 10, 15, and 20 per cent.: this last strength appeared to give the best results, and we stopped at it, although there was nothing absolute in it; it is a medium strength, and may be diminished or augmented without any inconvenience. This solution is filtered into a dish large enough for the proof to float in it freely without touching the edges. The quantity of solution must be proportionate to the number of proofs: in any case they must float freely.

The fixing should be carried on in a room lighted by yellow glass windows, so that a very feeble diffused light falls upon the dish. The proof, on its removal from the solution of bicarbonate of soda, must be immediately immersed in the hypo.-bath, carefully avoiding the formation of air-bubbles, adherence to the sides of the dish, and every cause that will prevent the liquid from coming in contact with both sides of the proof.

We may put several proofs at a time into the fixing-bath, but it is preferable to put in as few as possible, to avoid local saturation of the hyposulphite of soda, and the colour of the proofs will be fresher. It will be better to put only two back to back; that will not prevent quick working, as each sheet remains but a short time in the bath.

III. *Time of fixing, and its influence.*—In every experiment we have made, we have found that, after an immersion of ten minutes in the solution of hyposulphite of soda, the proofs obtained in the ordinary way, even without previous washing in pure water, were completely fixed; it is, therefore, only in exceptional cases, as in employing excessively thick paper, of concentrated baths of soluble chloride, or of nitrate of silver, that we must consider how long it will be advisable to prolong the fixing, which, as observed by M. Le Gray, should be as brief as possible. Too prolonged a stay in the bath of hyposulphite of soda will have a twofold injurious effect on the proof: first, in destroying its vigour, by partially removing the half-tones; and, if it must be toned after fixing, will render this toning if not impossible at least very difficult, and not so good. If the impression be too vigorous it must not then be weakened by a prolonged immersion in the hyposulphite of soda, but some other means must be employed* after the fixing.

(*To be continued.*)

ON THE ACTION OF THE ACETO-NITRATE BATH IN THE COLLODIO-ALBUMEN PROCESS.

By John Parry.

[Read at a Meeting of the Manchester Photographic Society, September 5, 1860.]

Some time ago, on preparing a few plates for printing transparencies by the collodio-albumen process, I accidentally removed part of the collodion film in the washing, after having sensitised in the ordinary thirty-grain silver bath. As the damage was but slight I completed the preparation of the plate in the usual way, and exposed it; but on developing I was much surprised to find I had little or no impression on the part from which the collodion had been removed, although the other portion of the plate developed in the usual manner.

I named this fact to several of my friends at the time, but paid no further attention to it then. Since, I resolved to make a few trials on this subject; for it would appear from the above that the only use of the aceto-nitrate bath is to coagulate the albumen, and if so, what is the maximum strength required for that purpose? The bath I had in use at that time was about fifty grains to the ounce of water: I therefore took half an ounce of it and added four and a-half ounces of water, making it about five and a-half grains to the ounce. I dipped one of the usual albumenised plates half way into the fifty-grain bath, allowed it to remain the usual time, removed and washed that part only—first in a dish, and after-

* *The very weak solution of iodised cyanide of potassium, proposed by M. Humbert de Molard, yields excellent results. We can employ, also, a weak solution of cyanide of potassium, of hypochloride of lime, or a concentrated solution of chloride of sodium.*

wards under a tap, allowing it to drain a few minutes. I now dipped the other end of the plate into the five and a-half grain bath, washed as before, and allowed the plate to dry. Next morning I placed this plate in the pressure frame, under a good even negative, previously marking the end which had been dipped in the five and a-half-grain aceto-nitrate bath. In developing I was not a little surprised to find the end I had marked came out first, and continued to do so, far outstripping the other in development.

I began to think I must have made some mistake, and resolved to try it over again. I now prepared an entire new aceto-nitrate bath, six grains to the ounce of water, and proceeded as in the first instance, marking the plate previous to dipping in the two baths. The result was precisely as before. Since then I have tried it in a great number of ways, but always with the same result. In my hands the weak bath has a greater tendency to blister, and the picture is on the surface, and not in the body of the film. This is remarkable, as the first experiment proves the picture to be at least on the collodion side of the film, if not in the body of the collodion alone.

I noticed, also, in two of my experimental plates, that at the junction of the two solutions the plate was quite insensitive to light, as may be seen on No. 2 and 3 [plates here produced]. But I did not succeed in repeating that on trial. It would thus appear that a much weaker bath will answer the purpose better than the one generally used. What may be the best strength I have not yet satisfied myself with by experiment; but have now reduced the one I have in use to twenty grains the ounce, and think I may reduce it still more.

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING THE PHOTOGRAPHIC IMAGE.

Report of the Committee, consisting of Messrs. Maskelyne, Hadow, Hardwich, *and* Llewelyn.

(*Continued from page* 254.)

The usual sensitive surface contains, if it does not consist in, iodide of silver with an excess of nitrate. But there are processes in which the plate is studiously washed with water to remove the nitrate, whereby, though it is impaired in sensitiveness, it retains enough of that quality for the production of excellent results. Though this retention of a susceptibility to the invisible impression has been attributed to mechanical causes, such as the state of division of the iodide, the porosity of the film, &c., the following facts seem to favour a chemical explanation:—Pure pyroxyline united with pure iodide and nitrate of silver, from which the nitrate of silver has subsequently been removed, and the film dried, is not susceptible of quick development after exposure in the camera; a mere trace of albumen introduced before the removal of the soluble silver salt, however, prevents its entirely losing this susceptibility. Gelatine, certain forms of sugar, resins, and various other bodies widely differing from one another in point of chemical character, possess a similar property, though the precise regulation of the processes employing them can hardly be said to be as yet mastered by the photographist. The products of decomposition contained in "old collodions," and some of the fresh preparations of pyroxyline, in which secondary products are not studiously prevented from being formed, would seem to share this power with the classes of bodies referred to.

But a question of the utmost interest to the scientific inquirer is involved in the chemistry of the iodide of silver: first, in respect to its power of forming combinations with the nitrate of silver; and, secondly, as regards the probability of these combinations forming photographic compounds with the albumenous and other bodies alluded to.

That the excess of nitrate of silver which is necessary in the *first* preparation of all the sensitive films does not act the same part as that excess does in the case of the chloride in direct processes, will be evident at once, inasmuch as the iodide of silver does not undergo reduction in the manner that the chloride does. In searching, therefore, for an explanation of the necessity of free nitrate, the mind naturally dwells on the compounds shown by Schnauss* and A. Kremer† to be formed by the action of strong solution of nitrate of silver on the iodide. Although the production of these bodies in any quantity and in a state of chemical purity needs conditions not present on the photographic film, yet there seems little doubt that, as iodide of silver is dissolved by the nitrate, traces of these remarkable compounds can readily exist in the films containing these two ingredients. If so, the highly photographic character of the compound containing 2·8 per cent. of iodide of silver described by Kremer, and the fact of these bodies being decomposed with the separation of iodide of silver by the action of water, are facts of high interest to the photographic chemist, and seem to throw considerable light on the hitherto obscure processes in which iodide of silver is employed. These two facts, indeed, may be held to explain, very nearly, the character of the ordinary collodion process, but they do not explain the "preservative" processes in which the sensitiveness of the film is, within certain limits, retained by the introduction of albumen, gelatine, resin, sugars, or other organic substances, to the numbers of which experience is continually adding.

For the explanation of the action of these substances we must recur to the facts already cited in the case of gelatine when used as a size in the direct processes. Thus, too, a plate coated in the ordinary manner with albumen containing iodide of potassium dissolved, will be found, on being raised from out of the silver bath, not to be opaque, and coated with a dense deposit of iodide of silver, but to appear highly translucent and opalescent in its character, and that even though the iodide be introduced with a liberal hand. In fact, the albumen is present not merely as a mechanical vehicle for the sensitive materials, but can be proved to have combined with those materials, and to play no insignificant part in their photochemical transformation. That this is so may be at once shown by adding some albumen to a quantity of the ordinary "silver bath,"—say the white of one egg, diluted with 1½ ounce of water, added to 40 ounces of bath. The iodide of silver with which the bath was previously saturated will be found in it no more: it is now to be looked for in the gelatinous precipitate which the albumen has formed. The precipitate is in fact a chemical compound of albumen with nitrate of silver holding in combination the iodide. This is, as might be supposed from what has been said of the albuminate alone, a highly photographic compound. We have stated that a similar compound is formed by gelatino-nitrate of silver and iodide of silver. Citrate of silver, glycyrhizine, and many other bodies share with these substances, and the first two possess even in a far higher degree than they the property of carrying down in a combination—or, so to say, in solid solution—the iodide of silver, and forming with it highly photographic products.

EXPERIMENTS AND CONCLUSIONS ON BINOCULAR VISION.

By Professor William B. Rogers.

[Read before Section A, at the Oxford Meeting of the British Association for the Advancement of Science.]

The following experiments, intended to test the theory of the successive combination of corresponding points in stereoscopic vision, are I believe in part new, and are in part modified repetitions of experiments already described by Professor Wheatstone and Professor Dove.

1. Let two slightly inclined luminous lines, formed by narrow slits in a strip of black card board, be combined into a perspective line, either with or without a stereoscope. Looking at this for a few seconds, so as to induce the reverse ocular spectrum, and then directing the eyes towards the opposite wall of the apartment, a single spectrum will be observed having the attitude and relief of the original binocular resultant.

As a strong illumination of the lines is necessary to bring out the full effect, the card board should be held between the eyes and some brilliantly white surface, as the globe of a solar lamp or a strongly illuminated cloud, care being taken to prevent the entrance of extraneous light.

2. Using the same arrangement, let the luminous lines be regarded *in succession*, each by the corresponding eye, the other eye being shaded so that no direct binocular combination can be formed. On looking towards the wall it will be seen that *the two subjective images unite to form a single spectral line, having the same relief as if the lines had been directly combined* by simultaneous vision, either with or without a stereoscope.

While the perspective image continues distinctly visible, let either eye be closed, the other being still directed towards the wall. The image will intantly lose its relief, and take its position on the plane of the wall as an inclined line, corresponding to the subjective image in the eye that has remained open. When the subjective impressions have been sufficiently strong, it is easy to

alternate these effects, by projecting first the picture proper to the right eye, then that of the left, on the plane of the wall, with their respective contrary inclinations, and then looking with both eyes we see the resultant image start forth in its perspective attitude.

It is hardly necessary to say that, to obtain these effects satisfactorily, the lines should be very strongly illuminated, and the observer should have some practice in experiments on subjective vision. Under these conditions I have found the results to *be perfectly certain and uniform.*

In these experiments, according to the theory of Sir David Brewster, the resultant spectrum, instead of being a single line in a perspective position, ought to present the form of two lines inclined or crossing, situated in the plane of the wall without projection or relief. The conditions of the experiments are such as to exclude all opportunity of *a shifting of the image on the retina*, and such shifting is obviously essential to the successive combination of pairs of points required by the theory in the production of perspective effect.

In reference to the first experiment, it might perhaps be maintained that, as the perspectiveness of the original resultant on which the eyes were conveyed formed part of the direct perception in first combining the lines, it would be likely through association to be included also in the spectral or subjective perception. But this consideration, which at best appears to me of little weight, is entirely inapplicable to the conditions of the second experiment. For here the eyes are in the first place impressed *in succession* with their respective images, and are not allowed to see the resultant; and yet, when they are together directed to the wall, *the perception of the single perspective resultant is at once originated.*

3. Without resorting to these troublesome efforts of subjective vision, the following experiment furnishes, as I think, conclusive proof that pictures successively impressed on the respective eyes are sufficient for the stereoscopic effect.

Let an opaque screen be made to vibrate or revolve somewhat rapidly between the eyes and the twin pictures of a stereoscopic drawing, so as alternately to expose and cover each, while it completely excludes the simultaneous vision of any parts of the two. *The stereoscopic relief will be as apparent in these conditions as when the moving screen is withdrawn.* Here, at each moment, the actual impression in the one eye and the retained impression in the other form the elements of the perspective resultant perceived.

It seems clearly inferrable from these experiments that the perception of the resultant in its proper relief does not require that each pair of corresponding points should be combined by directing the optic axes to them pair by pair in succession, as has been maintained. Nor is it necessary for the singleness of the resultant perception that the images of corresponding points of the objects should fall on what are called corresponding points of the retinæ. The condition of single vision in such cases seems to be simply this, *that the pictures in the two eyes shall be such and so placed as to be identical with the pictures which the real object would form, if placed at a given distance, and in a given attitude before the eyes.*

4. I have of late frequently repeated Dove's experiments with instantaneous illumination, leading, as is well known, to similar conclusions. In these I have found it most convenient to use the momentary bright flash of the Leyden bottle, connected with the Ruhmkorff coil according to Grove's plan. With a powerful coil of Ritchie's construction, and a brass disc 8 inches in diameter, having the usual concentric striation, I am able, even with a single flash, to see the luminous line in perspective, and by a quick succession of flashes I can have it as steadily before me as if illuminated by the sun.

A twin-drawing, of a simple geometrical solid, placed in the stereoscope, and illuminated by the same means, appears single and in just relief in all cases where the flashes recur at short intervals, and very frequently presents the same appearance even with a single momentary light.

To be assured that the effect was not due to the *recollection* of a previous stereoscopic impression, I have caused slides to be introduced of which the form could not be thus anticipated, and still have had no difficulty in describing the perspective resultant as exhibited by the instantaneous illumination.

5. On the inability of the eyes to determine which retina is impressed.

Let a small disc of white paper be fastened on a slip of black pasteboard, of the size of a stereoscopic slide, and let this be so placed in the instrument as to bring the disc centrally in front of one of the glasses, *the person who is to view it being kept in ignorance of the position of the spot.* On looking into the instrument, he will think he sees it with both eyes equally, and, without resorting to the expedient of closing his eyes alternately, will be *entirely unable to determine whether the spot is before his right eye or his left eye.* The spot appears to be placed in the mesial or binocular direction, and in the same position as that of the resultant image of two such discs, presented severally to the two eyes.

It may be concluded from this that the mere retinal impression on either eye is unaccompanied by any conscious reference to the special surface impressed, and that the visual perception belongs to that part of the optical apparatus, near or within the brain, which belongs in common to both eyes.

This experiment is, moreover, interesting from its bearing on the *law of visible direction.* It shows that the sense of direction is just as truly normal to the central part of the retina that has received no light from the object as to the part of the other retina upon which the white spot has been actually painted by the rays. In truth, *it is normal to neither*, but is felt to be in the middle line, between the two—that is, in the binocular direction. This experiment, therefore, contradicts the law which assumes that the direction in which an object appears is always in the normal to the point of the retina impressed.

LIQUID FOR CLEANING GLASSES.

By W. Miers.

The following preparation will be found very efficient for cleaning glass plates, particularly those that have been employed for collodion positives with iron developers:—

Water	1 ounce.
Hydrochloric acid	2 drachms.
Iodine	A few grains.

Rub the plates over with a pad of cloth saturated with the liquid, using a circular motion, and polish as usual.

ON THE DRY PROCESSES.

By Hill Norris, M.D.

The following letter and paper, which we received a few days back, appear to contain matter of such general interest, especially in reference to the experiments of Messrs. Petschler and Mann, that, although the latter was read just three years since, finding it has not yet appeared in these columns, we have determined on now publishing both, having obtained the requisite permission.

My dear Sir,—I take the liberty of forwarding you for perusal an old communication of mine to the Society here in September, 1857. It has, I think, a direct bearing on the recent experiments with chlorides. I am inclined to think that the effect observed is wholly due to the very potent action exercised by chlorides in removing the *excitation* induced by light. I have long noticed that if exposed plates were wetted with *common water*, and *re-dried*, the image was in most instances obliterated, while no such effect occurred with *distilled water.* A plate that has been well washed, and then treated with chloride, will contain a great excess of chloride (alkaline), owing to the concentration induced by the drying. I have found that one-third of a grain of chloride of ammonium in an ounce of the preservative wlil prevent the development of the image, and I have been in the habit of attributing this action simply to the effect of the chloride in *removing the image* at the *moment* of being *re-wetted*, not to any opposition to the action of light. It is difficult to understand how acids and their vapours, chlorides, &c., can remove the latent image, if we look upon it (the image) as being the result of a true decomposition; but it is not difficult if we view it as only an "electrical excitation"—a view that is daily taking stronger hold of my mind, and which every new fact tends to prove.

It gives me much pleasure to see you urging the daguerreotype as an example of pure iodide and bromide of silver being sensitive. We could not possibly have a more convincing proof freer from sources of error.

I am, yours, &c., HILL NORRIS, M.D.

Birmingham, September 4, 1860.

As the subject of dry collodion is now so thoroughly on the *tapis*, and many erroneous views in regard to its chemistry are prevailing, it may not be amiss for us this evening to investigate a little this part of the subject. Perhaps the most important question we can draw attention to is that of the sensitiveness or non-sensitiveness of pure iodide of silver to the actinic force, and on the thorough elucidation of this hitherto debatable point depends the future of dry photography.

It has for years been my effort to produce an "actinic tablet" of pure iodide of silver capable of retaining its property of receiving

impressions for an indefinite period, and retaining intact the impressed surface without alteration. This I may say I have succeeded perfectly in doing, as my plates are not found to deteriorate after a period of twelve months. This keeping property is due solely to the very stable character of iodide of silver, uncontaminated by the nitrate of that metal, or other foreign salt. You are aware that I have long advocated the removal of all free nitrate by copious washing, and this not from any unfounded prejudice, but from direct experimental comparison between plates containing large and small proportions of this salt with others in which it was entirely absent; and these experiments, repeated under every variety of condition, have invariably decided against the use of free nitrate in *absolutely* dry processes.

We will endeavour this evening to establish the following propositions:—

1. Pure iodide of silver, although not capable of blackening in the solar ray, is nevertheless in its nature sensitive to the actinic force so far as the production of latent images is concerned.

2. Nitrate of silver does not, in *dry processes,* hasten this action, or give intensity, but is retardative and injurious.

3. That many substances have the power of destroying the actinic impression subsequent to production, and of preventing its formation.

At an early period of my experiments I noticed that, if a dry plate were exposed to light under a negative, and afterwards immersed in a solution of bi-chloride of mercury, the latent image was destroyed. The same plate being well freed by washing from this salt, and again exposed, yielded an excellent positive. Pursuing this clue I find that iodide of potassium, in fact all soluble iodides, nitrate of silver, all acids, including the pyrogallic, and many salts, possess this quality in an eminent degree. Hence the discordant opinions in regard to the impressibility of pure iodide of silver. To prove that iodide of silver *is* sensitive to light, I proceed as follows:—Taking a collodion plate, I wash away as nearly as possible all free nitrate, and then immerse in a bath of iodide of potassium to neutralise the remainder. I now wash it repeatedly with distilled boiling water to remove this salt, and on exposure find the picture is as quickly and readily obtained as if no iodide of potassium had been used. Again, I take a plate, expose, wash, pour over one half only a solution of iodide of potassium; and wash thoroughly and carefully, so as not to contaminate the other half of the plate with the potassium. On development the part treated with potassium remains clear and white, the remainder blackens. Now remove by washing all developing solution from the plate; expose again, and in its turn the part previously preserved will blacken under the action of the developer. The first experiment shows that pure iodide of silver IS SENSITIVE to light. The second shows that iodide of potassium is obnoxious to the actinic impression, preventing its production, and if applied after exposure restoring the plate again to its normal condition. This is perfectly analogous to the action of the bi-chloride of mercury, and bears a striking similarity to the restoration of the daguerreotype plate by the fumes of iodine. Again, how can we on any other hypothesis explain the facts presented in the collodio-albumen process. These plates may (save the last sensitising or the final neutralisation of the alkaline iodide) be entirely prepared in the light. During the first sensitising of the plate in the nitrate bath, and its subsequent washing, it must have evidently been influenced by the actinic force, *but it is at once restored to its normal condition by the application of the albumen containing the alkaline iodide.* It is a singular fact that our very developing agents, chiefly due to the acetic acid, possess this quality in a marked degree, and this is the case with pyrogallic acid, although not apparent in the ordinary wet process, owing to the development commencing *instantaneously;* but if a dry plate be properly exposed, half of it flooded over with pyrogallic solution containing no silver, and allowed to remain on a few minutes, on developing with fresh pyro, containing silver, the part on which the simple pyrogallic was first flooded will be found nearly obliterated, while the other will come up strong and intense. A very effective way of showing this experiment is by spotting a plate with the pyrogallic before adding the silver. I exhibit such a plate for your instruction. In the spotted parts you observe the picture is nearly obliterated. Nitrate of silver, when acid, has also this property of conducting off the image; therefore in all experiments instituted for ascertaining the influence of actinism on pure iodide of silver, these facts must be taken into account, and the developing agent, silver, must be presented to the iodide *simultaneously.* Whatever the peculiar latent image may be shown to be, one thing is evident, that causes, apparently trifling, are capable of the most magnitudinous results. In M. Davanne's theory of the reduction of a portion of the iodide of silver to the metallic state, as constituting the basic image, I do not concur. If this theory be correct a visible picture should at length, without development, by a still further reduction of the iodide be produced, or at least the attractive force for molecules of silver should increase in the ratio of the exposure, and in a definite direction. When *nitrate of silver* is present in a film of iodide I am aware the picture will become visible by exposure alone; but this is owing to the direct action of light:—firstly, in its capacity of producing a latent image, having the power of molecular attractions; and secondly, as a developer in reducing the nitrate, and so presenting the minute molecules of silver to the attracting image or force. Pure iodide of silver can never be blackened as chloride and nitrate can, but it is nevertheless capable of receiving latent impressions much more readily than these substances. M. Davanne's conclusions that iodide of silver is slightly blackened by the solar rays is founded on experiments to which I take exception, because he used, in connexion with the iodide coagulated albumen, or in other words, a compound of proto-oxide of silver and albumen, which itself would blacken by exposure.

The latent image on a dry collodionised plate of pure iodide of silver will not become visible by any amount of exposure, but is as recurring as the colour on a daguerreotype plate. For instance, if a plate be exposed under a negative, for a few seconds, the picture, on development, will be positive; for a few minutes, and it will be negative; and so the changes may be rung, proving it I think to be an electrical and not a chemical phenomenon. These changes on a dry plate are distinct and definite, exhibiting this principle much better than wet plates.

On this subject I have much more to say, but as time will not permit in this paper I will now hasten on to the consideration of the pyroxyline best suited for dry operations.

Solubility in pyroxyline lies within a small compass, and depends entirely on the strength of the nitric acid. Too strong, it will be insoluble, but very explosive. Too weak, and the cotton dissolves in the acids. Then, again, there are two kinds of pyroxyline—the contractile and the porous—and each of these is subdivisible into the fluid and the glutinous. Hence, to make myself understood, I will classify them as follows:—the fluid contractile comes from hot strong acids; the glutinous contractile from cooler or cold strong acids; the fluid porous from hot weak acids; the glutinous porous from cooler or cold weak acids. *Ergo*, an acid mixture which when used cool gives a glutinous contractile, will, when used hot, give a fluid contractile. An acid mixture, which when cool produces a glutinous porous, will, when hot, produce a fluid porous kind.

Let the line A B represent a portion of a thermometer, ranging from 80 to 170°.

	A	
Fluid contractile	170 160 150 140 130	Extreme peroxidation within the limits of solubility with close impaction of constituent atoms by the action of hot sulphuric acid.
Glutinous contractile	120 110 100 90 80	Same degree of peroxidation with loose state of constituent atoms, owing to the sulphuric acid being cooler.
	B	

It would therefore appear that contractility depends for existence on a strong nitric acid, just capable of giving a soluble compound, while a porous pyroxyline depends upon a weaker acid; or, in other words, contractility is extreme peroxidation within the limits of solubility. Porosity lies below this point in variable degrees, and in proportion to its distance so does the porosity increase, or the less peroxidised the cotton, the more porous.

The acid mixture is here to be considered as the strongest sample capable of giving a soluble product. From 80 to 120 the pyroxyline will be more or less glutinous, but above this point it will be tolerably fluid, increasing in this quality up to 160, above which point it will dissolve. It will be found that collodion prepared from any of the above specimens of pyroxyline will not develop in dry processes. Now add to the above acid mixture a portion of water and the changed conditions may be thus expressed:—

A

Fluid porous	170 160 150 140 130	Lower degree of peroxidation, with impaction of constituent atoms by the action of hot sulphuric acid.
Glutinous porous	120 110 100 90 80	Same degree of peroxidation with loose state of constituent atoms owing to the sulphuric acid.

B

If the acid mixture dissolves the cotton, on raising the temperature to 160°, it is too weak. Any of the pyroxyline of this last formula will develop, but of course the *fluid* porous is the one to be chosen, and the collodion may be made as follows :—

Rectified ether ....6 drachms.
Alcohol (absolute).................................2 „
Cotton (soluble)....................................6 to 8 grs.
Iodide (cadmium) ....6 grains.

It will be ready for use in about a week, but improves by longer keeping. The best preservative solution is made by dissolving 80 grains of gelatine in 20 ounces of distilled water, heating to the boiling point, and filtering while hot through two thicknesses of bibulous paper. It should then be carefully boiled down to half the quantity, stirring well with a glass rod. When cooled down a little it should be poured into a bottle containing 1½ ounces of alcohol, and the whole shaken up well together.

We will now proceed at once to the *modus operandi :*—

1st Operation.—To clean the plates, place them for a few hours in a strong solution of washing soda, and while in, rub the surfaces well with a pledget of rag. Wash well to free from the soda, and then dry upon cloths that have been washed without soap; finally polish with a piece of old silk or wash leather.

2nd Operation.—The coating with collodion and sensitising in the nitrate bath is conducted precisely as in the ordinary wet process; and as the collodion does not contain acetic naptha, camphor, or other foreign body, the usual negative silver bath may be employed without running the risk of spoiling for the wet process.

3rd Operation.—For washing away all free nitrate of silver from the plate, provide three flat dishes of porcelain or gutta percha, and fill with pure distilled water (not common or rain water). Take the plate from the bath and permit it to drain for two minutes, and then immerse in the first dish of distilled water. Proceed now to prepare a second plate in the nitrate bath, and when this is ready, transfer the former plate to the second dish of distilled water, and so on till the first plate has passed into the third dish. The first water must not be used more than three times, when its dish must be washed out and refilled, and placed for the third or last swilling. When the plate is removed from the first water, it should be slightly washed, back and front, with distilled water, kept in a jug for the purpose, so that as little nitrate of silver as possible may be conveyed into the second water. While the plates are soaking, a rocking motion should be given to the dishes occasionally. The plate having remained for about five minutes in the third water, should now be taken out, and the surface slightly swilled. It is now, after draining about a minute, ready for the fourth operation.

4th Operation.—*Coating with Gelatine.*—To do this successfully, the gelatine solution must be made very hot (no fear need be entertained of blackening from this cause). The gelatine solution may be readily heated by placing a bottle of it in a saucepan of boiling water. The capacity of the bottle must depend upon the size of the plates under preparation. It must be understood that the gelatine is not heated simply to liquify it, but because it penetrates better into the pores of the plate, and the plate being heated dries more readily and evenly. Now take up the slightly-drained plate, and pour on one end sufficient of the hot gelatine solution to cover the whole surface, and impart to the glass a degree of warmth, float backwards and forwards for two or three minutes, and pour off by the opposite end into the waste pan; reverse the plate and repeat this operation, with the exception that the solution this time may be saved for the first application to the next plate. The plate is now ready for the last operation, viz., that of drying. This may be done either spontaneously or by artificial heat; in either case the plate must be reared up, face outwards, on one corner, in a very clean place. If prepared at night, they may readily be dried by an ordinary brisk fire, at the distance of about two feet. When dry, they should be securely packed, and will keep indefinitely.

Exposure in the camera.—From 50 to 150 seconds in bright sunlight will generally be found sufficient, although some objects will require as much as four or five minutes under the same conditions, viz.: with a stereoscopic view lens of six inches focus, and a quarter-inch aperture; with a large lens, twenty-one inches focus, inch aperture, in good light, from one and a-half to two minutes; with three-eighths aperture, from eight to twenty minutes.

Development of the latent image.—Wet the plate by immersion in a flat dish of distilled water (common or rain water will not do), drain for one minute, and then pour over a sufficient quantity of the following developing solution :—

Pyrogallic acid.............. ....3 grains,
Distilled water ....2 ounces,
Glacial acetic acid ....1 drachm,

having previously mixed with each drachm required three drops of a forty-grain solution of nitrate of silver. If this mixture should go muddy, it must be thrown away, and the measure well cleaned with cyanide of potassium solution. For stereoscopic plates, about two drachms of pyrogallic solution will suffice, and to this quantity six drops of nitrate of silver solution must be added. This mixture should be poured on to the plate at the end farthest from the body; off again at the other end; and opposite part to the first. The plate must not be put on a levelling stand, but kept in constant motion; and, if any inequality is observed in the development, let the solution be transferred to the measure, and poured on repeatedly at that particular point till the development is equalised. When the action of this first dose appears exhausted, apply a second quantity, containing six drops of silver solution to the drachm. This will rapidly intensify and complete the development. Now wash and fix with cyanide of potassium, five or six grains to the ounce of water, or with strong solution of hyposulphite of soda. When the fixing solution has removed the greater body of the yellow iodide, swill off, and apply again only to those parts where it still remains, as a prolonged action of this agent weakens the negative too much. The plate may now be dried, and varnished with the ordinary French varnish. If time is not an object, very beautiful results may be obtained by developing with a saturated solution of gallic acid, to every ounce of which ten drops of the nitrate of silver solution have been added. This must be conducted in a flat dish, as the development may occupy an hour or more.

CELESTIAL AND INSTANTANEOUS PHOTOGRAPHY.

By Warren De la Rue, Esq., F.R.S., F.R.A.S., &c.

(Continued from page 252.)

Desiderata in the Machinery for Driving the Telescope.

As in the production of celestial photographs some seconds of exposure are requisite, it is essential to have a clock-work driver to the telescope, which works uniformly and smoothly, and which is also capable, when lunar pictures are to be taken, of ready adjustment to the ever-varying lunar time. Lunar time, it will be recollected, differs from sidereal time, in consequence of the moon's variable motion in her orbit in a direction opposite to that of the apparent diurnal movement of the stars. A driving clock, if adjusted to follow a star, must be retarded therefore, more or less, in order to follow the moon. In my own telescope, this is at present effected by altering the length of the conical pendulum or friction governor, thus altering the time of its rotation (or double beat), and this plan, or some modification of it, is universal. My experience, however, has pointed out several inconveniences in thus changing the speed of the governor or pendulum, and it is my intention to make such alterations in the construction of the clock as will enable me to alter the going of the telescope without changing the rate of the pendulum. This I propose to do by substituting an arrangement, similar to that known in mechanism as the disc and plate, for the wheel-work now connecting the machinery of the clock with the pendulum; the disc and plate being capable of producing a variable motion, according as the disc is nearer to or farther from the centre of the plate. The pendulum will, by the proposed plan, be driven by frictional contact, and, having employed this system in other machinery, I feel persuaded that its application to the clock-driver will not be attended with difficulty or inconvenience.

The moon, besides her motion in right ascension, has also a motion in declination, which is greatest when she is situated in one of the nodes formed by the intersection of the plane of the

moon's orbit and the plane of the earth's equator, and is least when situated 90° from these nodes, where it vanishes. As this motion is at times very considerable, it is evident that, with a telescope made only to rotate round the polar axis, the best results will be obtained, all other circumstances being alike, when the motion in declination is at zero. Assuming that, on the average, 15 seconds are necessary for taking a lunar photograph, the moon may have shifted upwards of 4 seconds of arc in declination during that period; and evidently many details would be lost and the others considerably distorted. In order to ensure the most perfect results under all circumstances, it is desirable to give a movement to the declination axis of the telescope simultaneously with the movement of the polar axis. Hitherto, so far as I am aware, no means have been devised to effect this, but the requisite adjustable motion might be transmitted by means of the disc and plate above described, from the driving-clock, although its pendulum moves with a uniform velocity.

Lord Rosse's Method.—In my original method of taking the pictures by means of the sliding eye-piece before spoken of, both motions in right ascension and declination were provided for by adjusting the slide in the diagonal parallel with the moon's apparent path. Lord Rosse, at a subsequent period, applied a clock-movement to such a slide, and made some experiments in celestial photography;* but, the telescope being required for other special purposes, it appears that they were not long continued. This motion of the plate-holder does not meet all the exigencies of the case, but if one of his magnificent reflectors were arranged to move bodily along a guide adjustable in the direction of the moon's path, by means of some such mechanism as I have alluded to, I believe that lunar pictures might be produced of exquisite beauty, because defects in the collodion film and the glass plate would be of less consequence than with telescopes of shorter focal length, the image being larger in the ratio of focal length; for example, even with the three-foot instrument it would be 3 inches in diameter.

(To be continued.)

* Monthly Notices of the Roy. Ast. Soc. vol. xiv., p. 199.

ON THE QUESTION OF ENLARGEMENT.

By M. Silbermann.

The discussions that have lately taken place on the enlargement of photographs demands some attention. I have observed with regret that operators appear in general to be very ignorant of the appliances long since recorded in the annals of science. Thus the construction of instruments for magnifying images of all kinds is of very remote date. First came the simple magnifying glass, and then the microscopes of various kinds followed:—first simple; afterwards with acromatic lenses; then all those instruments intended to project the image on a plane surface, such as the megascope, the magic lantern, lucernal microscope, solar microscope, &c., of which the camera obscura, the pronopioscope, and the photographic apparatus are only variations or reproductions.

We know that in a positive lens there are two points upon its axis—one in front, the other behind—the distances of which from the lens are connected together by a simple formula, by means of which, knowing the principal focal distance, it is easy, for any position whatever of an object on the axis of this lens, to determine at what distance on the other side of it the image will be reproduced. These two distances are complementary to each other, and the points on the axis where the rays meet are called the conjugate foci. We say, as a fundamental rule, when the object is between the principal focus and the double of this focus the image will take any enlargement, from the natural size to the infinitely great. So, also, if the object is removed double the distance of the focus towards infinity, to become at length, in its turn, infinitely small in relation to the object.

We have only here to consider actual enlargement. For this purpose we must regard our photographic apparatus in a reversed position, or as if the camera was in front of the lens instead of behind it: the screen that receives the image remains in its place in which to fix the object, which is in this case a photographic proof on a plane surface. The new camera, of large dimensions in comparison with the old one, according to the size of the pictures we desire to obtain, will carry at its anterior end the usual arrangements for the focussing screen and sensitive plate.

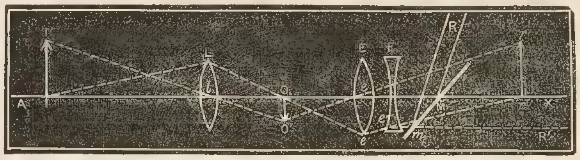
This general arrangement was realised in the megascope, and in the solar and lucernal microscopes, long before our new art came into existence, and we may appropriate what we find useful in them, viz.:—

1. For opaque objects, as proofs on paper, the lighting of the object to be reproduced is effected by plane mirrors, or by concave mirrors, which project a greater quantity of light on the object, to illuminate it better. As the object is opaque, all the rays of light the object reflects back proceed from this object by diffusion, like those which constitute its image. This coincidence between the point of departure of the illuminating rays, added to those of the object, always produces a distinct image, when the lens is well constructed, the focus properly adjusted, and the body quite flat.

2. But when the object is transparent, like the picture on a collodion plate, then its too highly-polished surface sends but very little diffused light, and the circumstances of the preceding case no longer exist; then the borrowed light must necessarily pass through the collodioned glass. Here, then, begins the difficulty of arrangement, which can no longer be a simple plane mirror, because the rays it projects on the back of the glass traverse it in a straight line, and they have their focus at the principal focal distance; then they cross those of the image of which the focus is farther off; and, in consequence of the non-coincidence between the two foci, the image is confused, sharpness no longer exists, and the focal effect is destroyed by extraneous light.

M. Charles, to prevent this effect, and to restore that of diffused light, placed a lenticular illuminator behind the object, first adjusting it so that the additional rays of light formed their focus in the same place as the object to be reproduced. It was afterwards recognised, first by M. Charles, and then by micrographists, that it was not enough to have a perfectly clear image, but that, besides a perfect centering on the same axis, it was necessary that the rays concentrated upon the object should proceed perfectly in harmony with those of the object, and this harmony is only strictly obtained when the illuminating lens, by its size and position, sends all its rays to the object in such a manner that each forms the continuation of that which in part constitutes the image.

The theoretical representation of this effect is given in the annexed diagram:—



Upon the axis, A X, is the object lens, L; the object, O, having its conjugate focus or image in I. I suppose that the illuminating lens, E, is of the same focus as the object lens, and that the distance $O\,e = O\,l$. In this case the illuminating rays must emanate from the point, r, of a luminous body, $r\,r'$, having the same size and extent as the plate in I I′, and be at a distance $O\,r = O\,I$, if it be easy to procure such a well-lighted and well-lighting surface. But as this is scarcely possible, as we have only the parallel rays of the sun and white clouds at our command, we are obliged to collect together the parallel rays, R, by means of a plane mirror, M, placed upon the axis; but these parallel rays, sent by the mirror, will receive a modification in their transit before arriving at the illuminating lens, at which they will arrive as if they had set out from the point, r, on the principal axis, or from the body, $r\,r'$. To do this we must have a concave lens, E′, the divergent power of which must be exactly that required by the difference of the path $e'\,r$. If this condition be realised, we can recognise it; for when we regard the image at I, we then perceive a very sharp representation of the lighting body, at the same time we see the very clear image of the object lighted. This shows that the two kinds of rays are well crossed in O, and that they proceed in harmony from thence to I. We have not then to fear the effects of interference which generally fringe and multiply the lines.

It is understood that the two condensing lenses, E, E′, must be a well-selected achromatic combination. But we see that theoretically we must have a different condensing system for each conjugate focal distance. To obviate this inconvenience in practice, that is, to have less occasion to fear the injurious effects of a given illuminator in cases nearly actual, we make the arrangement of the two condensers moveable, and convert the first lens of it, E, into an achromatic lens. Thus we obtain a tolerable play within and beyond the absolute limits.

Meetings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

We have to remind the members of the above Association that the next ordinary meeting will be held, as usual, at Myddleton Hall, Islington, on Wednesday, the 26th instant, at eight o'clock in the evening.

Gentlemen wishing to join the Association will please to communicate with the Honorary Secretary—Mr. John Barnett, 9, St. Peter's Terrace, Islington, N.—before the evening of meeting, and, on election, they will be entitled to all numbers of The British Journal of Photography published between the 31st of March last and the end of March, 1861; and also a copy of the presentation photograph, when ready for distribution.

The Committee will meet, for the transaction of business, on Wednesday, the 26th instant, at half-past seven o'clock.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A meeting of the above Society was held in the Rooms of the Literary and Philosophical Society, 36, George Street, on Wednesday, the 5th inst.,—Professor Williamson presiding.

Mr. Isaac Horsfield, Mr. John H. Gilbert, and Mr. J. Kershaw were unanimously elected members of the Society.

The Hon. Secretary laid on the table a large collodio-albumen print, presented to the Society's portfolio by Mr. Joseph Sidebotham, also four large prints presented by Mr. H. Petschler, taken by his new modification of the collodio-albumen process, all of which were much admired.

The thanks of the meeting were given to those gentlemen for their donations.

The Chairman said, if the members of the Society would, in their leisure time, take little picturesque bits of foreground, they would be of much value, and by so doing they would confer a great boon upon artists.

Mr. Sidebotham said artists were often glad to receive assistance from photographers, but, at the same time, were very much in the habit of sneering at their productions.

The Chairman said he could not agree with Mr. Sidebotham on that point; at all events, such was the exception, for he was acquainted with several artists who had frequently acknowledged the valuable assistance they had received from photography, and had expressed a strong desire to possess such photographic scraps to assist them in their studies.

Mr. Mabley said that the Society had no honours or decorations to bestow upon those members of the Society who had distinguished themselves by discoveries which they had made, and he thought, in the case of Mr. Petschler, who had lately made known to them the very novel and important facts in his modification of the collodio-albumen process, it would be a very graceful and proper marking of their appreciation, if they were to elect him forthwith a member of the Council of the Society, there being a vacancy at present. He should therefore propose that Mr. Petschler be elected a member of the Council.

Mr. Sidebotham seconded the motion, which was carried by acclamation.

Mr. Mabley said the editor of The British Journal of Photography had, in his article on Mr. Petschler's process, rather unfairly put the matter before the public. He there insinuated that the matter was only a variation of the Fothergill process; and, though he stated that he did not wish to depreciate the novelty of Mr. Petschler's discovery, yet he did at the same time try rather to detract from some of the merit which he (Mr. Mabley) thought Mr. Petschler was entitled to. No one could fairly deny that the facts disclosed by the communication of Messrs. Petschler and Mann were entirely novel.

Mr. Sidebotham said he quite agreed with Mr. Mabley in his remarks, and thought the matter was not quite fairly put in the article which had appeared in the Journal. As important discoveries were really very rare in photography, it was only proper that the persons communicating them should have the full credit given them.

A general discussion then took place upon the subject of the new process, when it was suggested that some further experiments should be made in a systematic way before the next meeting.

The Chairman called upon Mr. Parry to communicate some experiments which he had been making with reference to the aceto-nitrate bath, as used in the collodio-albumen process.

Mr. Parry then read a paper *On the Action of the Aceto-Nitrate Bath in the Collodio-Albumen Process.* [See page 267.]

After reading his communication, Mr. Parry exhibited several stereoscopic negatives, illustrative of the remarks in his paper.

Many of the members thought the results of Mr. Parry's experiments very important, if a weaker bath than was generally used was sufficient, though the increased liability to blisters was a serious difficulty. A general discussion took place on the subject of the cause and means of preventing the blistering of the film in the collodio-albumen process.

Mr. Griffiths said it had occurred to him, though he had not yet tried it, that developing with alcohol, instead of water, would prevent blisters.

Mr. Neville stated that he had long since tried the plan suggested by Mr. Griffiths, but could not at all succeed in obtaining any trace of a picture.

It was generally stated by Mr. Sidebotham, Mr. Mudd, and other members, that the best plan to avoid blisters was to bake the plate well previously to sensitising the second time, and if the plates had been kept sometime in the half prepared state, always to take the precaution of heating them again before sensitising.

Mr. Mudd said he had lately sensitised some plates which had been kept some time. Some he warmed at the fire, before putting in the aceto-nitrate bath; but he did not take this precaution with all, and those only which he had not so dried, blistered.

Mr. Mabley exhibited some negatives which he had lately taken at the seaside, on some of the plates lately prepared by Dr. Hill Norris, which were said to be as quick as wet collodion. The pictures he produced he had taken in from three to five seconds, and thought this fact was the most wonderful thing which had lately come out in relation to the dry processes. He also developed a plate which he had exposed for only a few seconds that morning at Blackpool.

The thanks of the meeting were given to Mr. Parry for his communication, and also to the chairman for his services, when, after a very interesting meeting, the proceedings closed at a later hour than usual.

LIVERPOOL PHOTOGRAPHIC CLUB.

An ordinary meeting for the month of the above Society took place at the residence of Mr. Forrest, on Tuesday, the 11th inst. There was a full attendance of members.

Mr. Berry exhibited a picture of one of the new street railway omnibuses, thickly clustered with passengers. This was taken with a view lens in the short space of five seconds, without the aid of Maxwell Lyte's instantaneous fluid. The portraits of a large number of the passengers were readily recognised by the several members. He also showed several proofs of negatives of the sun's disc during the late eclipse: these were about five inches square, and exceedingly clear.

Mr. Helsby, lately returned from South America, presented a very clear positive, half-plate size, that had been very successfully transferred to paper. After being blacked at the back with the usual asphalte varnish, the separation from the glass was accomplished by means of varnish of his own composition, which had the effect of making it adhere so closely to the paper that it left the glass without crack or break in the film.

Messrs. Cook laid before the meeting some very clear negatives, of stereoscopic size, prepared according to the method of Messrs. Petschler and Mann, and were disposed to think highly of the principle. The pictures were sharp, clear, and forcible.

Mr. Corey narrated the particulars of some very satisfactory experiments he has pursued on the subject of plates preserved with resin. Having tried them according to the plan recommended by Mr. Glover, at a recent meeting, but with indifferent success, he was about to lay it aside; but the lucid remarks of Mr. Hardwich, in the last edition of his work, caught his attention, where he observed that he advised, what had never been tried by any of the members, viz., redipping in the bath after exposure. This very judicious suggestion tempted another trial, and the result far exceeded his most sanguine expectations. There was no longer a cold, weak, spotted negative, but every part rushed out in full vigour and brilliancy. Nay, more, the same collodion that would produce a tame and medium picture, would now present one of the greatest intensity. Nor was it confined to the same sample, for subsequent trial proved that any collodion that would produce a negative of ordinary quality, provided that it was prepared with pyroxyline of the proper quality, that is to say, prepared with strong acids at rather high temperature, with a brief immersion, so as to give a short pulpy film that would adhere on drying, the rich effect always followed. But it must be observed that a slight washing was not efficacious for a clear picture. A large jug of water must be emptied on it with some force, so as to remove all trace of the free nitrate, and here he was prepared fully to coincide with Mr. Hardwich when he says, at page 375 of his work, after observing in the previous page that this removal was all that could be looked for by the washing, but "that it is not so; for the image" [in full vigour] "cannot be developed after so short an exposure when the pyrogallic acid and nitrate of silver are mixed and applied simultaneously to the plate" * * * "hence that the second dip in the bath has to do, not only with the reduction, but the formation of the image." Now he (Mr. Corey) was entirely of that opinion; and he was further borne out by the experiments of Messrs. Petschler and Mann, who, by their addition of chloride, seek more effectually to get rid of the free nitrate of silver upon their surface, which, by its inevitable crystallisation, would break up the surface, and then, just before exposure, get rid of the insensible chloride; but could only then produce a negative of feeble quality, for lack of the integral part so necessary to the existence of a first-rate negative, with the further drawback of having, as it were, to resensitise the plate by the subsequent washing, a short while before exposure. On the other hand, these were ready to be snatched up at any moment upon the appearance of the genial beam, or the unexpected coming across a favourable object; but if no other recommendation offered itself, the time of exposure would supersede all others, for in every other description of washed plate a range of from five minutes to even twenty was requisite; whereas in no case had more than one minute with sun, and three minutes without it, been required.

Mr. Berry was also of opinion that the restoration of the free nitrate by dipping had some specific effect in the re-formation of the latent image,

which could not be accomplished by mere mixing of the silver with the developer.

Mr. Charles Jones exhibited a very perfect negative by this method; but, not intending to redip, had exposed six minutes.

The Rev. Thomas Banner, during the meeting, developed two stereoscopic plates exposed that day, one of them by re-dipping, the other without. Though both were exposed the same time, that which was re-dipped exhibited every appearance of having been over-exposed; the other was rightly timed, but as it was a very light day the exposure was short in each case.

Mr. Helsby was disposed to think re-dipping exerted some occult influence, for he had tried forcing over-done positives, developed with iron, into negatives, by a further treatment with pyrogallic and acetic acids, but never successfully until he had heard of this; he then brought out rather deeply with iron, washed his plate, cleared with cyanide, and dried thoroughly. After this he dipped it again into the bath, and now upon applying the two acids as before, a very deep, clear, and intense negative came out.

The members separated, after a most satisfactory meeting, at a late hour.

New Books.

On the Invention of Stereoscopic Glasses *for* Single Pictures, *with Preliminary Observations on the Stereoscope, &c.*

By T. Wharton Jones, F.R.S.

(London: John Churchill, New Burlington Street.)

It is not often that we have been more impressed with the truth of the saying, "the wish was father to the thought," than when reading the pamphlet now before us, which is published with the view of showing how a single picture may be forced into producing stereoscopic effects by inspecting it through lenses of peculiar construction, each of which causes a particular kind and amount of distortion.

The fact that Professor Jones, a gentleman intimately connected with investigations relating to the physiology of vision, should have failed to detect the weak point in his own theory, is one of those striking instances of mental obliquity of vision so frequently seen in the enthusiastic pursuer of a cherished idea, who not only ignores difficulties, but also makes light of impossibilities.

The attempt to produce stereosity in one picture may be properly classed with those for effecting perpetual motion, aptly described as getting into a basket and trying to lift yourself up, basket and all, by the handles: it is, and ever must be, simply *impossible.*

In asserting this we do not mean to affirm that a slight *semblance* of stereosity may not be produced under certain circumstances by aid of the lenses contrived by Mr. Jones, if brought to bear upon *skeleton diagrams;* but *true* stereoscopic effect can never by any possibility be educed from a single *picture.* The reason is evident when we reflect that *an object in the foreground eclipses a different portion of those in the background, when viewed by each eye alternately;* and, as in a single picture on a plane surface this condition cannot be fulfilled, the idea of objects in different planes cannot be suggested.

In Professor Jones's remarks upon the stereoscope we find him somewhat behind the age, or surely he would not have written the following:—"Sir David's improvement, admirable as it is, belongs merely to the arrangement by means of which the two perspectives of the slide are presented one to each eye separately. It consists in substituting for the ordinary convex glasses the two halves of one, placed with their circumferential edges next each other."

We need scarcely inform our readers that the "*improvement*" is not now regarded as such, and that in the higher class of instruments whole lenses are as a rule employed; and when, for economy, semi-lenses are still used, they are so placed that the pupils of the eyes look through that portion most nearly approximating to the centre, thus avoiding, or reducing to a minimum, lateral distortion.

We can by no means assent to the correctness of the theory of stereoscopic vision as propounded by the author. We do not see the slightest necessity for any such suppositions as "the mental combination of the two into one." His explanation of the reason why an image though inverted upon the retina is referred correctly to an erect object by the mind, is perfectly clear and sound, it being, as he says, "referred in accordance with the law of visible direction outwardly," and, consequently, the same point being seen simultaneously by both eyes with *an outward reference*, runs no more risk of making a double mental impression than the same point touched simultaneously by both hands.

Again, when treating of the corresponding points of the two retinæ, our author states:—"It is not an indispensable condition of single vision that every part of the impression on the two retinæ be made on exactly corresponding points." We think this statement is scarcely true without limitation, and the illustration given to meet the hypothesis is by no means satisfactory.

A very lucid and perfectly conclusive demonstration of the laws of stereoscopic vision was published a year or two back by Dr. Tyndal, in which that gentleman showed that, as by the degree of convergence of the optic axes the relative distances of various points are accurately conveyed to the mind, while their relative positions are determined by the law of visible direction, all the requisite conditions are strictly fulfilled for ascertaining mathematically the absolute *locus* of each individual point (that in fact a complete system of triangulation is carried out), and that the information is gained by a series of successive but rapid adjustments of the optic axes to each point of importance in the subject before the spectator.

That Mr. Jones is well aware of the power of determining the distance of objects by the two eyes no one could of course for a moment doubt; and this the following extract will prove:—"The faculty of perceiving the three dimensions of space with the two eyes implies the faculty of recognising by the same means the distance and position of objects looked at with the optic axes in a state of convergence." With such a proposition before him, it is to us perfectly marvellous that he does not perceive that in a single picture—however much it may be distorted in opposite directions to each eye, either by reflection or refraction—the amount of distortion of the back and foreground objects in *the same line of vision* being equal, and consequently the convergence of the optic axes in order to view them being also exactly equal, the fact of their being located at an equal distance must of necessity be revealed, and therefore stereoscopic illusion destroyed.

We have admitted a possible case of the *semblance* of stereosity: it is that of a white diagram representing a single object in outline *upon a black ground;* the latter, resembling mere space, would not reveal the fact that the back and foreground objects occupied the same plane.

We readily admit the ingenuity of the plan proposed by Mr. Jones, and can easily understand how he has allowed his enthusiasm to run away with his more sober judgment; but we must bring in a verdict of "not proven," nevertheless.

Letters to a Photographic Friend.

No. V.

My dear Frank,

In my last letter I omitted to tell you what I saw at Solomon's, in Red Lion Square, so take this opportunity of doing so.

You know what an everlasting source of anxiety the focussing glass is to the photographer when *en route*, or in the field, in districts where graziers are more plentiful than glaziers, and opticians are known not, lest, when placed aside on the ground or elsewhere after the operation of focussing has been completed, some accident to it should place him *hors de combat.* To get the focussing glass out of harm's way, Mr. Solomon has introduced the following simple and efficient arrangement in a camera he brought under my notice:—The focussing glass has two springs screwed to the back of the frame, and which rest against bearings in such a way that they force the focussing glass into the position the plate-frame occupies when a picture is being taken. The top of the frame is bevelled, and, if the plate-frame be forced downwards on it, the springs yield, and the focussing glass is forced behind the plate-frame as it slides into position: thus you see the focussing glass need never be withdrawn from the camera, as in the usual method of mounting, so that it saves time as well as risk, and it only entails an additional length behind the groove in which the plate-frame slides equal to *the thickness* of the focussing glass. In the camera examined this was about one inch, but it might be much less. When the plate-frame is removed, the springs, of course, force the focussing glass again into position ready for the next view being adjusted. I only know of one other way of protecting the ground glass when out of use, and that is by providing a compartment for it in the roof of the camera, from which it can be withdrawn, and then, by means of a hinged arrangement, be lowered into position for focussing the view—which done, it is raised and pushed back again; but this can only be accomplished in solid-framed cameras, where a space equal to the size of the focussing frame can be provided in the roof of the camera. But as it is evident bellows and other collapsable forms will, from recent improvements in their construction, come into general use, the method introduced by Mr. Solomon is more generally applicable. Another point in the camera under consideration was, that the plate carriers, instead of being made of wood, were constructed of slate, with silver wire corners for the glasses to rest upon. I think, on the score of cleanliness and absorptive qualities, these slate or "stone-plate carriers" must be better than wooden ones: they are equally neat, but perhaps a trifle heavier. These are made to suit cameras of all sizes.

Another contrivance brought under my notice was a capital plate-cleaning frame. It consisted of a board, to the under side of which a bead was attached, so as to secure a firm rest against a table or bench; the upper side was covered with plush, and, round the left-hand and top side of the board, a beading was screwed that

presented an inner edge somewhat less than the thickness of an ordinary glass plate. At the left-hand corner of the board nearest the operator a wooden bar worked on a screw, so that a glass of *any size* less than that of the board might be clamped by placing it in the right angle formed by the beading, and then pressing the moveable bar against its lower angle. This "lever glass-cleaner" is at once cheap and simple in construction, and greatly facilitates the not over-agreeable operation of plate-cleaning.

In connexion with this contrivance, I was shown the action of "Cowderoy's Diamond Polish"—a liquid for instantly cleansing glass without washing, and said to be free from fixed alkalies, salts, or anything else injurious to the bath solution. This was rubbed over a very dirty plate with a cloth, and the liquid certainly did its work most efficiently.

On starting eastward, the first photographic house that fell in my way was that of Messrs. Burfield and Rouch, at the corner of Norfolk Street, Strand, where I found a very portable camera, conveniently contrived to economise both weight and bulk. It consisted of a base-board, made in two parts, framed and grooved, so as to work like a telescope joint, and which could be extended or contracted, by means of an endless screw. To the widest portion of this board the wooden framework forming the back of the body was screwed, whilst in the narrowest or front portion a piece of mahogany, that carried the flange-plate of the lens, was hinged so that it could be turned up at a right angle to the base-board, and firmly fixed by means of two brass struts, clamped by binding screws. From within the back frame a collapsable conical body, made of thick black plush, was drawn forth, the front portion of

FIG 1

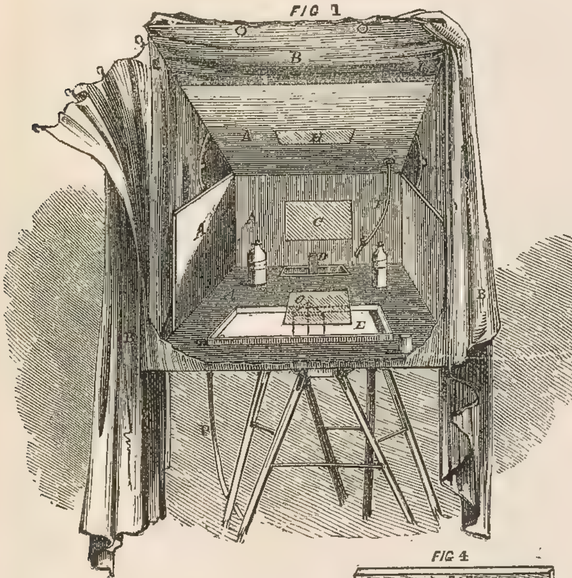


FIG 4

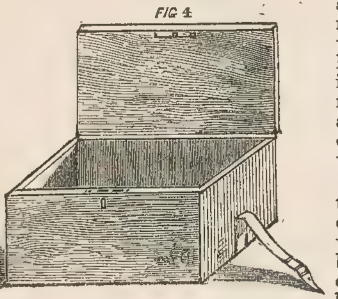

FIG.2

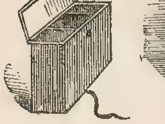
FIG.3



which was attached to a square board, that dropt into a groove in the upright behind the flange-plate. The body received support by means of square iron-wire frames, placed here and there within it, and elastic bands stretched from back to front at the four corners. The focussing was effected from the back, by means of the endless screw acting on the two portions of the base-board; and, when stretched to its full range, this camera was rigid at all points. When the base-board was shut up into the shortest range it corresponded in size with the back frame, and packed into it, closing over the collapsed body, and forming a lid to the whole. The focussing-glass and plate-frame packed within the camera on the opposite side to the base-board, so that all the parts of a ten by eight inches camera packed into a thickness of about four inches. The plate-frame had a cell beneath the plate-carrier, extending the width of the frame, for the purpose of receiving the drainings of silver solution: this seems a good idea.

Messrs. Burfield and Rouch had also a very convenient form of outdoor "portable operating chamber," which, I trust, by aid of pen and pencil, I shall be able to give you a good idea of. *Fig.* 4 represents the chamber when put up as a packing-case; for plates ten by eight inches the dimensions are twenty inches wide, ten inches high, and twelve and a-half inches from back to front: with the covering, &c., this weighs seventeen pounds. This box is screwed on to the tripod-stand, in such a way that the lid forms the front part of the work-table. The front portion in *Fig.* 4 (where the keyhole is inserted) is then pushed up, and kept in a slanting position by means of quadrant-pieces and knee-jointed brass rods, as shown in *Fig.* 1—so as to form the roof of the chamber or tent, which is further extended by means of two stout brass wires and a cross-bar being fitted in to holes in the edge of the lid. Over this wooden portion a covering B, impervious to actinic rays, is fitted, so that a part falls in folds over the back of the operator, and effectually closes out the light from the interior. Yellow light is admitted by means of an orange-glass window C, which slides in grooves, so that it can be used as a shutter to admit white light or air, as may be required. Ventilation may also be obtained when needed by the trapdoor H. The chemicals are packed in a divided tin box, *Fig.* 3, which also acts the part of a reservoir for water, and is then fixed on the top of the chamber, and the liquid conveyed into the interior by means of a flexible tube, closed with a spring clip F. A bag at D receives the bath-holder, whilst a portable tray E and tube P receives and carries off the waste liquids. When the tent is arranged, as in *Fig.* 1, a table space is provided of twenty-one by thirty-four inches, and ample ventilation is secured. It can easily be erected by one person, and adjusted to any height desired. An extra support is given to the tripod on which it is placed by means of metal bars passing from one leg to the other, and clamped fast by screws passing through slots in the metal and this greatly assists in preventing the whole affair being affected by wind. I should certainly expect that one could work with the greatest ease and comfort within its walls.

In passing through Fleet Street, my eye fell upon a carbon filtering apparatus in a shop window. Thinking this invention might be serviceable in the photographic laboratory, I went in to overhaul it. I found that the sponge, or porous stone, &c., usually employed in filtering apparatus, was replaced by a ball of "moulded carbon." This, from its porosity and its known peculiar action on decaying matter, might be expected to give very satisfactory results; and Dr. Hassall states, in his report on these filters, that they deprived foul waters of sulphureted hydrogen, urea, and organic matter held in solution, as well as animalcules, confervæ, and earthy substances held mechanically in suspension, and he regards these as the most valuable and efficient filters yet constructed. These may be had of the Patent Moulded Carbon Company, at prices varying from three shillings to two pounds ten shillings. The most useful form for photographic purposes would be figs. 5 and 6 in their list, and costing ten shillings for one of a capacity of one gallon, twenty shillings for one of three gallons, and thirty-five shillings for one of six gallons.

Another form consisted of a carbon ball, to which a flexible tube was attached. On placing this in a vessel of water of questionable purity, and sucking the free end of the tube till water was drawn up, and then dropping the end lower than the ball, it began to act as a syphon, and the water was drawn over bright, tasteless, and apparently pure. This form would be very convenient for use when travelling, as the ball with its tube occupies little space, and can be readily applied to any vessel when needed. Dr. Hassall states that these carbon filters act not only mechanically, but chemically, and have the power of abstracting a large portion of many substances held in a state of absolute solution, as in the case of acetate of lead. A solution of sugar, having a specific gravity of 1012, after filtration was reduced to 1004.

The next photographic house on my route was Shepherd and Co.'s, at the corner of Farringdon Street. Here I found a camera, in principle exactly like that I had examined at Messrs. Burfield and Rouch's, the plan of which had been placed in Mr. Eidman's hands by Mr. Ramsden, of collodion celebrity—the only point of difference being that the end of the conical body was permanently attached to the flange plate, and this was fixed in position at the end of the telescopic base-board by means of a triangular bar fitting into an aperture of corresponding shape, which could be fixed at any height by a clamping screw. This also allowed of the lens being adjusted for foreground, and the body was made of waterproof cloth, instead of plush, as in Messrs. Burfield and Rouch's instrument.

I also took the opportunity of examining "Jeffery's Excelsior Dark Tent." The frame of this is put together so that it folds up like the letter W, the inner folds of which when pressed down form the table portion of the tent, and the outer limbs are kept at right angles to the table by means of another hinged frame that fits on in front. This framework is clamped on to a stand, and over it is stretched a black twill cover, with a yellow window let into the front portion. To the upper part of the side frames are fitted a contrivance for ventilating the tent. When folded this roomy tent occupies the space of a large carpet-bag. There is one peculiarity about this arrangement that I must not omit to call your attention to—viz., that a provision is made for fixing the lens in the front of the tent, a little above the table; whilst behind the lens, attached to the table, is a sliding board, carrying a hinged plate-frame, turning up at a right angle to the table, so that the tent may be employed as a camera as well as an operating room. To a *travelling portraitist* this arrangement would be valuable, as the lens could readily be pointed at a chair on which the sitters would always take their place. But for landscape photography such a method would be *very* inconvenient, as I know from experience; for, some years since, I contrived a framed tent, with a camera attached, so that it could be manipulated from within. This tent was mounted on an axletree carrying a pair of large light wheels; but, although this possessed more freedom of motion than a tripod-stand admits of when pointing at fresh views, it was too cumbersome to allow of its being placed in many positions, and the covering of the tent catching the wind imparted a very undesirable tremor to the lens and plate. There is little question but that the camera and tent should be kept distinct, except for the purpose I have previously indicated, and then it can be placed in a position so as to be shielded from the wind.

This letter has now run to such a length that I must wait till I can again find leisure to inform you what I saw at the other establishments in Rowland Hill's E. C. district.

So believe me,

Yours everlastingly,

SIMEON HEADSMAN.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

Returning to the face, hatch a thin pale tint of blue (cobalt) over the receding or rounded portions of the face, and about the jaws; soften the outlines of all shadows, keeping the edges cool and grey; destroy all hardness in the lines of the eyes, mouth, hair, ear, &c., and continue working upon the flesh until, in point of roundness, gradation, softness, and fidelity of resemblance to nature, your eye is tolerably satisfied. Then work up every other part with a similar feeling and result, with extreme care, tenderly preserving the more subtle transitions from light to shade. If you are colouring on the salted paper, the application of the burnisher, as already described, will be frequently necessary, during progress, to keep the surface hard and smooth.

You will discover frequently that while in the light in which it was painted your picture looks soft, smooth, and even, in the reverse light it will appear coarse and rough: to avoid which effect, in the course of your work turn the picture upside down now and then, and even up the colours with very tender, delicate touches, taking great care not to deepen the colours too much by working into the interstices. Preserve the proper proportions of depth or tone with the greatest care.

The instructions given relate to painting a fair complexion: for a darker one use, for the flesh-wash, Venetian red and Indian yellow, keeping the shadows and half-tints greenish if the complexion incline to the sallow, or purplish if the complexion possess more of the red hues; or, if the complexion be very dark, use a little burnt sienna or yellow ochre in the flesh-wash. [See previous remarks upon the half-tints and shadows of flesh, and also the "maxims."] It would be so difficult, without models, to convey any idea of all the many modifications of colours and tints necessary for imitating the vast variety of complexions, that these few hints, with the many others already given, must suffice. With study and practice the student will duly learn to secure all the effects of nature; and without such aids what I have said already is more than enough for his guidance.

TINTING.

A less elaborate method of colouring, which will demand less time and study to secure a pleasing effect, may be adopted as follows:—

Commence by working over the retiring shadows and half-tones with washy touches of cobalt, mixed with a very little Naples yellow, making this tint more or less blue according to the character of your sitter's complexion. Then work over the deeper shadows with a little Indian red, combined with a very slight touch of vermilion. Now take a little pink madder and put the colour into the cheek, lips, &c. When these colours are dry, carry over the whole, with a light touch and a rather full brush, a general wash of Naples yellow and pink madder, or Venetian red and Indian yellow, with a touch or two of Chinese white, or madder pink and Indian yellow, or what other mixture may seem best for producing the complexion to be imitated, keeping the colour clean and bright, and not too deep in tone. Whilst this is drying, a wash of any of the colours for hair which have been already given may be applied, but be careful not to use it too fluid, lest it should stray into the flesh tints and destroy their purity and beauty. The eyebrows and lashes may next be touched in with a little sepia, or sepia, lake, and indigo mixed to a rich purplish or blueish black, preserving their softness and delicacy with the greatest care. With this last tint touch in, vigorously, the pupil of the eye, and outline the iris of the same with a little indigo or sepia: the former if the eye be blue or grey. A little vermilion and madder pink, or madder pink or lake, as the model will determine, may be stippled over the lips; and a little brown madder and pink used to strengthen the deeper portions of the shadows, used with a little gum water. With a delicate stipple now proceed to even up or deepen the tints, adding a little cobalt to the greys, a little cobalt and madder pink here and there [see previous directions with reference to the violet and blue tints in the flesh], and a little Indian red to warm out the deeper shadows. Tinted pictures are generally left with the flesh only coloured.

ORNAMENTS, DRAPERY, ETC.

Gold.—Lay in with Roman ochre; for the shadows, use a little bistre and burnt sienna; for the high lights, a little yellow ochre and white, with a touch of cadmium; the highest or more sparkling high lights, with a little cadmium and white;* reflected lights, orange chrome.

Silver.—Local colour, black, white, and burnt sienna; shadows, cobalt, sepia, and madder pink; high lights, pure white; reflected lights, Naples yellow.

Pearls.—Local tint, ultramarine, sepia, and lake; burnt sienna and ultramarine for shadows; ochre and white for reflected lights; high lights, pure white.

Lace.—It is as well to paint this over the colour it is supposed to cover, this colour being painted as if in shadow. The local colour for lace is a yellowish white, upon this place the lights with white. Use sepia with a touch of cobalt for the shades.

Feathers.—Say the feathers are white: use for the local colour ultramarine, ochre, and madder pink; the same, deeper, for the shades; and pure white for the high lights. Carefully avoid harsh touches in laying on the lights, working with a series of faint and tender touches to preserve an appearance of feathery softness and looseness in the particles. For the stronger shadows and markings use a little warm sepia.

Velvets.—Black velvet: local colour black, with a little gum; lights white, lampblack, and a touch of French blue; shadows, lake, sepia, and indigo, with gum; highest lights, white, black, and a touch of blue, using more white. Put in the fainter reflected lights with the colour for the lights, but glaze over them, when dry, a little madder brown and gamboge. Keep all the lights soft, but strong. For green velvet use prussian blue, cadmium, and Venetian red as the local tint, laid on with a good body; use white, Prussian blue, and a little gamboge for the lights; white and French blue for the highest or brightest high lights; and glaze over

* Increased brilliancy of the highest lights may be obtained by laying the white on first, and, when dry, glazing it with a little gamboge.

the whole with sap green. Crimson velvet: lake and madder brown for the local colour, laid on with a good body; shades, lake and sepia; high lights, white and a little vermilion; glaze with carmine. [For a more detailed description of the method of treating velvets refer back].

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

J. B. and Rosalind.—The replies to these correspondents being of a character not likely to benefit or interest others, will be sent per post as soon as the author has made the inquiries.

Arthur E., Colchester.—The old old fault—impatience. Don't hurry, I say again. I really cannot judge from the specimen you sent—try again.

Chromo.—I have been from town, but will write to you in a day or two.

An Unanswered Inquirer.—I must solicit your pardon for overlooking your note. I should not suppose that Chinese pigments possess any absolute superiority to our own, but they are certainly more elaborately ground, and altogether better prepared. I should have thought your plan a good one; however, try a varnish made with equal quantities of Canada balsam and clear white resin, dissolved in turpentine. With reference to your last question I have consulted Sir Charles Eastlake's work, and find that the varnish so highly recommended for oil paintings, as retaining its purity of colour and transparency better than any other, is composed of the best Olio d'Abezzo, slowly dissolved with gentle heat, to which is added rectified petroleum, the whole being well stirred while mixing. It is applied, while warm, to a surface also warmed. The painting may be warmed by the sun, or, with more care, by the fire.

Foreign Correspondence.

Paris, September 10, 1860.

A fortnight ago I left Paris for Tréport, with the intention of taking some sea baths. To tell the truth, although my enfeebled health required that invigorating treatment, I counted but little upon the effect of baths, which the season's persistent inclemency would necessarily render unfrequent. I founded more serious hopes upon the purity and freshness of the air, upon the bodily repose, and upon the setting free of the mind from its habitual occupations, and from those ideas which, besetting it at the same hours day after day, finish by wearying the brain. I was like one of your city merchants who, after the labours and all-absorbing preoccupations of the week, quits his office on Saturday, bidding business good-bye till the Monday morning. I penitently confess to having thought, with a certain pleasure, that for some few days I should hear no more of collodion, nitrate of silver, hyposulphite, camera, and stereoscope.

Tréport is a charming little port, seated at the foot of a cliff in our fertile Normandy—a town inhabited by two or three thousand fisherfolk, and visited in the bathing season by a few modest families, for whose tastes or purse the luxury of Dieppe and Boulogne would be ill suited. I had, therefore, much chance of finding there a calm which would be beneficial to body and mind, and I started in all confidence. The first person, however, that I saw on getting down from the carriage was a gentleman carrying a photographic apparatus, and whose costume and white hands led me to judge him an amateur. The next morning, at the entrance to the jetty, where I had gone at sunrise to enjoy the fine spectacle presented by the sea at that early hour, I found a camera with its objective pointed at the port, and seeming to bar my way. This time there were two operators, and their mode of proceeding showed them to be professional photographers. The day following, I met two others coming in from the environs with their baggage. It was enough to make one believe that all the photographers of the country had fixed, for their common rendezvous, upon this little out-of-the-way corner of France. But I was still more surprised when, on returning from an excursion into the country, I found in the very middle of the quay a booth, which seemed to have grown there by enchantment, and which was no other than the extemporised operating-room of one of those nomadic photographers of whom I spoke in a previous letter. Already the portraits of the best known bathing-men of the place were exposed to public view, together with the figures of a few soldiers picked up on the road, and a dozen or so of half-obliterated stereoscopic views. As I passed, a baby, mounted on a donkey, was having his likeness taken in the interior, the door being left open to excite the curiosity of the wondering natives; and, while the *artist* and his assistant were operating, two women were seated at a table, busy with needlework. When I left Tréport two days ago, the little tribe had not yet struck their tent; without doubt, business was going on prosperously. I know not whether the wandering disciple of Daguerre took many portraits; but I know that there was one which must have paid him well, for copies of it were in great demand. It was that of the chief of the master-bathers—a handsome fellow, with curly hair and light-coloured beard, whose lessons and protecting care were much sought after by the numerous and elegant *baigneuses.* Thus has photography invaded the whole land; and there is now-a-days no nook so obscure as to be without a rambling portrait-taker.

As I have confessed to you my selfish disappointment at finding in my retreat that which, on leaving Paris, I had wished to fly from for a few days, I must also avow that I was led to regret that there was not about me a still larger number of photographers, whether amateurs or professionals. It was on the 20th of August, for which day had been announced a solemn procession to the summit of the cliff, which, from its three hundred feet, looks down upon the little town, the surrounding country, and the outstretching sea. The object of the ceremony was the erection of a colossal cross, supporting an image of the Saviour two yards in height, which might be seen by the fishermen of the country in their little voyages, which rarely extend to more than three or four leagues from the coast. After a religious service at the Church of Tréport the procession set out. The little girls of the place, clothed in white, and bearing little blue banners, went first, led by Sisters of Charity; then came seamen bearing tapers, and then twelve master boatmen, who bore on a litter the image of Christ, in cast-iron, weighing more than four hundred pounds—a heavy burden for such a road. After them went the clergy of Tréport, whose numbers were swelled by all the *curés* and *vicaires* of the neighbouring localities, and then the numerous and peaceful crowd. They formed a striking spectacle as they slowly climbed up the steep and verdant slope of the cliff, and seemed as it were suspended 'twixt heaven and earth. When the summit had been reached, and the image of Christ, so laboriously brought up those heights, had been fastened to the cross, the appointed preacher, from that magnificent natural pulpit, amid the deepest silence, addressed an animated discourse to the multitude around him, who had quitted their homes in the adjacent villages to be present at the ceremony. The splendour of the place, from which could be scanned an immense horizon—the very simplicity of the scene, bringing to mind the primitive Christian days—together formed an admirable picture, which, in the open air, and with the motionless and attentive crowd, it would have been easy to seize; but unfortunately there was no photographer there to reproduce it.

On my return to Paris, I found but a few communications respecting the eclipse of the 18th of July. These show that in all parts photography was largely turned to account on that occasion; and the results reported prove that the art is now become an indispensable auxiliary to astronomy. ERNEST LACAN.

Correspondence.

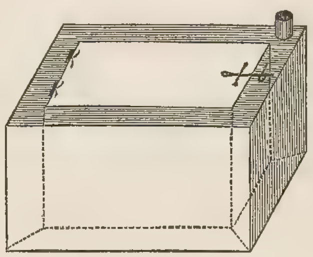
DRYING BOX.

To the Editor.

Sir,—I enclose a rough model of what I call the "Photographic Water Oven."



About two years ago it occurred to me that such a thing would be very useful to those who wrought the dry-plate process, and I applied to a photographic friend, who was a better draughtsman than I am, to make me a sketch of it, so that I might send it for insertion in your useful Journal; but he said that although it was good yet no one would go to the expense of getting one, so in consequence of that I did no more in the matter, although I have often thought it a pity such a thing was not adopted.

I think you will nearly understand by the model what the "oven" is like. If you fold up the inside part first, and stick the gum paper where you will see it should go, you will observe that it forms a box. Then fold the outside part, and it forms a box outside the other, with a space between for the *water*. The whole to be made of tin or brass. Of course, the inside box will have to be supported from the bottom of the outside one; on the top at the corner is the hole for putting the water in; and in the centre of the top there may be another hole, made with a conical rise, on which may be slipped a *worm*, and then would be got *pure* distilled water;—although it might not be much, still it could be depended on for particular work. The front and sides ought to project about an inch below the bottom to keep the smoke from the gas or lamp from coming up that way; and what will be an improvement on my plan will be to put ledges on the sides, such as Shepherd and Co. have on their little apparatus for plates that do not require to be kept so free from dust. The whole can be made to hang on the operating-room wall like a German clock, so that a gas branch can be turned in beneath it at pleasure, and one can receive light from it at the same time that it heats the water.

Now, sir, if you think the above worthy of a place in your Journal, and you will take the trouble to insert it, I shall feel happy in making a small return for the many hints I have received from others through the medium of the Journal, &c. It was by seeing how you appreciated Messrs. Shepherd and Co.'s plan that I thought perhaps some photographers might think more of my contrivance than my photographic friend above referred to.—I am, yours, &c.,

WM. BIRNIE.

ENLARGING.

To the Editor.

Sir,—Supposing a portrait taken with a half-plate lens were enlarged in the printing by means of a solar camera to what is called full-plate size, would there be any difference as to sharpness between that and one taken with a full-plate lens, and printed in the ordinary way? And would it take any longer to print in the solar camera than the ordinary one?

As I wish to take larger portraits, and have only a half-plate lens (Ross's), I wish to know, and shall feel obliged by an answer through your Journal.—I am, yours, &c.,

Aug. 28, 1860. A LADY PHOTOGRAPHER.

[Your note reached us too late for reply in our last. We perceive that you have also made the same inquiry of a contemporary; and though we have no wish to cause you any embarrassment, *our* reply you will find *diametrically opposed* to that you have already received.

It is impossible to enlarge a negative without some loss of definition, be it much or little; and we consider money spent on the solar camera just so much waste. For details of the subject we refer to our last volume, pp. 236, 253, &c.

You will obtain better results by taking a small negative and enlarging therefrom to some extent, than from a larger negative with more moderate increase of dimensions (at least that is our experience); but there is certainly more labour incurred by enlarging than by taking full size direct.—Ed.]

FAULTY PAPER.—PETSCHLER AND MANN'S DRY PROCESS.

To the Editor.

Sir,—I beg to return you my most sincere thanks for your replies to my former queries. I was not able to attend Mr. Hardwich's classes, as I had not time to remain sufficiently long in London. I have, however, been since trying what I could do without aid, and I think I have succeeded pretty fairly.

I have met with a difficulty which I cannot explain. The enclosed will show you what it is. The two stereographs I send you are on paper made by different makers. The red-toned one is made by Rive, and the other one by some Scotch maker—I forget his name. Both papers, however, print very well in the printing frame. Perhaps you will be kind enough to say which is the proper tone, and make any remarks on them, or on the negative from which they were printed, that you may think proper. I have been trying the modification of Taupenot's process, as described in your Journal of the 16th August. I have met with the greatest success. I have not given the plates sufficient time to know how long they will keep; but I do not see any reason to prevent them "keeping" to any extent of time. I shall be happy to forward you a correct copy of this village—I mean a stereo-print—if you think it worth your acceptance.—I am, yours, &c., A NOVICE.

[Your success is certainly very satisfactory, and gives promise of your becoming a good photographer. The specimens of paper are very faulty, being full of metallic spots. We recommend you to apply to Mr. Hughes, of Oxford Street, for some that he knows to be good. You must be careful, in sensitising your paper, that the surface of the silver solution is free from floating particles, otherwise they will produce little specks on the proof. The specks on the specimens you have sent, however, clearly arise from minute grains of some metallic substance in the pulp of the paper, as you may readily perceive on examination under the microscope. The reddish-toned print is not unpleasing for some subjects, but too warm for general purposes; the other is a little too grey, but not bad. The fault lies in the paper, which has too little chloride in it to enable you to get a vigorous print. We have very little fault to find with the negative: a rather longer exposure would have improved the foliage without spoiling the rest. Remember you should expose with reference to your *shadows*. You need have no fear of the "keeping" qualities of the plates. We shall be happy to receive the proffered print of "our village"—Ed.]

☞ **The Publisher, in reply to continual inquiries, begs to inform present or intending Subscribers to this JOURNAL that no difficulty exists to prevent its being received on the respective days of publication (viz., the 1st and 15th of each month) in any part of Great Britain and Ireland. It is printed in sufficient time to be despatched by the Publisher, Liverpool, or by the London Wholesale Agents, so as to reach the most distant Subscribers and Agents on the above days. Orders sent direct to the Publisher, accompanied by a remittance (if by post-office order, made payable to Henry Greenwood, 32, Castle Street, Liverpool), or to the London Wholesale Agents, Messrs. E. Marlborough and Co., 4, Ave Maria Lane, E.C., will receive immediate attention. Foreign Subscribers and Agents can also be supplied in the same manner by paying the additional postage charged by the Post Office. Orders given through Country Booksellers are carefully executed by Messrs. Marlborough and Co., as above, or by the Publisher, Liverpool.**

ANSWERS TO CORRESPONDENTS.

E. R.—You may do so with safety in the quarter indicated.

An Intending Amateur.—Mr. Thomas Ross, Featherstone Buildings, High Holborn.

J. F. R.—We cannot recommend you to purchase the apparatus you mention: it is, in our judgment, a mere toy.

Queechy.—The American views that you speak of are mostly very good; a few of them but indifferent, but only a few.

Scotus.—It is a delicate question to answer truthfully, yet inoffensively. We can safely say, "bide a wee bit," and you will be no loser.

Chas. Cooly.—We believe the quondam replies, relative to the class of pictures named, to have been all "bosh." We do not believe a word of it.

Anxious Artist.—We think, from their aspect, that they must be by Wilson, of Aberdeen; but we have only seen them in passing the establishment you name.

F. C.—1. Needless in the Fothergill process, but no disadvantage. 2. The process named is, in our opinion, a mistake. We recommend you to try Petschler's process.

One of Many.—It would be impossible for us to do as you wish, even if we were inclined. We only criticise such as are sent to us for that purpose. It would scarcely be fair, even if practicable, to do so unsolicited.

Wenham.—If the water be not clear, there is still a portion of chloride *in suspension*, and you lose a portion of the silver by throwing it away. Probably boiling the water in an earthenware vessel will cause precipitation to take place.

J. S. (Oxford).—You have omitted to add a few drops of solution of nitrate of silver to your developer. This is a *sine quâ non* for dry plates. Wet ones have already enough to form the picture, but on dry plates there is little or none left.

S. E. C.—We do not apprehend that there is any occasion to fear the light of a fire in the developing room. A *very* brilliant blaze might possibly affect a *very* sensitive plate, if held too near it; but that is a contingency not likely to arise.

Faulty Negative.—We do not perceive any reason why you should not paint out the blemishes from your negative: there is no fraud unless you attempt to conceal it. When you send in your picture, you can say "touched negative."

Goose.—Perhaps "some one else" might designate you by the name of another web-footed bird instead. Is that the reason why you make so bad a sitter? Just fancy *yourself* criticising *yourself* in the looking-glass, and then you will do very well.

Adolphus.—The first on your list of names decidedly. The last mentioned is very good for the price, but it is a "Jerusalem pony" to a racer as compared with the other. The gas stove will do very well, provided that you carry off the vitiated air by a tube into the chimney.

Jessie.—You had better begin by learning to print well: beg, borrow, or "otherwise acquire," a good negative to operate with, and carefully note the instructions for printing. By a little practice you will learn more of photography generally than by any other course of proceeding.

Erc.—Nos. 4 and 7 we have not seen; but the other five we have minutely examined, and find that each has some peculiar advantage for certain purposes. For our own use, when moving about from place to place, we should prefer No. 5 on your list. No. 1 is very good and roomy, but is heavy, and takes some time to put up, so that it is not so well adapted for *constant* change of place.

Samuel Evershed.—We can most certainly recommend the article about which you inquire. We have no influence in the commercial phase of photography, and, therefore, cannot help you to obtain the advantage mentioned. We are a little amused at your extra faith in our opinion "because you are a personal friend of our publishers'," who are gentlemen that we have never to our knowledge even seen, or had any direct communication with, as we have nothing to do with the "business" of the Journal.

J. S. Borwick.—We believe that the composition you mention is to be purchased, and that the artist resides at 168, New Bond Street. Collodion iodised with a cadmium salt will keep for a very considerable space of time without deterioration; most other kinds change more or less for the worse in a few weeks (sometimes days), gradually becoming more and more highly coloured. A partial restoration is effected by immersing therein a slip of pure silver or cadmium. Never *throw away* collodion: when utterly spoiled for any other purpose, it is capital for cleaning glass plates that have been previously used.

No Chemist.—Your developers will do very well. You are mistaken in supposing that no intensification occurs; the fact of your negative *turning red* proves that it does. To satisfy yourself proceed as you have been doing, only *intensify one-half* the plate, leaving the other half as it was after development with the iron solution; then print from the plate, and you will soon perceive the difference. You should fix with hyposulphite of soda, as the greater intensity produced by the organic matter of the pyrogallic developer is nearly destroyed by the use of cyanide of potassium as a fixing agent. A little dilute albumen (a few drops) added to your pyrogallic solution, when intensifying, will very materially increase the effect.

A. H. J.—1. You err in supposing that you should have *exactly* the same portion of the view in both halves of your stereograph. You may correctly take a quarter of an inch more on each side of the pencil lines that you have drawn, which will make half an inch difference in the whole. The reason for this is that you are to suppose you are regarding the subject *through* a rectangular aperture—a window, for instance, in which case (as you may demonstrate by trial) you will find, on closing each eye alternately, that the right eye sees a little more of the left side, and the left eye a little more of the right side of your subject. Your lenses are, however, rather too close together, and might be separated another half-inch apart, with advantage. Get your brass plate cut through between the lenses, and you can then separate them.—2. Add one grain of bromide of cadmium to your collodion, and you will find that the greens will come out better, but your exposure must be longer. The snowy effect is apt to arise *not* from *over exposure*, but under exposure and over development.—3. Good.—Cadmium.

⁂ "Government in Competition with Professional Photographers," No. II, with other articles, have been deferred from want of space.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 127, Vol. VII.—OCTOBER 1, 1860.

We verily believe that it would be quite worth the while of some of the larger enterprising railway companies, which endeavour to coax the money out of the pockets of a certain section of the public by offering what are designated as *tourists' tickets* at reduced rates, to establish in the waiting rooms some of those cleverly-constructed PEDESTAL STEREOSCOPES that are furnished with an almost unlimited number of stereoscopic slides, which can each be brought into view in succession by turning a small knob, the mechanism acting upon a similar principle to that of the Jacquard loom. Of course the object would be to exhibit stereoscopic views of the various interesting localities accessible by the line. This is a scheme which we have little doubt might be readily made to pay; for the probability is, that the railway companies might obtain the stereographs without charge for the consideration of the perperpetual advertisement thus afforded to the photographer producing the stereographs, who would of course stipulate for the privilege of appending conspicuously his own name and address. As there are few people now in such an uncivilised state as not to possess a stereoscope, while nearly all like to take away some record of the places associated in their memories with holiday trips and all sorts of pleasant reminiscences, the photographers would find their account, not only in bringing people to their own localities, but also in putting their goods before them in a prominent and memorable manner. We certainly started the idea half in joke; but, in sober seriousness, we do think it is one that might very profitably be carried out.

Of course it is to be expected that, in viewing a stereograph of a locality that has been visited by the spectator, he will most probably recognise it with readiness; and this is a pleasure that we have on many occasions experienced when criticising specimens that have been forwarded to us for the purpose. But we have recently also experienced the converse of this in a visit to Dovedale, in Derbyshire, where, though unaccompanied by any one acquainted with the spot, we were enabled to recognise with facility most of the remarkable points of interest along that very beautiful valley, simply from being familiar with Mr. Woodward's illustrations of them—a detailed notice of which appeared in these columns some time since. There are also many other places with which, not having visited, we are yet intimately acquainted, and have no moral doubt that we should be quite at home in; for have we not been introduced to them by Wilson, Rodger, Sedgfield, Ogle, and many others? Truly this same stereoscopic rendering of the many favourite haunts of pleasure seekers is one of the *institutions* of the present day, and a very pleasant one it is.

We find photographers are very strongly inclined to try whether it may not be possible to return with advantage to paper as a vehicle for negatives; but we regret to notice that with many of them, instead of attempting to substitute paper for glass, they are endeavouring to reduce the calotype process to its simplest expression. Although this may prove an advantage in one respect, we cannot be otherwise than conscious that, while the paper itself is made the recipient of the sensitive substances, all the evils that have led to the abandonment of paper for negatives cannot fail to be re-introduced, *e.g.*, granulation, absence of sufficient definition, spots from flaws in the fabric itself, &c.

One very curious circumstance has occurred in connexion with this subject. In the respective numbers of two of our contemporaries, which appeared on the same day as our last, we find a simplified calotype process, almost identical in all particulars, put forth both by Mr. Prichard, of Leamington, and Mr. Sutton, of Jersey—though the latter, by the way, does not admit that it is a calotype process at all: in this we think he errs, as the principle involved is precisely the same, the mere details of manipulation alone differing. In stating this, we are by no means decrying the improvement in the preparation of the paper—for such it is; but simply protesting against any possible improvement, where the image is in the paper, being sufficient to cause the abandonment of glass as a support to the sensitive film. We do not suppose that there has been any direct communication between the gentlemen named upon the subject in question; for, though their operations are very closely alike, there is a sufficient variation both of quantities and method of application to show that it is simply another case of experiments in parallel directions. The object of both is to prepare a sensitive calotype paper by continuous operations, instead of, as formerly, obtaining first a coating of so-called insensitive iodide of silver, and subsequently rendering it sensitive by the application of aceto-nitrate of silver a short time before exposure. We have no doubt that the plan proposed is a considerable saving of trouble, and that the results are at least equally good; but, for those photographers who are content with calotype negatives, we would suggest the trial of a further slight modification, whereby valuable time might be saved in getting a few sheets ready for the camera, especially when away from home. Our idea is to endeavour to take greater advantage of Mr. Petschler's principle than has yet been done in its application to paper, and proceed as follows:—

Coat the paper on both sides with a measured quantity of solution of an alkaline iodide, the application of which may be either by means of a very shallow glass dish, as advised by Mr. Sutton, or by the glass rod, as directed by Mr. Prichard. In either case the object is to apply a given dose, neither more or less, to the sheet of paper. As regards the strength of the solution, we incline more towards Mr. Sutton's, namely, thirty grains to the ounce of water, than to Mr. Prichard's, who only directs six grains; but probably somewhere between the two would be best—say twenty grains. After soaking for a few minutes, the paper to be pressed between blotting-paper, and while still damp treated on both sides with a measured quantity of aceto-nitrate of silver, of say thirty grains of nitrate of silver to the ounce of water, with from ten to twenty minims of acetic acid, according to weather, &c. The paper is again pressed

between blotting-paper; and thus far we have proceeded precisely as suggested by both operators, who then wash the paper in water, to remove superfluous nitrate of silver, and then put it in the dark slide ready for exposure. But if, instead of plain water, we substitute a weak solution of chloride of ammonium, or similar substance—say one grain to the ounce of water—we could then dry our paper, which ought to be insensitive to light, or nearly so, but which could be readily rendered fit for exposure by merely soaking in water just before being required to be placed in the dark frame, which might be done, as in the cases suggested, while still wet. Of course, this would be nothing more or less than the application of Mr. Petschler's principle to the calotype process. We have not tried the experiment proposed: want of time quite precludes our so doing at present; but we throw out the hint for the benefit of those whom it may concern.

It is with sincere regret that we have to record the decease of one of our veteran photographers, in the person of Mr. Peter W. Fry, until very lately a member of the Council of the Photographic Society, and one of its original promoters. He was formerly a member of the Photographic Club, and one of the earliest followers of the calotype process; and we have, on several occasions, listened to his amusing account of the very primitive and awkward kind of camera with which the earlier photographers had to be content. He was very active in introducing Mr. Archer's discovery of the collodion process, and materially assisted that gentleman in bringing it to the needful state of perfection. We cannot forbear relating an anecdote, which we had from his own lips, of an incident that happened to him, and which caused him no little feeling of embarrassment. Being in Italy, with some members of his family, he had taken a photographic copy of a work of art with which he was struck, and subsequently noticed a student (a foreigner) who was employed for several consecutive days in copying the same subject by hand. Thinking that a copy of the photograph might be of service to the poor student, he, with his usual kindness of heart, printed one for him, and made the offering to him while he was at work on the following morning. The student received the gift with many thanks, inspected it carefully, comparing it with the original: he looked at his own work with evident disgust afterwards, and, snatching it from the easel, *he dashed it violently across his knee, thus rending it into tatters*, and destroying in one instant a week's work. Mr. Fry used to declare that he never remembered to have felt more awkward than upon that occasion.

Mr. Fry's loss will be deplored by a large circle of friends, including many both in the artistic and scientific *coteries*. He was a pleasant companion, a kind-hearted friend, and a most enthusiastic photographer.

OBSERVATIONS ON ALBUMENISED PAPER AND ALKALINE GOLD TONING.

By C. Jabez Hughes.

No. II.

The Plain Paper.—In the former article I endeavoured to show that albumenised prints depended for their character and tone mainly upon the original plain paper. I pointed out that, although there are English, French, and German papers at command, the two latter are principally used, and I promised to discuss in detail their particulars. In resuming, I wish it to be understood that my remarks apply only to their fitness for albumen prints.

Plain paper may be spoken of as composed of two distinct substances, *pulp* and *size*. The pulp—chemically speaking *cellulose*—when examined under the microscope is seen to be a mass of fibres interlacing in every direction. In this form—blotting-paper is a good example—from its soft, spongy, absorbent nature, it is obviously unfitted for printing upon; but when the "sizing" is added, binding together and cementing this loose vegetable felt, the material then properly becomes paper. If this distinction be borne in mind, that paper is formed of "pulp" and "size," and that each of these is subject to defects, its nature can be more readily examined, for it may happen that a given paper may be good in one respect and bad in another.

The "pulp" is derived in all countries from the same sources—cotton and linen rags—and it probably does not vary much in its nature. I do not conceive it plays any important part in forming the photographic image. I consider it acts only mechanically as supporting the albumen film, and retaining the sensitive solutions within its fibres.

The "sizing," however, performs a chemical as well as a mechanical part; for not only does it cement the fibres together, but it unites with the silver and gold salts, and materially determines the nature of the picture obtained.

Although the paper makers of England, France, and Germany, are fully agreed that linen and cotton rags are the right materials for the "pulp," they are by no means unanimous as to the proper composition of the "sizing." In our own country gelatine is used; in Germany, starch; while the French are supposed to employ a mixture of starch and resin; but it really is not exactly known what is used, for the manufacturers do not allow their trade mysteries to be penetrated. It is sufficient that, while there is not much difference in the pulp, the sizings vary very much indeed, and communicate their character to the paper.

In judging of the pulp the paper must be examined by holding it to the light and looking through: a good paper will show a uniform texture, with very few spots and irregularities. Estimated in this manner, the English papers are generally very good, their principal faults being iron spots; the German or Saxe papers are also very good, scarcely so uniform in their texture as the English, having a mottled appearance, which, however, never shows in printing; while the French papers, especially those known as "Rive," are found to be extremely defective. The whole paper has more or less a honeycombed, speckled appearance, numerous holes, and no end of transparent and opaque spots. Canson used to make paper comparatively free from these faults; but he does not now, his new make being about the very worst in use. A great number of the defects seen in these Rive papers, however, do not show in printing, but then a great many do; and any photographer who uses this paper must be very lenient and patient, for there is no possibility of obtaining it without these objectionable peculiarities.

Perhaps this will be the proper place to correct a very prevalent error among photographers, who imagine that "Rive" is the name of a maker of paper like Canson. The fact is, Rive is the name of a small town in France, where, water-power being abundant, there are a few paper mills, the largest of which is "Blanchet, Frères and Kleber's." These makers sometimes have their initials in the water-mark, "B. F. K." In one batch the word "Rive" will also be there, in the next absent. Sometimes only the word "Rive" will be found, and occasionally only a few sheets in a ream have any water-mark. I mention this in explanation, for I have known photographers declare the paper to be entirely different, though coming from the same mill, because the customary water-mark was absent. "Rive" means therefore, like "Saxe," not a maker's name, but a small district producing paper of a particular character.

In the French papers the "size" employed, whatever it be, gives them an extraordinary hardness. The fibres are cemented together very closely, so that the surface is very hard and fine. When this paper is laid on albumen it seems of a repellent nature, is inclined to curl, and finally, when taken off and dried, retains the albumen almost entirely on the surface, giving the highest glaze of any papers. Those persons who wish the very highest gloss must always ask for Rive, for no other paper can be had, all other things being equal, which so readily takes the highest gloss; but they must remember that there exists a greater quantity of spots and marks, as already mentioned.

In the German or Saxe paper the sizing is not nearly so hard as in the Rive. The surface therefore is not so fine, and, when albumenised, the albumen seems to sink into the paper. It never receives so high a gloss as the Rive. On the other hand, those defects so common in Rive are almost absent in the Saxe. The greatest care appears to be taken in the preparation of the pulp, and very few defects are to be found in it.

Judged by the standard of the other two papers, the English sizing seems very indifferent. The surface of the paper is never so fine as the French, and seldom quite so good as the German. The albumen sinks into it more even than in the German, and when immersed in the solutions this paper more than any other gets woolly and soft, thickens, and becomes porous. The peculiarities

spoken of are quite independent of the hot pressing or glazing, and is entirely due to the sizing.

The above papers all act differently in toning. The English ones print red in the pressure frame, and tone very reluctantly, adhering very much to some shade of reddish brown. They can be got to deeper colours, but not so easily. The Saxe papers print a dark colour, and are readily toned, passing quickly from the red tint they assume when they are washed. There are no papers, however, which have given so much trouble in toning by the alkaline gold as this Saxe. There seems a tendency with it, in many persons hands, to get a disagreeable, inky, mealy, granulated appearance. There is no real reason why this paper should give these unpleasant tones, and those who have experience know how to avoid them; but as the matter will be more fully entered into when "toning" is considered, the subject will now be waived.

The highly-glazed Rive paper is difficult to tone; and with a gold and hypo. bath it is almost impossible to get a deep purple black without the whites being yellow; but with the alkaline gold it can easily be done. To my mind the richest of all tones are obtained on this paper. The gold seems to enter into union with the albumen, and a singularly rich colour can be produced. To all who are troubled with grey and mealy blacks with the Saxe paper I recommend a trial of the highest-glazed Rive, and I think they will get rid of their troubles.

In forming a comparison between the three kinds of papers, it is seen that if that paper be judged to be the best that gives the highest glaze and allows the most perfect surface definition, the Rive stands the first; if the absence from defects and readiness of toning be the standard, then the Saxe is the highest. Thus, while something may be said in favour of both French and German papers, the English remains behindhand, for it has not the fine surface of the one or the rapid toning properties of the other; but while, unfortunately, it has neither of the merits of its rivals, it in some degree possesses both their defects—the soft porosity of the Saxe and the metal spots and reluctant toning of the Rive. Can it, therefore, be wondered at that English paper is not in general use?

The subject of albumenising is far too important to be commenced here, and must be deferred till next number.

THE PHOTOGRAPHER'S TRIPOD.

By George Shadbolt.

[Read at the Ordinary Meeting of the North London Photographic Association, 26th September, 1860.]

The tripod, in its connexion with photography, may be regarded somewhat in the same light as the bellows-blower in a performance on the organ, each being indispensable to the attainment of the respective ends in view, and neither entitled to any portion of the honour acquired in either case. There is an anecdote on record of an organ-blower who vindicated his own dignity by ceasing to blow in the middle of the finest part of the performance, thus bringing it to an abrupt termination. The indignant organist shouted out, "Blow, you rascal!—why don't you blow?" "Because you said last time the WE did not play, but only YOURSELF,—now *why don't* YOU *play?*"

I propose this evening to vindicate the dignity of the tripod; but I hope to show you that it really has some cause for consideration, and that a portion at least of photographic failures are due to a "weakness of constitution" in this assistant to the landscape photographer, which holds a very subordinate rank. It may be asked why, if a robust constitution be desirable for this useful servant, one is not always engaged with that qualification? The reply is simple: because, as a rule, it involves an extra-robust constitution in the operator himself in order to contend with the additional weight required, which extra vigour cannot so easily be obtained when desired; and therefore, in order to accommodate the contending interests, the vigour of the tripod is too often shamefully sacrificed to the weakness of the operator.

To drop jesting, however, I may remark that the numerous attempts made to produce a portable tripod indisputably indicate the demand existing for an efficient article of the kind; and, as every experienced operator knows full well the great importance of stability in the very foundation upon which the camera rests, it is not surprising that folding tripods bear but an indifferent reputation, and are tolerated rather as unavoidable evils under certain circumstances than adopted with that confidence which a "strict attention to their duties" would ensure.

Before describing an arrangement that I have contrived for my own use, it may be as well to consider what are the desiderata in a tripod? In my opinion the are—

1. Rigidity.
2. A height of not less tha five feet; but six preferable.
3. Portability and lightness.

Rigidity being the most important, must be the first consideration. The height of the lens should not be less than that of the eye when the spectator is standing; but generally it may be somewhat higher with advantage, not only as conducing to a more imposing view of general landscape subjects, but frequently allowing the operator to avoid a foreground of dead wall, or the unpicturesque arrowheads of an iron railing. The consequent lengths of the "legs" is therefore antagonistic to the quality of firmness, which is still further aggravated by any attempt to increase the portability by making the "legs" each length in two pieces; which, however, it is absolutely essential to do with so great a length as six feet, if we do not wish to be put to no end of inconvenience in moving from place to place, especially when proceeding by rail.

Having tested several kinds of portable tripods, and found that in use there was always a deficiency in rigidity, especially when the lower portion of each "leg" consists of a single piece, I determined to attempt a solution of the problem myself, about two years back. The result I am now about to lay before you.

I may mention that I abstained from so doing at an earlier date, as I met with a portable tripod, constructed by one of our most intelligent dealers in apparatus, and which at first view appeared to me to accomplish all that I had attempted with some other conveniences. Subsequent experience has, however, proved to me that, except for stereoscopic or other small cameras, my own form of tripod is decidedly the better of the two. The principle involved in its construction is a close adherence to as complete a system of triangulation as possible. Some of the details may be varied to meet particular cases, but the principle of triangulation must never be lost sight of.

Having completed the theoretical construction of my tripod, I made such variations in the details as would enable me to convert an already existing one into the portable form, and the result is the one I now lay before you. Although an unusually long one, by folding it in halves the length is brought within very convenient limits for being carried about; and though each "leg" consists of four pieces, these are so connected as never to become detached the one from the other, and when put up for use, the different bearings are contrived with a view to afford mutual support, and, as it were, "lock" into one another. The annexed diagrams will explain the construction more perfectly.

FIG. 1.

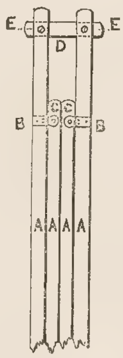


FIG. 2.

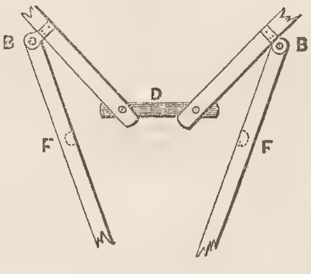

Fig. 1 shows the extremities of the four pieces forming one "leg" when folded—A A A A being rectangular pieces of mahogany $1\frac{1}{4}$ by $\frac{5}{8}$ of an inch in dimensions, the thinnest edge being towards the spectator; B B are two hinges, formed by straps of brass or iron clamped round the outer pieces, and turning on pins at C, so as to allow the outer pieces to be turned quite over, as in fig. 5; D is a thin slip of metal let into slits at the end of the wood, as shown at *fig.* 4, and fastened by pins or screws passing through at E. To set up the tripod, the outer pieces are bent upwards, as in *fig.* 2, until they occupy positions as in *figs* 3 and 5. The outer ends of the slip of metal D fall into mortices at F, *fig.* 3, and thus the two portions of each side of the "leg" are firmly connected by two bearings, viz., at B and at F, in such a direction as to present most resistance to the strain.

FIG. 3.

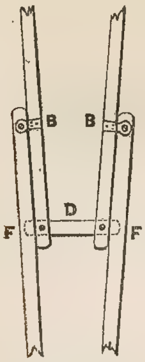

FIG. 4.

FIG. 5.

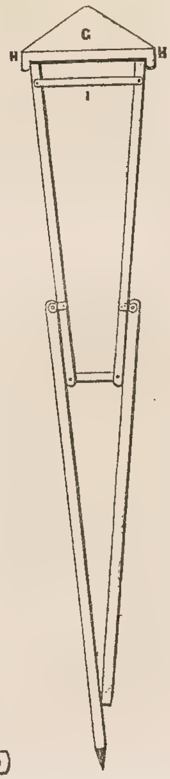

FIG. 6.

A triangular wooden or metal top G, *fig.* 5, is furnished at each angle with pins at H, on to which the ends of the leg-sides, furnished with brass sockets, are "sprung" by slightly squeezing them together; and they are firmly retained in this position by the slip of metal I, an enlarged view of which is shown in *fig.* 6. It is attached to the "leg" by a screw through the circular hole at K, around which it has motion; and on the opposite side of the leg, at a proper distance, is another screw, over the head of which the hole in the slip of metal will pass, and is kept rigidly in place by its falling so as to let the narrower part of the slit embrace the screw with the head of it projecting.

This arrangement is intended merely to save time in setting up the tripod, as I am not sure but that I personally prefer the arrangement of the tripod before you in this particular, in which a screw passes quite through the wooden head, and renders it extremely firm and rigid; but it certainly takes a little more time in setting up.

I can, from practical experience, testify to the efficiency of this tripod for cameras up to a size fit for pictures ten inches by eight inches; and I see no reason why, with a slight increase in the size of the top, it should not be adapted for cameras of almost any size. At any rate, such as it is, it is free to any manufacturer to make this tripod, if he be so inclined.

ON FIXING POSITIVE PROOFS.

By MM. DAVANNE and GIRARD.

(*Continued from page* 267.)

IV. *Number of proofs that can be fixed in the same bath.*—If in a similar solution of hyposulphite of soda we fix a sufficient number of proofs to effect its saturation, the time of fixing, which we have estimated at ten minutes, becomes increased as the point of saturation is approached; but prudence requires that we should only place in the same bath the quantity of salts of silver far below that required to saturate it. Now, the point of saturation of 100 parts of hyposulphite of soda is 38 of chloride of silver (or its equivalent), which is equal to about eight or nine large sheets, 17 by 22, if they have not undergone the first washing, and double that number if we only take this precaution. In practice, from excess of prudence, perhaps, we should not venture to exceed four large sheets, 17 by 22.

We prepared sixteen quarter sheets, and fixed sixteen proofs (10 by 8), in a solution of 100 parts of hyposulphite of soda in 500 parts of water (solution of 20 per cent.). The proofs were first washed in a bath of bicarbonate of soda, then two by two in hyposulphite, where they remained only ten minutes. After being washed and dried, we satisfied ourselves that the whites of the first and last were perfectly pure, and that the two proofs appeared exactly alike. The solution of hyposulphite of soda was filtered after this fixing to remove a slight deposit of carbonate of lime, produced by a little bicarbonate of soda: it had a slightly yellow tint, indicating the commencement of decomposition, arising without doubt (notwithstanding every pains that could be taken) at the moment when the hyposulphite of soda, penetrating the paper, came in contact with an excess of salts of silver. Therefore the bath that has served for one operation should never be employed further, but mixed with the residues.

We may then affirm that 100 parts of hyposulphite of soda, dissolved in 500 parts of water, will suffice to fix successively and continuously four whole sheets, of the value of forty sheets to the kilo (36 ounces), even when we omit the first washing in pure water, in which we persist in from the moment that the nitrate of silver is transformed into an insoluble salt.*

V. *Washing the proofs.* — We often fall into great error with regard to washing fixed proofs; and whilst some photographers, seeing the proofs are faded, pretend that this fading is due to hyposulphite of soda remaining in the texture of the paper, and propose, therefore, that the washing be prolonged from twenty-four to twenty-eight hours,—others, who see good proofs fade and turn yellow by a prolonged immersion in water, assume, on the contrary, that this washing injures the proofs in purity and brilliancy—that the impurities of common water are destructive to them—that we must consequently operate quickly, and perhaps with distilled water.

The experiments we have made simplify greatly this question. It enables us to explain the cause of these exaggerations in two ways, and to show, in practice, a rational and easy method of washing.

Under ordinary circumstances it is rarely that the proofs fade in consequence of the hyposulphite of soda remaining in the texture of the paper; and when this cause of fading manifests itself, it appears in round yellow spots, which destroy the picture by their spreading. This alteration is produced in a very short time—in a few weeks, frequently in a few days, after fixing. But when the picture is destroyed gradually, and turns yellow in an indefinite space of time, according to the dryness of the atmosphere in which it is placed, it is due to fixing in hyposulphite of soda, and on the appearance of decomposition; and it is in this case that prolonged washing only hastens this destruction.

We can affirm, on the other hand, that a long immersion in ordinary water does not injure the proofs; for we have taken proofs, cut them in half, when one half has been washed three hours and the other forty-eight hours, and there was no difference.

Experience proves that we must not attribute an injurious influence to the quality of the water at the moment that ordinary water is stirred; for we have never found the slightest difference between one half of a proof washed in river water during three hours and the other half having remained forty-eight hours in very hard water, to which was added sufficient chloride of sodium to give it a very salt taste: in this case the whites were slightly tinted. An immersion of twenty-four hours in water might influence an injurious action on the pulp of paper, but it would not injure the proof as much as if fixed in a sulphurous bath: in this case the water acts in some few hours, as humidity of the atmosphere acts

* We have also attempted to simplify the fixing. In the course of our researches, we have proved that if we add bicarbonate of soda directly into a solution of hyposulphite of soda, the nitric acid acts upon the bicarbonate before it decomposes the hyposulphite. On the other hand, and in another series of researches, we have ascertained that the presence of chloride of sodium greatly retards the decomposition of the argentifous hyposulphite of soda, even in the presence of light. From this very simple idea we make a bath in the following manner:—

Water	500 grains.	Filter the solution.
Bicarbonate of soda	10 „	
Common salt	25 „	
Hyposulphite of soda	100 „	

It will be preferable to make this solution beforehand, and to filter it at the instant it is used, to separate the precipitate of carbonate of lime, which is not formed quickly. In the quantity of bath above indicated we have passed sixteen proofs, 8½ by 10½, in removing them from the printing frame; but we have not found the same result as by employing two separate baths. The tone of the proof is not so strong as at the commencement of the fixing. The bath filtered immediately had evidently the same tint as the first. Always after forty-eight hours of repose it will acquire a much deeper tint than the bath of simple hyposulphite. It has then a greater tendency to decompose: its employment is doubtful, and must only be sanctioned by practice. It is probable that this difference is due to the action of carbonic acid set free in the bath.

in a much slower manner, and hastens the fading, which would not have been apparent for a length of time.

The washing therefore can be very simply done if the proofs have been well fixed. An excess is not to be condemned; but it is useless, and should be confined to washing out the hyposulphite of soda.

In general we should use dishes about four inches in depth, using a large quantity of water, which should be renewed every half hour, removing each proof one after the other. After the sixth we may be sure of a complete washing; but we may assure ourselves that it is completed by a very simple method, first used by M. Bayard. All photographers have a test of exquisite sensibility for hyposulphate of soda: this is nitrate of silver.

If to water containing five-millionths of its weight of hyposulphite of soda a crystal of nitrate of silver be added, the characteristic yellow tint of sulphide of silver will be shown.

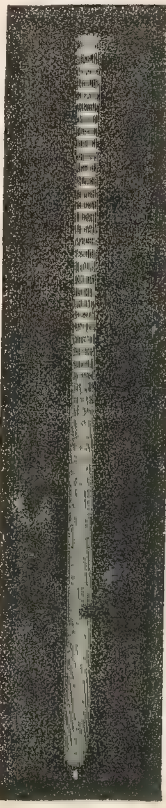
The most convenient way of employing this test is to lift a proof out of the bath when we think the washing finished, and to allow a few of the last drops that drain from it to fall into a white porcelain basin, and to throw into it, without stirring, a fragment of nitrate of silver about the size of a pin's head. If the yellow colour does not appear instantly at the bottom of the basin, or if it is not very apparent, it will bear another washing as a further precaution: if, however, the colour changes rapidly from red then to black, it will require two or three more washings. Independently of toning, which does not at the present moment demand our attention, we think that hyposulphite of soda, employed as now recommended, will not entail risk as to the stability of the prints, and that they will be in a condition to keep for any length of time if protected from atmospheric influences or exhalations which tend to attack the silver.

ON THE ACTINISM OF ELECTRICAL VACUUM TUBES.

By Professor W. B. Rogers.

[Being an extract from a letter to Mr. Gassiot, read before Section A, at the Oxford Meeting of the British Association for the Advancement of Science.]

I send you, by my brother, a printed abstract of remarks made some months ago on the phenomenon of the vacuum tubes, and a hypothesis as to the condition and cause of the stratifications.

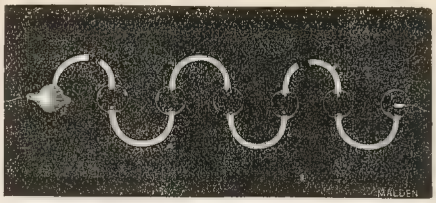


You will see that, with the aid of Mr. Ritchie and our skilful photographer, Mr. Black, I have been experimenting on the actinism of these electrical discharges.

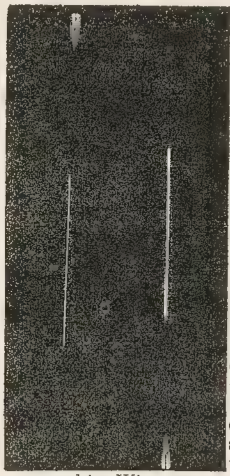
In some more recent trials I have obtained beautiful photographs of the stratification, of which I send you a specimen. The tube, as you will see, is a straight one, of uniform calibre. It is about fifteen inches long, by three-quarters inch diameter, and is marked by Geissler as containing phos. hydrogen. As you have perhaps observed, it gives the strata with extraordinary distinctness; and after the action has been continued a little while, the strata near the blank end *arrange themselves in pairs, consisting each of a bluish and a more reddish layer*, separated by a blank interval from the next, as seen very plainly in the photograph.

By a steady, rapid motion of the ratchet-wheel of Mr. Ritchie's coil, it was easy to keep the strata almost perfectly stationary. The picture was obtained with eighteen turns of the wheel, each giving twelve sparks. With six turns a tolerably clear picture was secured.

You see that the unilluminated space at one end made no impression, and that the intervals between the strata are also as devoid of actinic as they are of luminous rays.



The picture of the *winding tube*, with bulbs, shows how *superior* is the actinism of the faint *blue* light of the negative end compared with the brighter and less refrangible rays of the opposite bulb.



The third photograph was produced by the two slender Geissler tubes, containing respectively N and CO_2. The former was placed below the latter as they were presented before the camera, and the current was sent through them in succession. To the eye the intense whitest light of the CO_2 tube was more dazzling than the crimson colouring of the other. Yet you will observe the picture made by the latter is far the stronger of the two, as indeed might have been expected from its more refrangible illumination.

This photograph was produced with half a turn of the wheel, that is, six successive flashes of the light. I am unable to state the aggregate time of exposure to the rays, as I have not yet ascertained the duration of a flash. This I hope, with Mr. Ritchie's aid, to accomplish at an early day. But if we assume the time to be as much as tenfold the duration of the electric spark, as measured by Wheatstone, we should have less than $\frac{1}{20,000}$th of a second for the entire time which the light required for producing this intensely clear picture. I believe that a single flash would suffice, but I have not yet made the trial.

CELESTIAL AND INSTANTANEOUS PHOTOGRAPHY.

By Warren De la Rue, Esq., F.R.S., F.R.A.S., &c.

(Continued from page 272.)

Degree of Perfection hitherto attained in Lunar Photography.

In my own telescope, the picture of the moon is only about $1\frac{1}{10}$ in. in diameter; it might be suggested that the image could be enlarged by means of a combination of lenses before reaching the sensitised plate, but this would have the effect of prolonging the time of exposure, and moreover introduce the disadvantages of the refracting telescope, and the result would not be so good; for even if the moon's motion in declination were followed automatically, still the outstanding atmospheric disturbances before alluded to would remain.* Indeed, if the aperture of the telescope could be, considerably increased in relation to its focal length, much finer pictures would be procured, because the time of exposure would be shortened. In practice it has been found preferable not to magnify the focal image, but to take enlarged positive copies on glass direct from the original negative, by means of an enlarging camera, and in this way the impressions, 8 inches in diameter, exhibited at the meeting were produced.

In making positive copies, some of the more minute details are, unfortunately, always lost, for no means exist by which enlarged positive copies can be produced showing all the treasures of the original negative; a perfect enlarging lens being still a desideratum.† As an instance may be cited the streak in the lunar disc which Mr. James Nasmyth has called "the railroad," indicated in

* Monthly Notices of the Roy. Ast. Soc., vol. xviii., p. 17.

† Since the above was written, the author has been informed by Mr. Dallmeyer (son-in-law of the late Mr. Andrew Ross) that he has brought his investigations on this subject to a successful termination, and that he has just produced enlarging and diminishing lenses which copy without any sensible distortion or dispersion.

Beer and Mädler's map as a straight line to the east of the cratur Thebit, between latitude 19° and 23° south, and between longitude 7° and 9° east. In the photograph it is shown to be a crack in the lunar crust with an irregular outline, and the eastern edge is perceived to be depressed below the western, which forms a perpendicular cliff. This, although sharply defined in the negative, is frequently lost in positive copies. For the examination and micrometrical measurement of the minuter details which celestial photography is capable of furnishing, recourse must still be had to the original negative.

Notwithstanding the disturbances which arise from the atmosphere, minute irregularities in the driving-clock, and the want of means for following the moon's motion in declination, I have obtained pictures of the moon that bear examination with the three-inch object-glass of a compound microscope magnifying about 16⅔ times, and which show with good definition details occupying a space less than two seconds in each dimension. Two seconds are equal to about $\frac{1}{800}$th of an inch on the collodion plate in the focus of my telescope, and in the finest photographs, details occupying less than $\frac{1}{1000}$th of an inch are discernible with the three-inch object-glass; hence much valuable work has already been accomplished. A second on the lunar surface at the moon's mean distance being about one mile (1·149 mile), it will be evident that selenological disturbances, extending over two or three miles, would not escape detection, if such occur, provided photographs continue to be taken for a sufficiently long period.

Lunar Phenomena recorded by Photography.

Full Moon.—Variations of Apparent Diameter.—By the delineation of our satellite, photography brings out palpably several phenomena which, although well known, are not always present to the mind; for example, about every 29 days it is stated that there is a full moon, but we see by the photographic picture that there never is a full moon visible to us, except just before or just after a lunar eclipse, or at all events except when the sun, earth, and moon are very nearly in the same plane; at all other periods of the full moon we are unfavourably situated for seeing the whole of the illuminated hemisphere. Moreover, the different apparent diameter of the moon at various times, dependent on her distance from the earth, comes out in unmistakeable prominence in a collection of photographs; for the pictures taken with my reflector vary in diameter from one inch to one inch and nearly two-tenths (1·0053 inch to 1·1718 inch, being at the moon's mean distance 1·0137 inch).

When positive enlarged copies are made, it is easy to obtain all the pictures of exactly the same dimensions by the adjustment of the distance of the negative to be copied from the lens of the camera; and my enlarging camera is furnished with screws to facilitate the adjustment of the distance of the object to be copied, and also that of the focussing screen.

Libration.—We are familiar with the terms "diurnal libration," and libration in "latitude" and "longitude," yet it is difficult to realise the great amount of disturbance in the aspect of the moon's disc, and the direction of the displacement from the mean position which these several causes produce unless aided by photography, when we see them palpably before us.

The diurnal or parallactic libration never exceeds 1° 1′·5; the direction of the displacement in the markings on the lunar disc which it produces is variable, and is dependent partly on the position of the observer.

The poles of the moon at the epoch of mean libration are situated in the periphery, and the equator and all parallels of latitude are straight lines; the circles of longitude being more or less open ellipses, varying from a straight line in the centre to a circle at the periphery. This occurs when our satellite is either in perigee or apogee (when the libration in longitude is at a minimum), and she is also situated in one of the nodes of her orbit (when the libration in latitude vanishes): the nodes, apsides, and moon would, under these circumstances, be in the same line.

Libration in longitude merely causes a change of place in the various circles of longitude, which still continue to be more or less open ellipses; the parallels of latitude straight lines.

Those lunar craters, however, situated on the central meridian at the epoch of mean libration, would be on a straight line, but, at the periods of maximum eastern or western libration, they would be seen arranged on a semi-ellipse, whose conjugate diameter is 0·1377, the moon's diameter being unity. Therefore a point at the centre of the moon's equator becomes shifted by the sum of the librations to the east and to the west to the extent of more than ⅐th of the moon's diameter, namely, 0·0688 to the east, and the same quantity to the west of the mean position. On account of perspective, the effect of libration in longitude is much less apparent on the eastern and western peripheral meridians, which shift towards the centre by a quantity equal only to $\frac{1}{210}$th of the moon's diameter (0·0048).

The equator and its parallels, which at the period of mean libration in latitude were straight lines, become more or less open ellipses under other circumstances; the ratio between the conjugate and transverse axes of all the parallels being constant for a given inclination of the lunar axis. At a maximum libration in latitude the equator becomes an ellipse, whose conjugate axis is 0·1181; the transverse axis being equal to the diameter of the moon considered as unity: so that a point in the centre of the equator is shifted 0·059 of the diameter to the north or to the south by a maximum northern or southern libration, and will move by the sum of these librations to an apparent extent of ⅛th of the diameter of the lunar disc. The apparent motion of the north and south poles towards the centre is on account of perspective only $\frac{1}{280}$th of the diameter (0·0035).

Libration in latitude also causes a change in the ellipses which delineate the meridians, causing an inclination of their axes to the line joining the poles, and also a change in the ratios of their transverse to their conjugate axes. For example, the meridian distant 7° 55′ from the centre (this being the position of central meridian at a maximum libration in longitude) would have its transverse axis inclined 0° 56′·3 to the pole, the conjugate axis being no longer 0·1377 but 0·1368 of the transverse. The peripheral meridians would no longer be semi-circles, but semi-ellipses, whose conjugate diameter is equal to 0·9965, and whose transverse diameter is inclined 90° to the pole.

(*To be continued.*)

PHOTOGRAPHY A CHAMELEON.

"When next you speak of what you view,
Think others see as well as you;
Nor wonder if you find that none
Prefer your eyesight to his own."

A FRIEND of ours has set up an image which, at the sound of his own music, he commands all the faithful to fall down and worship. There is no fiery furnace, it is true, held *in terrorem* over the misdemeanants; but one does not like to be charged with thoughtless extravagance, especially by one who confesses his helm has been turned the same way as ours. He sings the glory and praise of the early photographers, and forgets the exceeding merits of the new.

We much question whether Daguerre himself, could he walk down a London street now-a-days, would have much to say against even the collodion positives, of which our friend is so deprecatory. Of course there are grim, ghastly, ghoul-like portraits perpetuated in this way; but who prefers a daguerreotype portrait now to a good one on collodion? Besides, it is almost "Hobson's choice" with the former: the operator is deterred by the cost from trying again, if you object to the first. In vain do you or your friends find fault. The nose, that Roman of which you are so proud; those whiskers, which excite your vanity; those eyes, whose penetration you make so much of;—the first is too snub, the second resemble the foliage on a windy day, the third are evidently trying to take in both ends of the room! There they all are—irremediable! You pay your money, but you are not allowed the benefit of a choice; whereas collodion is so cheap that the artist must be a niggard indeed who does not himself find fault, and say we can do better than that, and forthwith tries again. It was a labour, indeed, sitting in the old time for one's portrait; now you have half-a-dozen for *cartés de visite* taken at once.

Daguerreotype had, and has, advantages. The art was founded by its experimenters. Watt elaborated the steam-engine from a teakettle; and similar inventions, now so essential and complex, have had a like humble origin, for which they deserve the greater praise. We think the gentleman who overhauled his portfolio, and concluded that all was vanity and vexation of spirit, drew most probably a just inference; but who was to blame but himself? If anybody is to be hung, who must it be? Not the inventor of collodion, and the scores of ingenious contrivances and processes springing from it. We know no one who has tried more things in this way than the editor of the *Photo. Quarterly* himself, and now he wants us to fall back on—what? Daguerreotype! with its glaring

reversed results, which certainly do fade and often disappear; though, like most things, they can, with care, be preserved a long time, and can even be re-developed, and on paper. Paper indeed! Does any one remember direct positives on paper? What wonders those were! A large discount had in those days to be allowed for failures, so large as almost entirely to deter amateurs from the art; and, if they ventured on the task, soon to disgust them.

Some of our Manchester friends used to practise calotype, but it seems entirely abandoned now. Some of them are now at turpentine waxed paper, and we know not what complications these enthusiasts may venture on next; but the majority use some dry process on glass. We have some of Mr. W. Newton's calotypes before us, and one of Mr. Sutton's own permanent pictures, all sadly below the present standard; and we are not even content with a view of Rouen from the establishment of B. Evrard, at Lille. This gentleman achieved great success, but perfection was not to be found five years ago, even at Lille.

Now, photographers, as a rule, are economical; they certainly embark largely in fancy cameras, and paraphernalia of exceeding costliness, but we hear of them saving washing and clippings, and then troubling the assayer to transmute the residue into current coin of the realm. There is not much wear and tear in apparatus; so these two causes must be added to those named, as occasioning a bad trade latterly. You don't buy, because you don't want, new apparatus every day; and the rapidity with which a quantity of work can now be got through, reduces the necessity for seizing every suitable moment to get your portrait taken. We think an appeal to the ledgers of some of our professionals would show a great difference in favour of 1860 over 1850; if not, we are much mistaken.

Altogether we have reason, we think, to be satisfied with the present position and future prospects of the art. At the same time we are guiltless of any desire to sully the fair fame of the early operators, whose experiments every day commemorate themselves, so to speak, in every laboratory. Σ

ON THE ADAPTATION OF MACHINERY TO PHOTOGRAPHY.

By G. H. Babcock.

[Read before the Photographical Society, at the August Session.]

In this age of steam, telegraphs, and photography, when the three most subtile agencies of nature, light, heat, and electricity, have been subdued by man, and trained to do his bidding, startling developments and astounding applications in art and science are looked for as an almost daily programme in the great drama. Is it, then, to be wondered at that the go-ahead Yankee, in his impatience of the slowness of this "fast" age, should conceive and actually carry out the idea of applying steam power to the production of photographs, and should turn them out at a speed which eclipses the boasted rapidity of the "lightning" printing press?

As an evidence that this may be and even has been accomplished, I have the pleasure of presenting for the inspection of the Society, this evening, several specimens, among them a sheet containing about three hundred photographs, all printed from one negative, at the rate of *twelve thousand an hour!*

Astonishing as this speed may seem, I am assured, and from what I have seen believe, that it may be greatly increased.

The means by which this is accomplished is simply the adaptation of machinery to the process of printing by development. This process, though little used of late, has certainly produced some very fine specimens, and prints so produced are generally conceded to have the advantage in permanency over the ordinary print produced by the direct action of light.

This machine is the invention of Mr. Charles Fontayne, of Cincinnati, O., who has spent several years in perfecting it and the developing process which he uses therewith. I am assured by him that the process by which these specimens were produced is quite different from any other known, but in what this difference consists I am not informed. A negative is fixed in a box together with a sheet of prepared paper, and the latter exposed by automatic machinery to the condensed light of the sun passing through the negative. After each exposure the paper is traversed underneath the negative to present a fresh surface for the succeeding impression. These motions, together with that of clamping the negative into close contact with the paper at the instant of exposure, are all performed by the operator simply turning a crank.

The rapidity at the several times I witnessed its operation was two hundred impressions per minute, at which speed the exposure was but ·03 of a second for each impression. The condensing lens being seven inches in diameter, and the circle of condensed light about one and a-half inches, the above exposure is equal to ·65 of a second direct exposure to the light of the sun. If, therefore, the machine were to be used for a larger class of pictures, such as book illustrations and stereographs, a condensing lens might be dispensed with, and yet nearly twenty-five hundred impressions be taken in an hour!

This opens a field for photography hitherto impracticable in consequence of the time and expense of printing as ordinarily practised. The illustrations of a book, having all the requisite beauty and perfection of the photograph, may be turned out by the use of this machine with a rapidity wholly undreamed of either in plate printing or lithography. The expense of engraving may be dispensed with, and the negative come direct from the artist's hands, drawn upon a prepared glass, from which, in the course of a few hours, the plates for a large edition may be printed—each one a perfect duplicate of the original drawing. As an evidence of the facility with which this may be done, a print produced by the ordinary ammonia-nitrate process, from a rough sketch so prepared, is herewith presented. It will be seen that an ease, freedom, and spirit is given to the drawing which cannot be equalled by any process of engraving, and, when the negative is properly prepared by an experienced artist, nothing further could be desired for illustrating ideal subjects; but for the actual, and for reproducing the works of others, of course the draughtsman would give way to the far more truthful camera.

But besides book illustrations and portraits for visiting cards and advertising purposes, of which specimens are shown, this machine may be applied to the multiplication of stereographs, which, by its use, may be made so cheaply as to bring them into the humblest family, where by their exquisite beauty and truthfulness they will foster a taste for the beautiful, and in time entirely eradicate the cheap and disgustingly coarse lithographs, engravings, and water-colour daubs which at present form so large a proportion of the pictures within reach of the poor.

When these new adaptations of photography shall have been fully accomplished, then shall our noble art, which has already done more to develop and elevate the taste of the present generation than any other one instrumentality, take a stand by the side of its great sister art, Printing, and hand in hand will they go forth to educate, ennoble, and elevate mankind.

The pictures herewith presented possess additional interest to this Society from the fact that they are taken upon ordinary American writing paper, which was not prepared especially for photographic purposes. Mr. Fontayne first used this paper in his experiments on account of its cheapness, and having become accustomed to it he now prefers it to any of the foreign photographic papers. In the course of his extended experiments he has used almost every variety of American paper, including that made from straw, manilla, and cane, with varying degrees of success, and promises at some future time to present the results of these experiments to this Society.—*American Journal of Photography.*

STEREOGRAPHS.

English Lake and Other Scenery, by Thomas Ogle, *Preston.*

There has been no season in our recollection so unfavourable to the tourist as that which we have experienced during the present year; and it appears to us little less than a miracle that photographers should have been able to obtain any presentable results at all under such very adverse circumstances as have been almost universally and uninterruptedly prevalent throughout what we presume must by courtesy be called the spring, summer, and autumn of 1860. Photographers as a class are, however, of a patient and hopeful disposition: hence, when such persevering adepts as Mr. Ogle make up their minds to "carry off" a certain object, why it becomes merely a question of when—the *how* having been already settled and provided for. Accordingly we find that while tourists have been waiting for the fine weather to set in, and expecting in vain, Mr. Ogle has taken advantage of a few smiling moments, few and far between though they have been, and as the tourists could not go to "the lakes," he has brought the lakes to them; and, so well had he laid his plans, it is no lame apology that he offers to our notice, but the veritable pleasant spots in all their summer beauty. He has not only performed the task which he set out to do, but, need we say, when we have already mentioned Mr. Ogle's name, that he has done it well. Let us tell our fireside travellers what a treat is in store for them during (we had almost said the rest of) winter.

HEAD OF WINDERMERE.—There are three distinct and separate views from this spot, all with natural clouds, and each one having a separate beauty of its own. No. 139 will be that preferred by the artist, on account of the atmospheric effects and aërial perspective, which are truly charming when this somewhat sombre-looking slide is viewed in the stereoscope. Langdale Pikes, which *out* of the instrument are so blended with the clouds as to be almost indistinguishable from them, when viewed by its aid instantly attract the observer's attention, distant as they are, and robed in a gauzy garment of moisture. With No. 137—the view taken from above Bowness, with Loughrigg Fell and Langdale Pikes in the distance—the ordinary photographer will be most charmed, the picture being sharp, clear, and distinct; while No. 108 would probably obtain most suffrages from a constituency of the general public, as it possesses artistic merit in a considerable degree, and is altogether a very pleasing subject. In the immediate foreground, on a grassy knoll, a black and white cow is quietly reposing, and her figure stands out in strong relief against a mass of large trees in the middle distance, which skirt the edge of the lake, serving by the gracefully undulating outline of their tops to break the monotony of the water line. Along the right hand margin of the lake various creeks and miniature bays, with here and there a long reaching promontory clad with a verdant fringe of shrubs and little trees, may be noticed; while beyond the further shore Loughrigg Fell, dashed with a gleam of light, is backed up by the grotesque outline of Langdale Pikes, forming a pleasing contrast to the beautifully-rounded forms of the masses of soft clouds above.

No. 127. BOW FELL AND LOUGHRIGG TARN.—In this slide we have the same Pikes in the distance, but seen from a different point of view—this time bounding the vista of a long valley shut in on either side by lofty hills.

No. 109 will, without doubt, be a favourite; and deservedly so, for a happier specimen of charming English lake scenery it would be difficult to obtain. The subject is WINDERMERE LAKE, LOOKING TOWARDS LOW WOOD. The view is taken from above a huge mass of rock, and the spectator looks down upon a substantial residence with farm buildings hemmed in by a dense wood. Two or three reaches of a small river are seen to the left, embracing in its sinuosities another small plantation of trees, behind which it unites its waters with those of the lake, on the further side of which gently sloping hills, clad with abundance of verdure, interspersed with houses here and there, make up one of those views which cause the lover of natural scenery to linger long and gaze with ever-increasing pleasure.

We now come to some delightful subjects, which though of a kindred, are still of a different, class, and remind us very much of Mr. Wilson's favourite studies.

No. 103. BOBBIN MILL, NEAR STOCK GHYLL FORCE, AMBLESIDE.—This does not sound very attractive as a description of a most exquisite composition, which it is, the said bobbin mill really forming only a very insignificant incident therein—the ugly chimney-shaft being judiciously obscured by the projecting branches of a tree, under the boughs of which the water-wheel is to be seen, and from which the little fussy, foamy stream dashes and tumbles over the stony bed, half smothered by the brambles and other lowly vegetation on the bank. The mill itself is nearly hidden by some tall fir trees, which, in their formal regularity, contrast well with the somewhat straggling and dissipated-looking trees on the opposite bank.

HAWES BRIDGE ON THE KENT, NEAR KENDAL, No. 87, makes an admirable picture, though in an architectural point of view it would be held but in very small esteem. It consists of nothing more than a couple of rough stone arches—one of them only spanning the tranquil waters of the Kent—which are given with all the truth of nature. But who shall describe the mass of *natural masonry* from which these arches spring? or tell how the ivy and rushes and *equiseta* adorn the unpretending structure? On a projecting mass of the near bank is a boy fishing, and through the arch the river is seen to wind and lose itself to view behind the leafy screen of its own wooded banks.

THE WILD BROOK, BABBLING DOWN THE MOUNTAIN SIDE, No. 93, is truly a photographic gem, and would form an admirable subject for a large painting. The spectator is looking up the stream, which comes dancing down the ravine in a soft mass of foam over the huge boulders, which are smoothed and rounded by its continual play. Both edges of the ravine are clothed with shrubs in wild luxuriance, and the whole is seen through a vista formed by the overarching boughs of a birch tree and a holly on opposite sides of the stream.

As a contrast to the preceding we must notice No. 76, which presents to us a phase of nature in calm repose—a stream of water, smooth as the surface of a mirror, reflecting the low bushes on the wall, and the tall elms behind. It is thus described:—

> "Here could I stand and muse and muse,
> And dream fresh fancies as the stream glides on."

From Westmoreland we get some very beautiful illustrations. Two taken from NEAR RYDAL MOUNT, Nos. 91 and 92, are very similar in character, and both perfect in manipulation. The subjects are very difficult to render truthfully by photography, in consequence of the dense mass of foliage contrasted against the light-reflecting surface of the stream; yet we can with truth affirm that the execution of these two specimens leaves nothing to be desired: the foliage is not too dark, nor is the water too white. The more they are examined the more they are appreciated. We have already stated that both are beautiful, but in No. 91 especially there is a whole volume of poetic fancy embodied. As an art-composition this would command universal attention and admiration. The subject is a wild ravine, along which a mountain stream rushes over the rocks which, at irregular intervals, stand out in bold relief, draped with soft mosses kept in constant luxuriance by the ever-moistening spray. In the immediate foreground are some unusually large masses, and these are hemmed in by very tall trees which join overhead throwing three-fourths of the whole subject into deep shade; but, deep as the shade is, every detail of branch and leaf is just as visible as in nature. A small portion of sky only is to be seen, and that through the upper branches of the trees. The stream, soft and pearly in tint, occupies but a small portion of the entire area; but in the more distant part of the ravine, where the upper foliage is less dense, a glorious burst of light comes in which gives vigour and fresh value to the whole. This is one of the finest specimens of its class that we have ever had the pleasure of examining.

THE UPPER FALL, No. 96, and THE LOWER FALL, RYDAL PARK, No. 95, are also exquisite in subject. The former, though very good, is a little over-developed, and consequently spotty. Mr. Ogle's general high standard may have made us somewhat hypercritical. But the "Lower Fall" is peculiarly charming, the water streaming in soft foam down a steep declivity, and the magnificent fronds of graceful ferns projecting from the perpendicular rocks on the left.

In addition to the Lake Series, we have also before us several admirable vews of RAGLAN CASTLE, KENILWORTH CASTLE, and TINTERN ABBEY, all executed with the same skill that we have been so pleased to recognise in those already noticed. Amongst those of Raglan Castle we prefer No. 3, THE VESTIBULE LEADING TO THE BANQUETTING HALL; but where all are so good it is difficult to select. Of the Tintern Abbey collection, two, which we may designate as semi-interiors, are especially pleasing, being Nos. 23 and 24, representing the principal aisle—one from the east the other from the west, the former containing the picturesque west window. With regard to the printing and toning of these stereographs, we can only say that they are unusually fine, being of a rich, warm, brownish-black tone, and without flaw of any kind.

We could well have given a more detailed account of these last-mentioned productions, but space will not permit us to do so on the present occasion. We are highly gratified to find that, in spite of the unfavourable season, the practice of stereoscopic photography at least has progressed at a far more rapid pace towards perfection than we could possibly have anticipated. We are indeed surprised as well as delighted with what has been achieved. We have already described some of the beauties that are to be had: we have others of a different character yet to lay before our readers, which we hope to be able to do in our next.

Letters to a Photographic Friend.

No. VI.

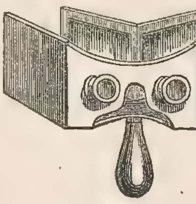
DEAR FRANK,

I proceed to tell you of the things that interested me at the other houses I visited in the city.

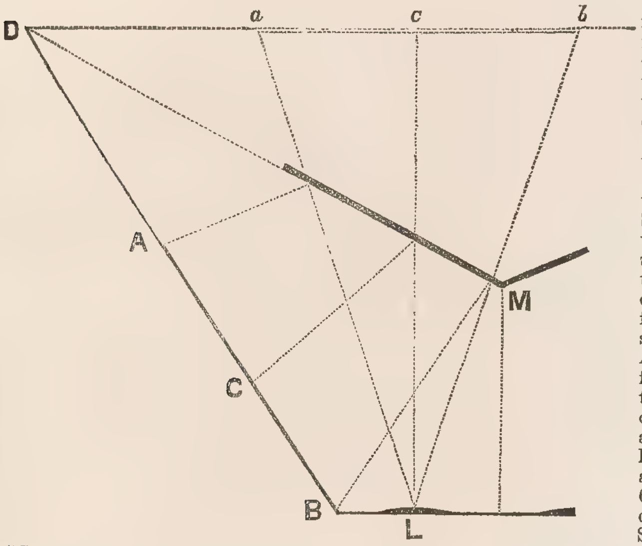
At Negretti and Zambra's I had brought under my notice a series of transparent stereoscopic views of the scenery and natives of Japan, executed by the photographer sent out there by this firm. These were of great interest, and the groups of Palms that predominate in nearly every view are exquisitely rendered. How long will it be before we have the characteristic Flora of the various phytogeographic regions of the world brought home to our firesides by means of camera and stereoscope? May this instalment be quickly

followed by similar ones! One slide gives a capital idea of the external and internal aspect of the fruits of the country, others of the physiognomy of the male and female natives of Japan, or of their habitations and surroundings.

I next turned my steps towards Mr. Cox's, of Skinner Street, Snowhill. Here I had an opportunity of examining Mr. Sutton's new form of stereoscope. The form of this instrument I will convey to you by means of the annexed sketch. The framework placed at an angle on each side of the lenses is for the support of the two pictures, and the angular portion opposite the lenses consists of two plane mirrors, that reflect each picture into the axis of each lens. The lenses are plano-convex, of six inches focus, placed two inches and a half from centre to centre: they are entire, and may be achromatic if desired. The pictures are four inches square, the negatives of which are taken in a twin-lens camera, on a plate eight and a half by four and a half inches, placed in "a non-reversible slide"—that is to say, with the film on the back instead of the front of the plate, so that the two views are taken right *through* the glass. The lenses of the camera *must be* of the same focal length as those in the stereoscope, viz., six inches, and placed four and a quarter inches from centre to centre. This arrangement is *necessary* that the objects may not appear *reversed* when inspected in the stereoscope, and that they may produce an idea of magnitude.



Mr. Sutton thus describes the geometry of this instrument by aid of the annexed diagram:—



"Suppose the pictures to be four inches square, then the distance Lc must be six inches. Set off ca, cb, equal to two inches, and join the line b B (not shown in the figure), B being the nearest corner of the left picture. Bisect b B at right angles by the line D M. This gives the position of the left mirror, and by joining D B you get the position of the left picture A C B.

"It will be seen that $a\ c\ b$ is the virtual image of the picture A C B, C being the point where the axis of the camera cuts it. This reversed image is formed by reflexion in the manner shown by the dotted lines.

"According to this construction the axes of the eyes are parallel when directed towards the centres of the pictures, that is, towards the points in which the parallel axes of the lenses cut the pictures when a twin-lens camera is employed. But it must not be supposed that the same object C in both pictures is always united at an infinite distance; for when the axes of the lenses are parallel the same object does *not* occur in the centre of both pictures unless that object is at an infinite or very great distance. The images of near objects will be united by converging the optic axes at the same angles as in natural vision."

I examined several stereographs in this reflecting instrument, and they certainly conveyed an idea of the magnitude of the objects delineated that is not attained by the lenticular stereoscopes we have been accustomed to. I could not detect any signs of distortion in the stereographs brought under inspection; and the instrument occupies no more space than an ordinary stereoscope, so that it may be regarded as an improvement on the old forms, and a step in the right direction.

Mr. Sutton, I found, had just sent Mr. Cox a box of negatives taken by his Triplet and Panoramic lenses, that those interested in these inventions might have an opportunity of criticising their respective merits. The subjects of these negatives are certainly most *judiciously* selected for the purpose of criticism, for there is hardly a line perfectly straight to be found in these views whereby to test the lenses as to their freedom from *distortion*; and there is such abundance of foliage at the marginal portions that it is difficult to know whether parts wanting in definition are to be attributed to defects in the lenses or to motion of the foliage caused by wind.

With regard to the negative produced by THE TRIPLET, this is taken on a plate 10 by 10 inches. The focus of the lens employed was fourteen inches and a half. Therefore the surface covered is, in relation to the focal length, in the proportion usually considered as fairly available, viz., two-thirds; for if, in round numbers, we call the focal length 15 inches, $\frac{2}{3} = 10$ inches. The size of the stop employed is not stated. As there appeared to be a distortion of the "pincushion" kind in the rendering of a chimney in a cottage, and this in the marginal corner of the negative, I compared the negative with one of the four-inch stereographic prints of the same subject stated to be taken from the same spot, and, on measuring with a goniometer the angle between the slope of the roof and the perpendicular line of the chimney, I found, as the eye indicated, that there was a greater angle formed in the view rendered by the triplet than in the one taken by a stereoscopic lens of six inches focus; moreover, *in the negative, the angle increased* at the *upper part* of the chimney, whilst in the stereoscopic print the perpendicular line of the chimney was straight from the top to the base. This seems to confirm the suspicion (of course only founded on the evidence of the single negative sent to London for the purpose of being criticised) that the triplet, as at present constructed *or manipulated*, gives the "pincushion" distortion at the marginal portions of a field that it might fairly be expected to cover without a fault. Mr. Sutton contrasts this 10 by 10-inch negative with a negative of *the same size* taken by a Ross's landscape lens of *nine inches focus, with a quarter-inch stop;* and on a label attached to it he calls attention to the "frightful distortion of the chimney on the left." There is no question about the frightful distortion. They say "comparisons are odious," and the saying holds good in this instance, because they are not fair. Apply the same rule to Mr. Ross's lens, as to the proportion of field that it might fairly be expected to cover without distortion, then $\frac{2}{3}$ of 9 inches$=$6 inches. Therefore Mr. Sutton ought not to expect it to cover a plate of 10 inches square, and put it in comparison with his lens of $14\frac{1}{2}$ inches focus. But on his label he asks people to observe that "not more than a diameter of six inches is passably good;" but this surface of 6 by 6 Ross's lens is free from distortion, which is more than can be said of the surface of 10 by 10 covered by Mr. Sutton's triplet. Mr. Ross, in his catalogue, only professes to render pictures 6 by 5 inches with his No. 1 lens of 9 inches focal length. *Beyond* these limits distortion begins to make itself apparent. The negative from THE TRIPLET ought to have been put side by side with one from a Ross's No. 3 lens, of 15 inches focal length, which is put forth as covering a surface of 10 inches by 8, for the comparison to be anything like a fair one. Moreover, it would have been better if both negatives had rendered the same view from the same spot, which is not the case.

I also examined a negative on curved glass, taken by the panoramic camera, which included the two views rendered on the two 10-inch by 10 negatives I have just referred to. This specimen of what the panoramic lens is capable of is decidedly superior to the negative exhibited before the meeting of the London Photographic Society, which is still in Mr. Cox's shop; but whilst the middle and left-hand sides are in parts well defined, the right-hand portion is very weak. Whether to attribute this to an unsymmetrical fault in the lens, or to the curve of the glass plate, or careless manipulation of the film, I know not; but I do not think this perceptible inequality in the character of the negative is attributable to inequality of illumination of the subject. The objects delineated in the negative are nearly all in the same plane, there-

fore it does not afford an opportunity of judging of the "depth of focus" said to be a characteristic of this lens. The angle of view is extraordinary; and if this form of lens and camera were brought to perfection, I think it would be *the* instrument for military and naval purposes. If for the latter service, the camera should be mounted on Professor Piazzi Smyth's "free revolving stand" or gyrating apparatus, described in his work on Teneriffe, so as to render the instrument independent of a ship's motion.

Finding that I could not "do" the entire City to-day, I retraced my weary steps to the "Garden." In my next I hope to describe what I saw in my visits to the remainder of the City establishments.

And so remain,
Yours for ever,
SIMEON HEADSMAN.

Meetings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The first ordinary monthly meeting for the season of this association was held at Myddelton Hall, Islington, on Wednesday, the 26th ultimo,—George Shadbolt, Esq., V.P., in the chair.

Mr. John Barnett, the honorary secretary, having read the minutes of the last meeting, which were confirmed, the ballot for new members took place, when Mr. J. T. Bell was unanimously elected a member of the society.

The chairman then introduced to the meeting some fine stereographs, the production of Mr. Ogle, of Preston, representing Tintern Abbey, Raglan Castle, and English lake scenery. [For a notice of these, see page 285.]

A Member observed that the specimens appeared to be a little over-printed, to which

The Chairman replied that the objection made would not be observable in the stereoscope.

G. Wharton Simpson, Esq., exhibited some specimens of waxed albumenised paper negatives, possessing great sharpness, produced by a new process not yet published. The inventor is Mr. H. Hooper, of Manchester.

Mr. Hill expressed his opinion that they would be more suitable for large than small pictures.

The Chairman replied that, in his opinion, they would be suitable for either stereoscopic or large negatives.

Mr. Bingham stated that, in preparing some dry plates, he had experienced some annoyance from the production of blisters on the film. He found he had been able to correct this by applying a coating of dilute albumen.

The Chairman remarked that that was the course usually adopted by albumen operators.

The Chairman having vacated the chair for the purpose of reading the paper of the evening, —— Moens, Esq., temporarily took the chair, when

Mr. Shadbolt read a paper on *The Photographer's Tripod*. [See page 281.]

Messrs. Dawson and Hughes having commented on the mechanism of the stand exhibited, were of opinion that, with the view to avoid a tendency to vibration, it would be necessary to construct the lower limbs of the tripod below the hinge. Mr. Hughes added that, for his own part, he preferred the mode of construction adopted by Mr. Shave.

The Chairman observed that as greater strength was imparted to the hinge joint—the plan proposed by Mr. Shadbolt—his tripod might fairly be considered an improvement on the old form.

Mr. Hughes asked Mr. Shadbolt's opinion whether ash would not be the best material for the legs of the tripod?

Mr. Shadbolt, in reply, said that in the tripod now before the Society the legs were of plain Honduras mahogany, a wood which he had always recommended for photographic purposes; but the wood which he would strongly advise for the construction of tripod stands was Norwegian or Baltic yellow deal.

The Chairman inquired how light metal bars would answer in place of wood for tripod stands?

Mr. Shadbolt replied that metal would cause a great deal more vibration.

A vote of thanks was then unanimously passed to Mr. Shadbolt for his paper, when he again resumed the chair.

Mr. G. W. Simpson exhibited some specimens of arrowroot-paper, presented to him by Herr Paul E. Liesegang, the editor of *Photographisches Archiv*, on his recent visit to London.

In the course of conversation which followed,

Mr. Hughes was led to make some observations on artificial ivory, which, he stated, had been known in the French market long before Mr. Mayall had patented it in this country. In operating with this material, by which he had obtained one of the best photographs he had ever seen, he had found, on developing and washing, that it curled like common glue. He did not clearly see his way commercially in following up this process.

Mr. Cramb, of Glasgow, observed that, although a picture on ivory could not be produced in the ordinary manner without the grain showing, not only in the white but the black portions, yet, by a slight modification, he had never experienced any difficulty in producing photographs on ivory.

Mr. Wall expressed his opinion that ivory lost its transparency, and was not to be compared with paper.

Mr. Dawson remarked that the greater part of the ivory introduced into this country was "fossil ivory," which must have been buried for thousands of years, and this might account for the differences observed in the colour and structure of recent ivory.

Mr. Mainwaring then exhibited some beautiful coloured photographs, illustrative of our most favourite flowers, representing gloxineas, dahlias, and bigonias.

The thanks of the meeting having been given to the Chairman, the Society adjourned till October 31st.

FROM THE SOCIETY OUT-OF-DOORS.

Oh! if you please, I am the society which has been turned out-of-doors. Turned out-of-doors! and in this weather too! when only twelve months old, by my own parents, without whom I had not been in existence! No other society has been so treated. What have I done to deserve this? The excuse has been utility. I have been told that I must become strong and healthy, and able not only to help myself but others; that if I don't work, and work well, there is no reason on earth why I shouldn't die, and be decently buried. Very well; if this be true, why don't you serve us all alike? why should I be selected, the youngest, and consequently the weakest? All I say is, if it's good for one it's good for all; turn them all out, then, for three months a-year. That's what I say.

There — that's off my mind! and now I'll send you a report of

THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

LAST OUT-DOOR MEETING.

The Committee, which had only met on the previous Wednesday, selected for this meeting of Saturday, September 15th, Epping Forest. The rendezvous being appointed at "The Eagle," Snaresbrook, at 2.15 P.M.*

The locality is one well adapted for the purpose, the scenery being of a truly picturesque character, and the distance from London very short.

Some gentlemen had started at a very much earlier hour than that appointed, and the President was not able to reach "the scene of operations" until half-past three o'clock, but most of the members were present at the rendezvous. The number of cameras there were sadly too few, and various reasons were given for the fact: some alleging the uncertainty of the weather, others the difficulty of conveying the apparatus for their process—the wet; but Mr. H. raised a laugh by giving for *his* reason that he had to start from that spot for Brighton; and when asked if he were going there for pleasure, innocently replied, "Oh, no!—it is to fetch my wife."

The first views (very pretty sylvan bits) were taken in the road by the railway station, the others from spots farther in the forest, taking a road past the sheet of water in front of "The Eagle."

Messrs. Tear, Borchert, and Ackland were testing Messrs. Petschler and Mann's new process. Mr. Tear has since informed the Secretary that the five plates he had prepared turned out quite satisfactory as far as this process was concerned, developing evenly and without stains. They were soaked for about fifteen minutes in water after albumenising, and thoroughly washed under the full force of the tap. M. Borchert thinks success by this plan is greatly dependent upon the collodion's character, and found his best pictures by it were produced with the more porous collodion. Mr. Ackland's Petschler and Mann plates were the victims of a rather singular accident. During his absence from home the gardener had swept into some apertures left for ventilation at the bottom of his laboratory (which chances to be in the garden), leaves, gravel, &c. The decomposition of the vegetable matter generated foul air, which acted upon the plates while they were being prepared, just as the fumes of ammonia might have done, and so produced fogging.

Several plates prepared by the linseed process have since turned out "excellently well," especially some which were said to have received a perfect washing subsequent to the application of the linseed.

As the members of the Society passed along, laughing, chatting, and joking, a little army of photographers bearing tripod stands and cameras, no small wonder distended the eyes of passing rustics.

In all, nearly forty plates were exposed; but, had the day proved less unpromising, more than double that number would have received images. Several showers fell, and darkness came on so rapidly that all regretted both that this was their last out-door meeting and that an earlier hour had not been named for the rendezvous.

After rambling about the forest, focussing and exposing, discussing matters photographic, and displaying the best of good fellowship, the party adjourned to "The Eagle," and partook of a capital tea, discussing some excellent ham and eggs, with a relish which was in itself a very good proof of the wisdom of adopting such out-door meetings. After tea the meeting was resumed.

* The announcement of this meeting, it will be easily seen, could not have appeared in this Journal, as it would otherwise have done.

One of Mr. Skaife's "chromo-crystals" having been handed round, some discussion ensued in reference to the real value and importance of the "pistolgraph," the difficulty of focussing being chiefly dwelt upon. Some suggestions were also made with reference to Mr. Skaife's method of obtaining an instantaneous exposure, and in discussing an optical question involved. Some statements made by Sir David Brewster were combated. A very artistic little picture, taken with a telescope glass, was shown by Mr. Davis, together with some specimens of failures.

The Rev. Mr. Statham, the President, said he had been thinking over a matter which he desired to lay before the meeting. In the first, or one of the earlier numbers of the new German journal, some hints were found as to the advisability of publishing a general index of reference, by which photographic students might see at a glance what had been said or done in reference to any one subject, process, or other matter in connexion with the art. The special utility of such a work would be at once apparent to photographers, inasmuch as articles of value on the various branches and theories were so scattered, and the journals and magazines in which they were to be found were so numerous, and of so varied a character, that many valuable matters must necessarily lose much of their utility, and finally become lost altogether. Such a *Catalogue Raisonnè*, as it might be termed, would be of infinite service to our own Society, and to others. Photographic literature was now in its infancy, but it was rapidly growing, and that which was now practicable might in ten years time be out of the question. He (the President) thought the Society might take some steps in this direction; most or all of the societies had originated such works, and with reference to that of the Royal Geological Society he, as a member, could speak very highly indeed of its great importance and utility. Undigested knowledge in scattered morsels could not compare in power with knowledge properly systematised, arranged, and concentrated.

Mr. Wall warmly advocated the adoption of such a system, but feared it was a task of greater difficulty than it might appear. To compile such a work would demand no little time, labour, and expense. Now, the South London Society was very young, its exchequer very low, and the tasks already undertaken were at present, considering the means in hand, quite enough to occupy its time and attention; but, as Secretary, he would willingly try to aid in carrying out such a suggestion in any way he could. Perhaps, if he found it necessary, he might ask the members to elect another secretary, with whose co-operation and assistance it might be accomplished, not in reference to the past, but the future. He (Mr. Wall) would also suggest that a combination of subscribers from amongst the members of kindred associations might take up such a design by appointing a committee of their number for its management, and ensuring some respectable publisher against loss by its publication. He believed such a book would command a large and ready sale.

Mr. Hughes said he was glad this subject had been brought forward, although he feared there were many difficulties in the way of realising their Rev. President's suggestion. Such a work ought to have been one of the earliest tasks undertaken by the parent society. Its utility would unquestionably be very great, and its importance to the art-science itself equally so. Many valuable papers on photography had appeared in such pages as those of the *Athenæum*, *The Times*, the *Quarterly*, the *Chemist*, *Notes and Queries*, and many others, the existence of which might only be preserved to photographers and experimentalists by a good *Catalogue Raisonnè*. In the present rapidly advancing state of photographic literature it was more than probable that this task, now perhaps practicable, would soon become impossible. From every point of view the matter was important; and, perceiving that Mr. Wharton Simpson was present, he would hint that the matter was one well worthy his editorial consideration. A regularly organised system of chronicling the character and the whereabouts of all papers of sufficient importance would be very advantageous. He was happy to find the Society's officers took such an active interest in its affairs. There was, unfortunately, too strong a tendency in young societies generally to fill their executive departments with officers elected rather with a view to their eminence in rank, or high position in public estimation, than to ability and fitness for performing the duties of their office.

Mr. G. Wharton Simpson had a very high opinion of the President's suggestion, but feared it was far too comprehensive a subject to fall within the province or power of a journalist. With regard to the particular journal under his charge, however, a more complete, copious, and systematised index of the past volumes, such as would in fact form a *Catalogue Raisonnè*, would probably be issued upon the completion of the current volume.

The President wished to draw attention to a suggestion previously put forward in the Secretary's annual report. It was very desirable that a collection of works by standard photographic authorities should be established as a library of reference in connexion with this society. Copies of all important works were presented to our chartered societies, and, doubtless, such would soon be received from the liberality of photographic authors or publishers if an appeal were made in the Society's behalf.

Mr. Hughes thought libraries were seldom of much service when unconnected with local homes; but he should be glad if a collection of such works as Hardwich's Chemistry, Sutton's Dictionary, Robert Hunt's Works, and others of equal importance, could be procured. Desirous as the thing was, there were some difficulties in the way of its establishment. The books, however, might be issued to members, and returned to the librarian once a month, in which case they must be kept at the place of meeting.

Mr. Wall said he would undertake the duties of librarian until these duties grew too heavy for his leisure—of which, however, he had not too muchj ust now; and a box should be provided for the books when the books were provided for the box.

Mr. Davis said he would, by way of example and beginning, present the society with a copy of Hunt's *Researches on Light*.

Mr. G. Wharton Simpson would also present copies of two little works—*The Photographic Teacher*, and *Harmonious Colouring applied to Photography*. He would also place the name of the Society on the list for presentation copies of the *Photographic News*.

Mr. Hughes, speaking of a suggestion of the President's, in reference to getting up an album of photographic celebrities, said it was an old saying that the shoemaker's wife was always ill shod; and its meaning held good with photographers, for while albums of all sorts of celebrities had been got up, we had yet to originate one devoted to photographic celebrities. Poor Archer had gone, and Daguerre, but many of the art's best friends still remained, labouring in the cause for which they had done so much. There were Fox Talbot—with whose face how few photographers were familiar!—Sir John Herschel, Sir David Brewster, Professor Wheatstone, Claudet, Robert Hunt, Rev. J. B. Reade, Dr. Diamond, and many others. He would initiate the movement by giving a portrait of Mr. Reade, from whom he had recently had a sitting.

Mr. J. A. Cotton, on behalf of his firm, would be glad to photograph any of such celebrities who would favour him with a sitting for this purpose. He had done very little for the society in any shape at present, but hoped to do more in future.

Mr. Wharton Simpson would present a print from his negative of Mr. Sutton.

Mr. Wall would provide a portrait of Mr. G. Shadbolt.

Mr. J. A. Cotton said he thought another album might be got up as a register of the more unaccountable kind of photographic failures. The best way of recognising the particular character of failures in your own productions was to see them in those of others. Some failures were very puzzling to account for, and a collection of such, for reference, might tend to throw light upon their origin, or even some perfectly new facts in relation to the science or art.

Mr. G. Wharton Simpson thought Mr. Cotton's suggestion a very happy one; but it would be important that such failures should be most carefully described, and have all their attendant circumstances fully detailed, otherwise the collection would only tend to increase confusion.

Mr. Wall said in no case ought failures to be adopted for the proposed album until they had been laid before the Society at one of the monthly meetings, to be duly inspected, discussed, and ratified by the members present.

Mr. Hughes also hoped that the utmost strictness and care would be exercised in the choice of such failures, and in impartially criticising the description given of their origin, inasmuch as the Society would lend its authority to the work, and become responsible for its character.

Other remarks were tendered on the subject by those present, and several members pointed out in how many cases valuable results had arisen from supposed failures. Messrs. Petschler and Mann's discovery, he believed, arose from what might almost be termed a failure; and a long list of similar cases were instanced by Messrs. Hervè, Hughes, Simpson, and others.

In the course of the evening another suggestion was thrown out relative to the advantage of procuring stereoscopic photographs of all the more valuable novelties in the way of apparatus.

Three new members were elected, Mr. Roberts, Mr. Holles, and Mr. Deberskey.

Thanks were very heartily awarded to the chairman, on the motion of Mr. Hughes.

Mr. G. Wharton Simpson said they had been guilty of a sad omission at their annual meeting. Not only did this Society owe its origin to their Secretary, but its present healthy position was mainly due to that gentleman's untiring energy and disinterested exertions in its behalf. After working hard twelve months for them, expending some money, more time, and still more thought and effort, he had not received even a vote of thanks. He therefore begged to move, as the nearest approach to an *amende honorable* they could make, that such thanks be now awarded.

Mr. Herve having cordially seconded the motion,

A vote of thanks was then received by Mr. Wall, and the meeting shortly afterwards resumed its sitting in the railway carriage, passing, as the President said, over the sleepers as a wide-awake young society should, and progressing rapidly as we hope it may continue doing.

The following papers were announced for the next meeting, which will be held in the school-room beside St. Peter's Church Gates, on the 18th of October:—

On the Best Mode of adapting Portrait Lenses to Landscape Photography. By Mr. C. Jabez Hughes.

On the Photogenic Action of Colour. By Mr. T. Clarke.

The Secretary stated that steps having been taken for forming the proposed "Experimental Committee," one or two "Jottings" relative to

experiments of more or less value might be expected from the same at each of their future meetings, excepting, perhaps, the first of the session, although he trusted such committee might at once get into working order.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

The first meeting of this Association, after the summer recess, was held at the Chorlton Town Hall, on the 12th ult.,—Mr. Griffiths in the chair.

The Secretary read the minutes of the last meeting; which were confirmed.

The Chairman then addressed the meeting as follows:—

Gentlemen,—On this our first meeting after the vacation, I should like, with your permission, before proceeding with the ordinary business of the evening, to make a few observations *On the Present Position of Photography, Viewed as an Art and Science Educator;* and also *On the Present Unsatisfactory State of our Knowledge with Reference to the Chemical Nature of the Various Changes Involved in the Production of the Photographic Image, together with a Short Account of the Working of some of the Negative Processes.*

The subject is so vast a one as to make it impossible for me, in the short time I dare venture to trespass on your patience, to do anything like that justice to it that I should wish; therefore I shall content myself with merely calling your attention to those points that appear to me to be of the greatest importance.

We have been highly favoured in our day, for we have lived to see the gradual development of three of the grandest discoveries that it was ever permitted man to make—the railway system, the electric telegraph, and photography.

By the operation of the two former, time and space may be said to have become almost annihilated; and by means of the latter we are enabled to hand down to posterity not merely dry verbal descriptions of persons, places, and scenes, as formerly, but faithful, speaking images, drawn by the unerring hand of Nature herself. No one, I think, will deny the immense benefit that has accrued to the human race from these discoveries; not only as aids to civilisation, by breaking down the barriers interposed to the free intercourse and interchange of thought and opinion between nations, but by supplying a fresh stimulus to scientific and chemical investigation.

The part played by photography in this great work may not appear at first sight so apparent to the casual observer, simply because its sphere of action is the human mind; and it is, consequently, only in the lapse of time—like all other influences, whether for good or evil, to which it is subject—that we must expect to see any decided and palpable effects of its operation.

Even now, although ten years have scarcely elapsed since the lamented Scott Archer freely made his discovery of the collodion process known to the world, its effects on the great mass of the people are becoming more and more apparent in the improved taste and love for art which is exhibited, not only by the middle and higher classes, but even by what are termed the uneducated classes of society. As a proof of this, I need only instance the vast and increasing number of amateurs from the lower walks of life who now practice the art, and who have, from being careless or indifferent observers of what is beautiful in nature and art, become enthusiastic admirers of all that tends to ennoble and elevate the human race.

It is in this way, I conceive, that photography may be safely considered as one of the great aids to the civilisation and improvement of mankind.

I may not, in confirmation, inappropriately refer to some of the commercial aspects of photography; to the thousands of our fellow-men who now find useful and profitable employment in its practice; and to the great stimulus it has given to optical and chemical discovery.

I should have a difficult task to perform were I even to attempt to name all the various uses to which it has, up to this time, been applied. I shall, therefore, merely allude to those which more particularly claim our attention.

Portraiture, being the first great practical use to which it was put, demands more than a passing observation. If we would know the estimation in which it is held, we have only to take a walk through some of the streets of our towns, noting down the number of galleries we everywhere see. There can be no greater proof than this that the services rendered by photography are highly appreciated by the great body of the people. Ask the husband who has lost a dear wife, the wife who has lost a husband, the father who has lost a child, what value they place upon the frail and delicate image which photography alone has enabled them to possess, and you will no longer have any doubt of the important position our art is entitled to.

Landscape photography, the next in order of usefulness, I shall pass over by observing that we are far yet from having obtained that perfection in it which portraiture has attained: partly from the nature and construction of our lenses, embracing, as they do, so much smaller an angle of view than the eye; and also because of the lengthened exposure we are obliged to give, consequent on the smallness of the aperture required for the sake of having all in good focus, during which time the aspect of the scene is constantly undergoing a change in the variations of its lights and shadows, the movement of trees, foliage, and living objects. A wide field for research is open to the enterprising experimentalist in this department, who should not rest satisfied until the improvement in his lenses is such as that the angle of view embraced by them shall more nearly approach that of the eye, and until he has made such improvements in the dry processes as to make them equal, at least, in rapidity and certainty to the wet collodion process. Both these objects, I am persuaded, can and will be ultimately attained.

The next great use to which it has been applied is that more immediately connected with trade and commerce—the copying of machinery, plans, maps, paintings, and numerous other objects. This department has attained an importance and a perfection almost equalling that of portraiture.

The last uses, though not the least important, to which it has been applied, and that I would call your attention to, are those connected with microscopical and astronomical science.

Its application to both these sciences promises well to be of the greatest benefit in their popularisation and advancement.

Having now, though very imperfectly, placed before you some of the facts and the reasons why photography must be considered a great art and science educator, I would specially call your attention to the second part of my subject—the Chemistry of Photography.

If this department had only received a tithe of the attention that the mechanical has, I should not have to regret that our knowledge is so meagre and our opinions respecting it so conflicting. Some few individuals, it is true, both in this country and in France, have specially devoted their energies to it, and our thanks are particularly due to them for the little knowledge we possess. But this is not sufficient. Besides, we have no right to expect that they will continue their investigations, involving, as it must to them, a great loss of time and money, and all for our benefit.

There is scarcely one amateur or professional who has not taxed his inventive powers to improve the manipulative and mechanical department of the art; and the consequence is, the comparatively high state of perfection they have now attained.

But the chemical department, though far outweighing the other in the importance of the results that may be expected to arise from a more general and energetic study of it, seems to be viewed by the majority of photographers with something like the aversion that the schoolboy looks upon the solution of some difficult geometrical problem. To show you the necessity for this department receiving a greater amount of attention and study, I have only to remind you of some of the as yet unexplained facts and phenomena connected with the collodion process alone. Take collodion itself. What amount of knowledge do we possess respecting the changes, chemically, which we all know it undergoes by long keeping? Why do we experience such great difficulty in obtaining it of uniform and unvarying quality, even from the same maker? Is it not mainly owing to the defective state of our knowledge as respects the preparation of pyroxyline? Cotton is a definite compound of carbon, hydrogen, and oxygen. Gun-cotton differs from it only in the substitution, atom for atom, of part of its hydrogen by peroxide of nitrogen; and it is according to the extent that this substitution has proceeded that we obtain so many varieties of it, each differing so greatly in its properties and suitability for photographic purposes.

A careful analysis of that variety which is found from experiment to answer all or most of our requirements, particularly with reference to the per-centage amount of peroxide of nitrogen it contains, would, it seems to me, be a great step in advance. Our next object then would be to ascertain by careful experiment the exact strengths of the mixed acids, and the temperature, as well as the time of immersion, necessary to produce that variety. To produce a definite chemical compound certain fixed and invariable conditions are necessary, and these once known and acted upon, we cannot fail in arriving at a successful result.

Some years ago Professor Hadow gave to the world the results of his experience in the shape of a formula for the production of a definite gun-cotton, suited to the manufacture of collodion; but, however strictly it may be followed, the result is not always perfectly satisfactory. More recently Professor Hardwich has taken up the subject experimentally, and has given us a formula which differs widely from that of Professor Hadow, but I cannot say that it produces better or even as good results. It is quite clear, then, that there is room for further experiment in this direction. We all know from experience that a collodion plate made sensitive in an alkaline bath produces a picture enveloped in fog; and that one excited in a neutral bath is more readily acted upon by light than it would be if excited in one that is acid. A satisfactory explanation of these facts has yet to be given. Our information is equally defective as to the part played by free acids in our developing solutions. Various theories have from time to time been put forth in which an attempt has been made to explain the precise nature of the action of light upon salts of silver; but further corroborative proofs are wanting before we can decide with certainty which of them, or if any, is the correct one. The future advancement of photography to the position of an exact science depends mainly upon this point being satisfactorily cleared up. That done, we should not be startled out of our propriety, as we occasionally are, by the announcement of some such extraordinary (because unexplained) facts or phenomena as the *reversed* action of light on an over-exposed plate; the gradual fading out of the invisible image on the dry plate when kept too long before development, as also its obliteration when exposed to the vapours of iodine, acetic or nitric acid;

the development in daylight of a collodio-albumen plate, after the removal of the iodide of silver; the non-sensitiveness of dry collodion, when a slight trace of any soluble chloride, iodide, or bromide is present, and the return of sensitiveness by simply washing it away.

I could point out to you, if it were necessary, a great number of other facts that require explanation; but I trust I have done sufficient to excite in you a determination to commence a course of careful experiments, with a view to clearing up some of the mysteries that beset our art.

I will now, lastly, say a few words on some of the numerous processes followed in the practice of landscape photography.

I have personally had a limited experience of the wet collodion, the oxymel, the gelatine, the gum, the collodio-albumen, the milk, and the simple dry collodion processes, and have succeeded in obtaining fair, though varying results from all. If I were asked to which I should award the palm, I should hesitate, as I believe them to be all equally good in the hands of a practised manipulator. Were it not for the great drawbacks to its successful working in the open air, I should feel inclined to give the preference to wet collodion—not so much from the beauty of its results, but simply from its rapidity and the satisfaction one feels at coming away from some favourite scene with negatives one can look at. It is more followed than perhaps some of you may be aware, particularly by professional photographers. The new process of Messrs. Petschler and Mann, called by them (although inaptly, as it is more nearly akin to the Fothergill) *a modification of the collodio-albumen process*, promises to become highly popular from the simplicity of the manipulation required. But far outstripping, to my mind, this, and all other dry collodion processes, is the *improved patent process of Dr. Hill Norris, of Birmingham.* I confess that, until lately, I have been somewhat sceptical about it; but, from results recently seen, I have no hesitation in saying that it is, as described, "fully equal in sensitiveness to wet collodion, without any of its attendant disadvantages."

Before I conclude, I feel it to be my duty to refer to the untiring energy our treasurer, Mr. Hooper, has always displayed in his efforts to improve the negative paper processes. We all know that paper negatives, apart from the long exposure they require, rarely equal in definition and sharpness, particularly in foliage and in distances, those on glass. This no doubt arises from two causes:—the want of uniformity that all paper presents, and the formation of the image in the body of it and not on the surface.

He has succeeded in producing a paper almost, if not quite, equalling in sensitiveness and sharpness the collodio-albumen process.

As he is himself present, I will leave him, as better qualified, to make any further remarks upon it.

I will not continue further to tax your already overstrained attention, but conclude by thanking you for the patience yon have shown in listening to my imperfect remarks.

Mr. Hooper then handed round to the members several specimens of negatives and transparent positives. He said they were prepared by coating the paper with plain albumen, coagulating it by immersion, or floating it on alcohol after drying, which was rapidly accomplished. He coated with iodised albumen, prepared by mixing as a formula—

Iodide of Potassium	25 grains,
Bromide of Potassium	3 grains,
Albumen	1 ounce,

well frothed, again coagulated and dried, sensitised on the nitrate of silver bath, washed in plenty of water, and hung up to dry. The formula was not perfect yet, although the specimens were on the whole better than he had expected; but he wished to make the Society acquainted with the results of his experiments. He had found it very successful in copying in the printing frame, but it was hardly as good in the camera as he wished; however, in his opinion it was sharper than waxed-paper. For printing positives it answered very well; and, from being so sensitive, they could be printed by gas-light in the evening, which he was sure would be an advantage to amateurs, enabling them to produce prints on paper after dark.

Mr. Wardley remarked that, if this process could be made to work for positives, it would be very useful to enable persons to print in dull weather or in the evenings, and by all means urged upon Mr. Hooper to go on and perfect it; but for his part, he hardly expected to find it better than *good* waxed-paper for negatives.

Mr. Adin should be disinclined to abandon the waxed-paper process for this: he did not care for such extreme sharpness. He had a positive which had been moved in the printing-frame probably to the extent of one-fiftieth of an inch: many had seen this print, but not one had detected the double image.

Mr. Wardley called attention to the now accomplished fact, that dry plates had been obtained by Dr. Hill Norris equal in rapidity to wet collodion in the camera. This was a great step in advance. Dr. Norris had patented the process, he understood. There was a long and animated discussion on the mode of gaining increased sensitiveness, and several members gave the mode of manipulation they employed; but none appeared to have any knowledge whereby they could produce plates so rapid as these appeared to be.

Mr. James Ward said he had great pleasure in reporting to the meeting that he had had great success with some plates he had prepared according to Messrs. Petschler and Mann's formula. He had exposed and developed several, and found them the best of any that he had yet tried.

It was resolved that the thanks of the meeting be given to the Chairman for his services, and for the address that he had delivered to the meeting.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VII. *(Continued.)*

ORNAMENTS, DRAPERY, ETC.—*Continued.*

White Satin.—French blue and ochre, with a touch of madder pink, forms the local wash; a little Indian yellow, ultramarine, and madder pink the half-tints; for lights, use white, with a very little blue and gum; and for the highest lights, strong full touches of thick perfectly pure white. As satin reflects the light, the tone, and colour of objects around very strongly, the shadows will display much variety of tint and depth. For the deeper shades use bistre, with a very small portion of French blue and madder pink. Having thus pointed out the pigments for the above, I need only remind the reader once again that further particulars on the subject of drapery may be found in Chapter VI. (No. 113).

Cloth is best treated with transparent and semi-transparent blacks, using body colour (white, black, and a little blue) for the high lights, and strengthening the deeper shadows with a little gum. In painting draperies your chief aim must always be to preserve the photograph. As a general rule warm shadows accompany cool lights: for instance, in painting blue drapery, use cobalt, or cobalt and white; for the high lights, French blue and lake for the shadows, and, for the deeper shades, madder brown.

Scarlet Cloth.—Commence this with a thin wash of carmine and cadmium carried over the whole; then use vermilion for the local colour; orange vermilion for the high lights; vermilion and lake for the half-tints; lake for the half-shadows; madder brown and carmine for the deeper shadows. To finish, work over the whole, excepting the deepest shadows, with the mixture of carmine and cadmium, thinly mixed with a very slight portion of gum.

CHAPTER VIII.

COLOURING IN OIL.

I know by letters received that some of my pupils have been anxiously looking forward to my promised instructions in painting photographs in oil. I hope I may be as explicit and useful as they desire me to be. I certainly think oil colours the more permanent when applied to photographs, and have good reason for believing that few water pigments remain long on such a surface without fading or changing more or less. With the most scrupulous care in choosing my pigments, and while conscientiously using none but colours of reputed permanence, I have found very few of my water-coloured photographs remain long in their original condition, and have found my own experience that of my professional friends also. The reader may have noticed the same fact in observing the specimens in water colours exhibited at the doors of photographic artists. I therefore recommend you to give attention to the lessons I am now about to commence.

It is frequently supposed that more skill and knowledge is required to colour in oil than in water; but, judging from the progress made by my own pupils in the one and the other, I think the idea altogether an erroneous one. A little may be done as easily in the one as in the other, and to do much will require about the same time, perseverance, and application. Oil colours are not, as is commonly supposed, more opaque than water, unless you use so little medium as to apply the colours on your surface with a most unnecessary and injurious degree of solidity and thickness. Before proceeding further it would be as well perhaps if I enter upon the explanations, &c., of a few terms, technically used by painters, in reference to oil painting.

GLAZING.

This is one of the most important of the oil painter's methods, inasmuch as effects are produced by glazing which cannot be emulated or equalled by any other process. It represents the most valuable feature in this branch of colouring. To glaze, you apply very thin films of transparent colours, for the purpose of modifying, altering, deepening, softening, or rendering more brilliant, as the case may be, colours already applied. By glazing you may render parts cool, or warm, strengthen or decrease effects, or soften and subdue

crude, hard masses of colour. Transparency can seldom be secured in a painting without its aid;—in its use it should be regarded more as a species of coloured varnish than anything else. The medium* with which you glaze should flow freely from the pencil, but not so freely as to spread beyond its intended limits; and the colours should be as transparent as possible, unless, as is sometimes the case, a glaze of semi-opaque colour is essential to the desired effect.

A glaze is best applied when the picture is just dry enough to prevent its being lost in the colours already on the surface: when the paint is too dry for glazing the colours will run off as water does from a greasy surface. When this is the case, the glazings will not prove so thoroughly permanent as they would if they formed a closer union with the colours beneath; but the glaze may be made to lie even and smooth, either by breathing on the picture, applying a little poppy oil and magilp, and then wiping it off, by using a few drops of alcohol with the colour, or by washing the part with a little alcohol and warm water. Glazing gives the whole picture a more natural, mellow, and subdued appearance, destroying in a great measure its painty effect. In glazing due attention must be given to the fact that the glazes are apt in time to assume a deeper and more yellowish tone than they have when first applied; some allowance should therefore be made for this fact in selecting your colours. For instance, in painting blues, they should partake rather of a purple tone than a greenish, because otherwise the oil in the pigment, turning yellow with time, must inevitably make the blue very green indeed, and so destroy your effect. For the same reason use as much varnish and as little oil as possible in glazing colours.

While urging upon your attention the really great importance and beauty of judiciously-applied glazings, you must yet understand that such are in a great measure dependent upon the painting over which they are placed, which should in its turn have been executed with due reference to their after application—the earlier colours being, with this view, lighter in tone and more opaque.

By way of hint, I may here add, that among the pictures of our great painters we find a judicious combination of solid and glazing colours best serve the purpose of permanency and lasting effect. For instance, Sir Joshua Reynolds, the beauty of whose flesh tints have been so enthusiastically praised, always depended upon his glazings. Sir Thomas Lawrence, on the contrary, seldom glazed at all. The changes undergone by the productions of both these painters are a common source of regret, while those of Vandyke, who combined "impasting" and glazing, are least affected by the test of time.

Some recent writers upon photographic colouring have, in their simplicity, argued that the photograph being perfect in light, shadow, and drawing, simple glazing would suffice to colour it. Without adverting to the thoroughly inartistic and unsatisfactory effect which would thus spoil a plain picture without making it a coloured one, I may tell you that such glazings would become discoloured and horny in a very few months.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

N. S.—The specimen is not a good subject to judge from; nor could I conscientiously hold out much hope of your ever becoming a professional photographic colourist. Try again, and let me see the result.

B, A. L.—The medium shall be tested, and the result announced if good.

* Or name given to the vehicle in which the colours are used.

Foreign Correspondence.

Paris, September 26, 1860.

Father Secchi, the director of the observatory of the Roman College, has just sent to the Academy of Sciences a new communication on the subject of the eclipse. I send it to you *in extenso*, because it throws into strong light the advantage of observations taken with the aid of photography, and at the same time refers to the labours of your fellow-countryman, Mr. Warren De la Rue. The Italian astronomer expresses himself thus:—

"I have little to add to what I have already indicated in foregoing communications; and, without repeating what I said in the first, I think it merely necessary to compare the photographs therein spoken of with those of Mr. De la Rue, taken near Miranda, at a station where the absolute instant of total obscurity preceded the arrival of the same phenomenon at the Desierto by about nine minutes of time. The only difference which exists is in the manner of counting the angles of position, which I reckoned from the apparent east to the apparent north, whereas Mr. De la Rue reckoned them from the true north to the true east. With this variation it will be found that *the positions* of the protuberances of our photographs are identical with those of Mr. De la Rue, except a slight difference of one or two degrees for those which are very small. This difference may be explained by the difficulty of taking angles in our little figures, which are but twenty-three millimètres in diameter, or possibly by a slight variation introduced at the moment of changing the camera, which perhaps was not fixed exactly to the mark that I had made on the tube of the glass. This little detail in nowise changes the fact of identity, and may have been produced by the change in the position of the moon relatively to the period of the local phase.

"I have fixed the first little photograph upon a sheet of white paper, and surrounded it with two graduations, according to the different manners of reckoning. In this manner the identity becomes apparent:—

Secchi	78°	113°	135°			198°	213°	242°	
De la Rue ...	197°	154°	135°	129°	111°	72°	57°	28°	348

"These are the only protuberances of which Mr. De la Rue gave a description in *The Times* of the 9th of August; and it will be seen from our photographs that he includes but the half of those which are noted down in our different pictures, and that in the third there appears others which are completely developed in the fourth and the fifth. The only essential difference I find between the micrometric angles and those deduced from the photograph is, that there is an error of 180° in two of them, due to my having taken the angle between the threads of the micrometer without turning the circle of position half round. I give the three series of angles thus rectified, and reckoned according to my method:—

"First photograph.—78°, 88°, 113°, from 135° to 148° a bright arc, 212°, 242°.

"Last photograph.—10°, 40°, 76°, 248°, 290°, 300°, from 350° to 306° a bright arc.

"Micrometric angle.—39°, 75°, 116°, 211°, 353°, 310°.

"It is clear, then, that if any observer saw fewer protuberances than I did the reason must be sought elsewhere. It is not improbable that it may be owing to some constitution of the eye, or rather to the great degree of attention given to one or two of the objects which causes us not to see the other. I can the more readily believe this, as a large protuberance (57° in Mr. De la Rue's reckoning, and 213° in mine), which was seen by so many observers, escaped my attention, occupied as I was in observing the others—113° and 135°.

"Thus, being much occupied with seeing the diffusion of light prevailing near the sun's edge, I did not observe these protuberances neither before or after the totality. I made fruitless efforts to see them in full sunlight; but I convinced myself that that would be impossible. I have almost a positive proof in the following fact:—Having one day, with M. Monserrat, taken an instantaneous photograph of the full sun, with a direct focus, merely opening and shutting the objective, we found the sun quite over-exposed, and the atmospheric region round the sun presenting a magnificent corona, tending to the same effect. We concluded from that that the light of the protuberances is at the utmost equal to that sent to us by the terrestrial atmosphere, illuminated by the full sun; consequently the protuberances would be invisible while the atmosphere is illuminated by the full sunlight.

"Although very small, the pictures show the double summit of Mr. De la Rue's protuberance of 28°, and the inclination of the protuberance of 57°, the great arc between 129° and 135°, &c. In fact, it appears to me proved that the objects photographed at Miranda and at the Desierto are evidently the same. This proves, also, what care should be employed on another occasion to take photographic pictures, but enlarged ones, for I am sure also that their printing would be very rapid.

"The principal deduction to be drawn from the photographs of the photographs of the partial phases (with a diameter of 106 millimètres) is the same that I was led to in 1851, namely, that the border is exceedingly feeble in comparison with the centre. One would say, on examining these pictures towards the sun's border, that the collodionised plate was not in the focus, so great is the diffuseness of the border; but the moon's edge is there, and shows that this diffuseness is not caused so, but by the real indecision of the sun.

"In several of these photographs there is the spot with its

penumbra well marked, and it is clearly seen that the sun's border is much less brilliant than even the penumbra of this spot. I hope soon to be able to send to the Academy some photographs of this kind. Thus these observations confirm the results which I have always maintained before the Academy for the last nine years, and which my thermometric labours upon the measurement of solar radiations had already put beyond a doubt. I have just made a comparison between the absorption of the terrestrial atmosphere obtained by observation and that given by the theory of Laplace, and I find that the theory does not represent the facts. I defer details to another occasion."

M. Zollner, following the indications given by M. Niepce de Saint Victor, has made some interesting experiments on the salts of uranium and on those of iron. By plunging a sheet of paper into a bath of pernitrate of uranium, and then spreading it upon a weak solution of starch, he has obtained, on contact with the sunlight, a picture which he fixes by simply washing. His studies on the salts of iron have led him to a photographic printing process, which is thus summed up:—A sheet of paper covered with starch is floated in the dark, during from thirty to sixty seconds, on a bath composed of—

Solution of perchloride of iron	1 part by measure.
Concentrated solution of peroxalate of iron	6 parts.
Distilled water	14 „

In drying, the paper takes a yellow colour. When completely dry it is placed in the pressure-frame. Three minutes' exposure to the light is more than sufficient. It is washed with a solution of iodide of potassium in albumen (two or three grammes of iodide to the white of three eggs), then washed copiously on both sides with common water, and dried between sheets of blotting-paper. During the washing the colour of the picture is observed to change from light brown to dark blue.

I see, from the interesting labours referred to in the late numbers of the BRITISH JOURNAL OF PHOTOGRAPHY, that the important question of "dry collodion" is still actively occupying attention in England, and that the processes recently made public by your investigators tend to the simplification of the methods hitherto known. This question has also for some time past been the object of serious study in France. You are acquainted with the process proposed by Mons. M. A. Gaudin. I have just received a letter from M. Vernier, in which, while he expresses a different opinion from that put forward by our able chemist, he agrees with him in deciding for the suppression of all preservative coatings. He recommends that the collodionised glass be left for at least four or six minutes in the first silver bath. He also advises that the glasses be submitted to a washing bath sufficiently acid to neutralise the fatty bodies, and to open the pores of the collodion. After exposure he plunges the plate into a second silver bath containing a twentieth of alcohol: in this it remains ten minutes at least. For developing he pours over the plate a solution of protosulphate of iron, to which has been added ether and alcohol at ten per cent. to facilitate imbibition. For this process to be fully successful, M. Vernier recommends that the collodion be powdery, short-fibred, and composed of ether and alcohol in equal proportions.

In a few days the French Society of Photography will resume its meeting; and shortly our amateurs and artists will be returning laden, I hope, with an abundant harvest of new works, and will supply me, I doubt not, with more important matters to communicate.

ERNEST LACAN.

New Books.

Ideal Views of the Primitive World, in its Geological and Palæontological Phases. By Dr. F. UNGER, of Vienna.

Edited by SAMUEL HIGHLEY, F.G.S., F.C.S., &c.

Late Lecturer on Medical Mineralogy at the St. George's School of Medicine, Grosvenor Place, London.

Illustrated by 17 Photographic Plates, from Drawings by J. KUWASSEG.

WE presume that, in the present day, few persons of education can be found who will question the superior advantages enjoyed by the students of our own time, in nearly every branch of instructional literature. Not only is the *art of teaching* recognised and understood as an important acquirement, but its rules are reduced to the exactness of a science. Amongst the many invaluable aids to the clear and comprehensive communications of knowledge we may certainly reckon that of pictorial illustration as one of the more useful kind, especially as it has within the last quarter of a century advanced in position from a scarce luxury to that of a civilised necessity, while its excellence has kept pace with its increased popularity, and in an inverse ratio to that of its cost.

There is, perhaps, no class of ideas more difficult for the uninitiated to realise by mere reading than the stupendous inductive discoveries of geological and palæontological science; and Dr. Unger has, in publishing his ideal views of the primitive world, conferred a boon, not only on the students in these sciences, but also on the general public, by offering instructive and pleasing materials for thought, divested of all "dryness," or compulsory acquirement of technicalities for their proper comprehension.

If Mr. Highley has played a more humble part in his capacity of translator, he has performed a no less useful one, so far as the British public are concerned, in placing before them a perfect transcript of the original work, though upon a smaller scale, and consequently at less cost—in which, by the aid of photography, every stroke and detail of the beautiful illustrations are faithfully pourtrayed; and thus the artist and his English admirers are brought, as it were, almost face to face. The photographic illustrations are from the *atelier* of Mr. Russell Sedgfield, whose name is a sufficient guarantee of excellence; and the subjects themselves, far from being the mere diagramatic sketches which we are apt to associate in our minds with geological illustrations, are, on the contrary, poetical, pictorial works of art of no mean order, pleasing even when viewed as isolated specimens, still more so when regarded as a series, and to which a perusal of the descriptive letterpress adds an additional charm.

Mr. Waterhouse Hawkins, we are informed, remodelled expressly for this work miniature copies of his "extinct animals," which form so prominent a feature in the grounds of the Crystal Palace at Sydenham, and a photograph of the same forms an appropriate frontispiece.

The following is a complete list of the photographs, of which there are seventeen, viz.:—

FRONTISPIECE—Restoration of the Extinct Animals of the Secondary Formation by Mr. Waterhouse Hawkins.

IDEAL VIEWS
of

I.	Transition Period	VIII.	Lias and Oolite Period.
I A.	Silurian Period.	IX.	Wealden Period.
B.	Devonian Period.	X.	Chalk Period.
II. & III.	Carboniferous Period.	XI.	Eocene Period.
IV.	Permian Period.	XII.	Miocene Period.
V.	Trias Period.	XIII.	Diluvium Period.
VI.	Muschelkalk Period.	XIV.	Alluvium Period.
VII.	Keuper Period.		

The work is of a convenient quarto size, well printed upon good paper, neatly bound, and forms an elegant ornament for the drawing-room table.

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

FAULTS IN TONING.

To the EDITOR.

SIR,—In toning positive prints I frequently find that, although nearly the whole of the proof colours beautifully in a few minutes, there are patches upon which the toning-bath appears to make no impression for several hours; and I need scarcely say that by this time the positive is entirely spoiled. I now use M. Lyte's bath, but I have often had the same difficulty with others, and with various kinds of albumenised paper.

If you can suggest the cause and remedy you will very greatly oblige.

I am, yours, &c., AMATEUR.

P.S.—The enclosed scrap will illustrate my meaning.

[An explanation of your difficulty may probably appear in the series of articles now in course of publication in this Journal, by Mr. C. Jabez Hughes.

Provided that you immerse but one print at a time in your toning-bath we think that there can be no doubt that the fault lies with the albumen: if several prints be put in the same bath together, contact of the papers would prevent the proper action taking place. It strikes us as possible that the fault may be owing to a slight *greasiness* of surface in the part that remains uncoloured, which would prevent the actual contact of the gold solution until the paper had become thoroughly saturated. To test this point we would suggest that, on the next occasion when you perceive symptoms of its appearance, you should immediately remove the print from the solution, press it between blotting-paper, dry it thoroughly, and then, with a tuft of cotton wool dipped in ether, pass it over the part affected so as to remove any grease that may be present; after which it ought to tone readily, if our conjecture be well founded. —ED.]

A WORD FOR THE OLD TAUPENOT PROCESS.

To the EDITOR.

SIR,—I think any one who has tried all the modifications of the Taupenôt process, which are many and wonderful—namely, salting the plate; using common albumen, *vice* iodised ditto, in disgrace; sensitising

with water, &c.—must be charmed, indeed, when he returns to his first love—the old original process, as preached by Mr. Mudd. All these new lights appear to me to do away with the chief advantage of the old plan, namely, the power of cleaning the plate during development with a piece of cotton wool. Besides which the inventors of these wonders almost always confine themselves to *stereo. pictures*, generally transparencies, which they exhibit at the meetings of their societies, and they are pronounced "particularly clear and bright." Why don't they produce a dozen 11 × 9 negatives? That would be some proof of the excellence of their discovery. Stereo. negatives and positives prove very little; for it has been already shown by the ablest photographers of this town that raspberry syrup, or gin and water, are all that can be desired for that *small kind* of photography: the latter for choice. Of course, the sooner a quicker process is brought out the better; but, till that is so, don't let the old *top-knot* (as some people call it) be run down. A day or two since, after a total failure with six wet plates, I prepared a few "top-knots," which developed as clear and bright as a plate could do. I used the same bath and the same collodion as I had used a few minutes before for the wet process. People say—"How about the blisters?" If they will only keep their *collodion thin, and their room and glasses warm*, I will warrant them against that misfortune.—I am, yours, &c., H. M.

Manchester, September, 1860.

P.S.—I ought to have said that these plates were 11 × 9.

[We have seen many dozens of plates 10 × 8, by several of the modifications of the Fothergill process, which will not, however, bear the rough usage that may be applied to the original Taupenôt plates. But what objection has our correspondent to Messrs. Petschler and Mann's method? That will bear equally rough usage.—Ed.]

CHLORIDED ALBUMEN FOR FOTHERGILL'S PROCESS.

To the Editor.

Sir,—Permit me to recommend the disciples of Fothergill to employ *chlorided albumen* in the preparation of their plates; for by so doing they will obtain increased sensitiveness, clean, bright development, and satisfactory density in the skies. In my experiments I have used four grains chloride of sodium, four minims liq. ammonia, one ounce pure albumen, and three ounces distilled water. The final washing must be *thoroughly* done.—I am, yours, &c., ALEX. NICHOLSON.

[If our correspondent will turn to our last volume he will find that there is not the slightest novelty in his suggestion, and that the practice he recommends has been *in use* for upwards of twelve months. We insert his letter, however, as opening up a question again upon which our experience is diametrically opposed to his own in one particular. Some increase of sensitiveness takes place, but not much. The density of the result, however, has in our hands been enormously *reduced* when a chloride has been used in the albumen. We shall be glad to record the experience of other operators on this point, as it is one of considerable importance, especially now that we are likely to follow the lead of Messrs. Petschler and Mann.—Ed.]

FOTHERGILL PROCESS.

To the Editor.

Sir,—I wish you to look at the enclosed print, and tell me what is the fault with the negative. I am but a new beginner in the Fothergill process, and it is doubtful if I get a better picture than this. The way that I make the plates ready is the following:—I coat the plate with Keene's collodion, and let it stay in the bath from three to four minutes. I then take it out, let it drain, and wipe the back, and then I pour on at one corner about two ounces of common tap water; but I find great difficulty in getting it to flow all over. I then take the albumen (I make the albumen this way: one ounce white of egg to three ounces of water, two grains of phosphate of soda, and ten drops of liquor ammonia), and coat the plate with this, and run it round for about six times, and then place it in a dish of water, and agitate it for about a minute; place it in another dish of water, and leave it till I have coated a plate for the bath. I then shake the first plate about for at least one minute, take it out and rear it up for about half-an-hour, and then dry by the fire. The enclosed was exposed for six minutes in sunshine, and developed with two grains of pyrogallic to one ounce of water, one drachm of common acetic acid, and six drops of silver solution. My lens is fourteen-inch focus and half-inch stop—one of Ross's. I cannot get any body or density in the sky. The other parts are very fairly brought out; but, taking it all together, it is very weak. If you would oblige me with your opinion of the cause, I shall be greatly obliged. I have tried one of the collodio-albumen plates; but I think I wash too much in the first water, for I cannot get the slightest picture.—I am, yours, &c., JOHN WEST.

[The portion of the positive proof received is *very* badly printed; and, although the negative is evidently weak, it would unquestionably yield a better result if properly used. You would probably succeed better by developing more slowly with gallic instead of with pyrogallic acid, and no acetic acid. You should not use common, but distilled water for your first washing; and with a little dexterity you could cover the plate easily enough with two ounces. After the addition of the albumen allow it to remain in a horizontal position for about one minute, and then wash off by a stream of water under a tap: you cannot do this too copiously. We believe that your chief fault lies in too little development as far as the negative is concerned, and very inferior printing aggravates the failings. In the ordinary collodio-albumen process it is impossible to wash too much in the first water. You may even use uniodised collodion.—Ed.]

ANSWERS TO CORRESPONDENTS.

Robert Lane.—Not till November.

Carker.—The quantities given are quite correct.

Amateur (Lewes).—1. See note to letter from "Alex. Nicholson." 2. See our No. for 15th August last.

D.—See reply to "F. B." In what the trick consists we are not aware, but that it is a trick there can be no doubt.

R. S. P.—We should recommend a trial of Messrs. Petschler and Mann's process as admirably suited to your requirements.

B. C. A.—Moist oxide of silver, added gradually if too acid; dilute nitric acid in the same way, if alkaline.

Charles S.—See notice in the present number. For the other localities named, you should get them from Mr. Wilson, of Aberdeen.

John Warry.—We are pleased to learn that you have profited by the hints given. We have no doubt that practice will make you a good photographer.

Adolphus.—Mr. Ross will no doubt supply what you require. We do not agree in the notion that a gas stove requires no piping, and would on no account use one without.

E. Eastwood.—We are unable to inform you of any means by which you can mould carbon into cylinders for Bunsen's batteries. We believe that hydraulic pressure is required.

Green.—Get a bi-lens camera, decidedly, having a pair of good single lenses, which are less costly than portrait combinations, and will answer your present purpose as well or better.

A. G.—We do not think that there would be any danger to your *chemicals* by burning charcoal in your stove; but, without very careful ventilation, it would be highly injurious to your health.

C. D.—Focus on your *principal* object, whether it be near or distant: the others are only accessories, and therefore may be more appropriately sacrificed, if any sacrifice be needed. You may perhaps be able, by management, to "humour" the subject a little.

Messrs. Hope and Co.—Had our correspondents' communication been sent to the editor instead of to the publisher, agreeably with the standing notice below, it would have received attention in the present number. As it is, it has reached the editor too late, and must therefore remain over till our next.

G. M. Redaway.—We cannot reply to any but private friends except through the medium of the Journal: our work would never be ended if we were to do so. Consult a paper by Mr. Hughes, published in No. 113, page 61, of the current volume. Act upon that, or use Maxwell Lyte's toning bath.

F. Graham.—From your description we judge that your collodion is somewhat deficient in pyroxyline: add a little more, say one grain to each ounce, and try again. You need not increase the quantity of your iodiser, as you will find that a thicker film will cause a more creamy deposit of iodide of silver.

F. B.—1. We do not think that varnished negatives will be injured if kept in a deal box, provided it be dry. 2. You can dry your plates in an unvarnished tin box, and, provided the varnish be thoroughly dry, we do not perceive how any vapour could arise therefrom. 3. The advertisement to which you allude is, of course, a trick.

Anxious Artist.—Our conjecture was correct: we find that they are studies taken at Ryde. The same operator has also some others of a similar character that are, in our opinion, still finer than those you pointed out. Apply to him direct, stating for what you require them, and we have no doubt that you will obtain well-selected copies.

J. H. Slater.—The toning bath which your friend proposes would do the work well and quickly, no doubt,—but at what a cost! each print would cost you five shillings, at least, in toning! If you want to try another than that you now employ let it be Maxwell Lyte's, which you will find in Volume VI., page 67, of this Journal.

A. H. B.—If you will consult a paper by Mr. C. Jabez Hughes, in No. 113, page 61, of the present volume, and follow the instructions there given, you cannot fail to attain your object. Toning with the old hypo. bath is radically wrong in principle; and, with albumenised paper, fading is merely a question of time.

Nemo.—The difference consists in the fact, that in Messrs. Petschler and Mann's process the plate after being prepared is insensitive to light, but becomes sensitive by merely washing away the superfluous *chloride*; as the albumen has become coagulated by heat, that is *not* washed away at all. You would gain nothing in sensitiveness by the course you propose.

R. J——s.—Your enquiry betrays either gross ignorance or insolence. Can you point to any single instance in which we have awarded undeserved commendation? We may err in judgment, as no man is infallible; but at least you should have learnt, had you been in the habit of reading this Journal, that we never sacrifice independence, or truth, to interest. Your specimens are returned, and we decline any further communication.

W. Anderson.—We are unable to inform you of the composition of the fluid contained in one of Mr. Archer's fluid lenses: it is by no means improbable that filtering it would clean it. We have seen an advertisement occasionally put forth by somebody resident at Poplar, who acted as agent to Mrs. Archer, after her husband's death, and who was formerly employed by him we believe. It is possible that he would undertake to restore your lens.

C. B.—We consider that the *best* stove for a photographic room is one of Arnott's, in which anthracite coal is burned, as it requires filling but once a day, makes neither dust or smoke, and keeps at one uniform temperature. We see no objection to the long pipes passing through the dark room, if convenient. We are not acquainted with the merits or faults of the terra-cotta stove. We have seen a kind of gas stove that would be very applicable for the purpose of warming a photographer's room, but we question its economy.

R. T. D. (a Novice.)—The defect you are puzzled with is known by the term "measly spots," and arises from too weak a solution of hyposulphite of soda, or, what amounts to the same thing, a state of circumstances that prevents the immediate action of the solvent on the chloride of silver. You should not let the strength of your sensitising bath fall below 60 grains to the ounce of water, and do not let it be more than faintly acid. After removal from your toning bath wash in plain water, and do *not* immerse the proofs in the solution of hyposulphite of soda while saturated with moisture, but hang them up to drip, and when nearly surface dry, fix them. If immersed while very wet, even in a strong solution of hyposulphite of soda, the portion in immediate contact with the paper becomes much diluted—hence the fault complained of. You had much better not use the *sel d'or*, but get your photographic chemist to exchange it for an equivalent value of chloride of gold. One out of the three proofs received is very good.

⁂ Several correspondents who made inquiries some time back for stereographs of English lake scenery are referred to our notice of same in the present issue.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 128, Vol. VII.—OCTOBER 15, 1860.

If we ever had to exercise the office of a judge in sentencing a convicted literary culprit to adequate punishment, we should certainly prescribe an unrelenting course of compulsory reading in BLUE BOOKS. Of course it is scarcely necessary to state that we mean especially those issued by authority of the House of Commons. It is generally supposed that the designation "blue books," by which these publications are *distinguished,* is owing to the colour of the covers in which they invariably appear; but this must be a mistake, and we are satisfied that it arises rather from the condition of those who are obliged to peruse them (it cannot be that anyone but a lunatic would voluntarily do so)—an operation which inevitably induces a "fit of the blues." We assert this from experience. We have recently had an attack of the kind, which has only been brought to an issue by the storm of indignation which was raised within us after a careful perusal of the Report of the Committee of the South Kensington Museum, and the evidence upon which the Report is alleged to have been founded. For anything that we can perceive to the contrary, the report might just as well, indeed better, have been written without hearing the evidence; as in that case the discrepancy between the two would not have been apparent. We came to the inquiry in a perfectly dispassionate frame of mind. We have no personal interest in the question, either one way or other. We had formed no opinion upon its merits; and if a bias in either direction had found a place in our mind, it would probably rather have tended towards the side of the Department of Science and Art—partly on account of our feeling an inclination, like most other people, to be supplied with marvellously cheap copies of the works of the old masters, and partly because an indignity had been cast upon both the scientific and art aspects of photography by the principal antagonist of the "Department," in designating mere copying "one of its highest branches." Our appreciation of the attempted indignity we have already recorded at page 263, and we see no reason to alter the opinion then expressed; but we cannot allow the error of the advocate to prejudice our judgment of the case, to the investigation of which we have devoted a considerable amount of time and patience We have gradually and deliberately arrived at the conclusion that the authorities of the Department of Science and Art, at South Kensington, have been guilty of a great injustice, to seek to rectify which we can conscientiously affirm is well worthy the strenuous exertions of photographers in general. It is true that the number of individuals directly interested is but small in the present instance, but that does not affect the fact that injustice has been committed. What is the case of one class to-day may be that of another to-morrow. The thin end of the wedge has been inserted: let photographers bestir themselves or they may find the wedge driven home before they are aware of it.

In order that the following observations may be intelligible to our readers, we must beg the favour of their re-perusing Section 12 of the "Report," which we reproduced a few numbers back, as will be seen on reference to page 257 of the current volume. It will also probably be remembered that, about the middle of last year, an announcement was made relative to the intention of supplying the public at large with positive photographic copies of works of art, at certain rates, from the government establishment at South Kensington.

It is found that this announcement, though scarcely yet carried into effect, has seriously injured a commercial speculation of one professional photographic firm. It is feared, with just grounds, that others also will suffer; and, furthermore, there is no security that the existing interference with private enterprise may not be carried to a still further oppressive extent.

We will endeavour to put the case clearly and succinctly before our readers:—

1. It has been assumed that there exists an extensive demand on behalf of the public for cheap photographic copies of works of art, and that in order to promote art education this demand should not be checked.

2. Photographic reproductions from public collections at home and abroad having been made by the "Department" to furnish models for the use of the schools of art, it has been arranged to supply the general public also with positive copies at (what is alleged to be) *cost price.*

3. It is asserted that, owing to objections on behalf of the trustees of public collections, it is *impossible* for the public to procure photographic copies by the agency of private enterprise, and that *as there must be monopoly somewhere* it is better that it should be in the hands of a government body.

4. A parallel case is assumed to exist in the official publication of parliamentary papers.

There are several other minor points which it is not necessary to particularise at present, but which will be noticed incidentally as we proceed with the argument.

In the first of these four propositions we fully concur—we have not a word to say against it; but, with respect to the other three, we entirely deny their policy or soundness, and affirm that they are in direct contradiction to the weight of evidence published with the "Report" itself.

There is an extensive demand for cheap photographs of a particular kind, which demand it is highly desirable should be supplied. The same may be correctly said of cheap bread, meat, and clothing. It is regarded as injurious and unjust for the government authorities to attempt to interfere with private enterprise in supplying the three last-named articles. In what respect does the other one differ? The reply is the third proposition above given. But, on reference to the evidence, we find that this reply is quite untenable.

It is proved that Signor Caldesi did obtain permission to photograph the Cartoons of Raffaelle at Hampton Court before any similar application to the Board of Works was made by the South Kensington authorities; and, furthermore, that he succeeded in maintaining his right to avail himself of the permission *in spite of the most determined opposition* on the part of the "Department."

It is proved, by the evidence of Mr. Fenton, that permission to photograph in the British Museum was readily accorded to competent operators — *until, by the interference of the "Department of Science and Art*," such permission was withdrawn.

It is proved, by the evidence of Mr. Scott, that permission has been granted to his firm to photograph pictures in the Royal Collection, which Mr. Redgrave declares has been granted *exclusively* to the official photographer of the "Department."

What do we find, then? That the difficulties existing are only such as have been interposed by the "Department" itself, which then quietly asserts that it is *impossible* for private individuals to procure the requisite facilities!

It is generally held that it is next to impossible to prove a negative, yet the "Report" attributes the execution of this clever feat to Mr. Redgrave; for we find it stated that "Mr. Redgrave proved that Messrs. Caldesi & Co. would have been unable to have produced any satisfactory photographs unless the Department had permitted them to have the benefit (?) of the removal of the Cartoons by their [its ?] officer."

Irrespective of the ambiguity of the adjective "satisfactory" there is in the above paragraph an assertion in direct contradiction to the evidence. Mr. Redgrave holds a double office, as he himself pointed out, viz., that of Surveyor of Crown Pictures, as well as being an officer of the Department of Science and Art; and it was in the former capacity that he superintended the removal of the Cartoons in obedience to a mandate from the First Commissioner of Works, in compliance with a promise given by that minister to Signor Caldesi: therefore the compiler of the "Report" has committed an error of no little importance (to call it by no harsher name) in stating that the officer of the Department, "as such," had anything to do with the removal of the pictures.

Passing by, for the moment, the question of the justice of supplying the public with positive copies at *cost price*, we would draw attention to the fact, that the amount paid simply for materials and labour for the positive only is *not cost price*, nothing being charged for the negatives, either as regards materials, labour, plant for producing them, or rent of premises; and we have no hesitation in asserting that the scale of prices published is unquestionably below the cost, especially as respects large pictures. What can be more absurd than to make a fixed rate at per twenty square inches of surface without reference to the dimensions? Every practical operator is aware that there are comparatively but few sheets of paper fit for large work, in consequence of flaws and specks of various kinds, though, for small work, the defects can be avoided by judiciously cutting up the sheet. This is, however, nothing in comparison with the extra labour demanded in manipulating large sheets and extra risk of damage to them; for a large sheet of paper, when saturated with moisture, requires very careful handling to avoid its being torn, even by its own weight, and consequently more time and skill than is sufficient for the same quantity of surface in small pieces.

While on this part of our subject, we cannot forbear remarking upon another statement in the "Report" which betrays the most extraordinary ignorance of commercial matters in the compiler. We quote the passage to which we allude, viz.—"That, as the sale of the Cartoons by the Department cannot yet be said to be in operation, the apprehension of being undersold is at least premature." And this in the face of the fact that the *scale of prices* at which the "Department" undertakes to supply copies was published as long back as the month of May, 1859, the prices being professedly only cost prices, but in reality much below cost! To our intelligent readers further comment on this point is needless.

In the evidence of Mr. Redgrave much stress is laid on the fact that the Government photographer is bound to produce for the public negatives of any object in the collections at South Kensington and the British Museum at the fixed rate of threepence per square inch, and argues that it would be, consequently, quite unnecessary for private operators to take negatives, even if they had ready access to the originals for that purpose. It is not very likely that any photographer of eminence would publish proofs from a negative obtained in the manner suggested; but, even if there were no scruple on that point, what security would he have that the "Department" would not immediately have another and possibly superior negative taken of the same object, from which copies might be supplied to the public *at cost price*, and thus the private dealer would be undersold, even if the real, and not the assumed, cost price were that charged?

It is nothing to the purpose that the present official photographer is a gentleman whose integrity is above suspicion: he is bound to obey the behests of his employer.

A parallel case is assumed between the sale of photographs and the sale of parliamentary papers; but the slightest examination of the subject exposes the sophistry of such argument. The former are eagerly sought for as matters of luxury — the latter are only in demand in consequence of a stern necessity. The copyright of parliamentary papers is vested in the government; but, if we are not mistaken, absolute freedom is granted to anyone to reprint the whole or any part of the documents coming under this designation. They must of necessity be printed for the use of members, and as no private printer would think of producing them, because they would be unremunerative, no injury is inflicted on the trade by their sale.

It is argued, in justification of the sale of photographs at cost price by the South Kensington authorities, that it is not right to surcharge the public for *the use of its own property;* but, in the same breath, it is enunciated that a portion of this same public should *not* be allowed the free use of its own property in photographing it! Surely the same fountain is putting forth sweet water and bitter.

This same pretended care for the public is a most plausible pretext, but it is in fact very unfair. What though those interested in the sale of photographs do suffer by making the South Kensington Museum a commercial establishment in competition with them, at which the products are sold at cost of labour and materials, without any charge for rent, implements, and profit? Does not the public supply all these, and ought it not to receive the benefit? Truly, the public does supply these; that is, the whole public — professional photographers included—and that by compulsion. But the whole public does *not* receive the benefit of the low prices, nor anything like the whole, not even a majority, but simply a very small fraction of the whole. Why, then, should all be taxed for the exclusive benefit of the few? but, especially, why should photographers be constrained to contribute funds for the destruction of their own business?

This turning of a government department into a mere trading establishment is a monstrous evil, and should not be tolerated for one moment. By leaving the matter unheeded because photographic publishers are few in number we allow a most vicious principle to become established as a precedent; and, sooner or later, others besides photographers will surely suffer for it. We counsel those who are more immediately interested in the matter at once to prepare a memorial on the subject, addressed to the Lords of Her Majesty's Treasury, who, we believe, have the power of putting an immediate stop to the proceeding. We have little doubt that such a memorial would be speedily and numerously signed, not only by photographers, but by others; for though we all like to obtain cheap works of art, let us hope that the majority amongst us like justice better.

It must not be forgotten that, in the first instance, the "Department" sought for and obtained permission to copy the Cartoons *solely* for the use of the art schools in connexion with it; and that it is by no means clear that if the intention of competing with private enterprise in supplying the public had been known to the First Commissioner of Works at the time of

the application for permission to take the photographic copies—it is not very clear, we assert, that any permission would have been granted. This may or may not have been the case, but at any rate we find no record of any sanction having been sought for this public trading proceeding.

We have, however, no idea that an abrupt termination to the trading eccentricities of the Department of Science and Art, need in any way interfere with the public in obtaining photographic copies of works of art at reasonably moderate rates, nor that any special difficulty exists in making regulations for private photographers having access to the pictures in public collections without any greater inconvenience than is experienced under the system at present in operation. We suggest the following outline of a plan that we believe would be found to work satisfactorily:—

Let us presume that application is made for permission to copy one of the pictures in the National Collection. Let the application be of necessity accompanied by an undertaking to supply the public with copies at such maximum rate as the applicant may think sufficiently remunerative for his undertaking. Before granting the permission sought let a public notice be issued, by advertisement or otherwise, announcing all the particulars of the intended scheme, *except name and price*, and appointing a certain day on which tenders would be received from others to execute the same undertaking. Should there be no other applicants, or none offering to fulfil the conditions on terms materially lower than the first proposers, then the originators of the idea to obtain the privilege; but if there be others undertaking to perform the same work on considerably better terms for the public, the original applicants to be offered the option of accepting the lower terms, in consideration of their having first started the idea, and if declined, then those who offered the lowest terms to obtain the privilege. Security might be required for the due performance of the contract in either case, as well as for repayment to the government of all expenses incurred in performing the operation of photographing.

If some such scheme as that we have sketched were put in force we believe that the public would obtain such copies as might be in demand at fair and reasonable rates. If any demand existed, it would pay photographers to supply it: if under such a system it would not pay, we think it would only be just to conclude that the demand did not exist. It may be noticed that we have proposed no provision for testing the competency of parties applying. We have purposely omitted it as an entirely needless precaution. No copy could be taken without incurring much labour and expense, and, consequently, nobody would be likely to undertake it without a reasonable expectation of fair remuneration; and this of itself involves the requisite skill.

We have discussed this question at some considerable length, because we believe it to be one of serious importance to the photographic profession—not affecting the art and science of photography, but its application, which is a very different affair. It is a question which must sooner or later interfere materially with the commercial branch of photography; and it is our firm conviction that, unless an immediate and determined opposition be at once set on foot against the practice that has been so unwarrantably organised, photographers will, ere long, see cause seriously to deplore their want of energy and foresight.

We regret to notice that we are about to lose the services of Mr. Edward Mann as Honorary Secretary to the Manchester Photographic Society, an office which he has very ably filled during the past two years. Indeed all our readers will, we are convinced, cordially join in the vote of thanks which has been accorded to him by the members of the society, of which he has proved himself a most useful officer,—as they (our readers) have participated largely in the result of his labours.

Our regret at Mr Mann's retirement is, however, somewhat balanced by the pleasure we feel in finding that as a successor he is to be replaced by Mr. W. T. Mabley, an enthusiastic photographer and a careful observer—a gentleman whose name will be familiar to our readers as the author of an excellent article, published a short time back, *On the Theory of Positive Printing*. It has been sarcastically observed, that gratitude is an expression of expectation of favours yet to come. Certainly Mr. Mabley has already earned the *gratitude* of photographers, both in the direct and in the perverted meaning of the word.

KNAVERY.

There is a very apt saying—"Hypocrisy is the homage that vice pays to virtue;" and another—"Imitation is the sincerest flattery." The counterfeit bank-note affords testimony to the value of the real one, though the method of so doing is by no means commendable: in like manner the spurious manufacture testifies to the excellence of the genuine article.

We have been led to these remarks by a communication just received from Mr. Ross, the celebrated optician, by which we learn that his well-earned reputation is in danger of suffering severely from the nefarious proceedings of some unscrupulous individual, who it appears has been putting into circulation some spurious and worthless photographic lenses to which the name of the late Mr. Andrew Ross has been attached. We assert that Mr. T. Ross (the son) is threatened with damage to his reputation by this proceeding, because it is notorious that the production of photographic lenses was entirely under his superintendence during the lifetime of his father; and it is questionable whether any were ever issued from the establishment without passing through the hands of Mr. Thomas Ross. The discovery of the fraud arose in consequence of a lens, purporting to be of Mr. Ross's manufacture, having been offered at a pawnbroker's shop for the purpose of raising money thereon. The shopkeeper, knowing the commercial value attached to these instruments, applied to Mr. Ross to ascertain whether the lens which had been offered was genuine or not. Of course the fraud was instantly detected. We are informed also that several instances of the forged name having been applied to worthless lenses have come to light.

Under these circumstances, Mr. Ross has taken a very judicious step, although it will probably entail upon him a considerable amount of unremunerated labour—no less than that of undertaking to examine for verification *any lens* purporting to have been constructed at his establishment, whether purchased there directly or not. This will be a great boon to many who may be in possession of a "Ross" that has come into their hands indirectly, and we strongly advise all so situated to take advantage of the liberal offer.

While on the subject of fraud in connexion with photography, we solicit the attention of our professional friends to the following letter:—

CAUTION TO PHOTOGRAPHIC DEALERS, &c.

To the Editor.

Sir,—Some three or four months since a person calling himself *Professor* Kastner paid me a visit, showing me a printed circular signed by several gentlemen at Portsmouth, also photographs by Mr. Rejlander, which he stated he was selling for him, and photographs which were printed for him by Mr. Bedford. He wished to have a quantity of photographs of mine from the Dresden Gallery, and which, with the others he had, he said he could sell any quantity of. Believing his statements to be correct, I let him have nearly five pounds' worth. He went to Exeter, and wrote for over one hundred more. In the meantime I wrote to Mr. Bedford, and found he was indebted to him about ten pounds, which he was doubtful of receiving. Having sent several letters to him they were returned to me from Exeter, where, I found, after receiving the photographs from me he left, paying for three weeks' lodging six shillings only, promising to return in a couple of days. Thinking he might be serving others in the same way, I wrote to Mr. Rejlander, whose reply was:—"He has done me by false representations, &c., in a similar way." I then wrote to one of the gentlemen named in his circular, Mr. Thomas Vickery, Hope House Academy, Southsea, who stated, in reply, that he was for eighteen months a teacher in his school, but in April last he drew his quarter's salary in advance—fifteen pounds—and left in a few days; that he never expected to get it again; and also that Professor Kastner was *wanted* by others at Portsmouth. Mr. Wood, of the Abbey Hotel, in this

city, also informs me that he stated to him he was travelling for me, and he allowed him to run up a bill for one pound twelve shillings. On the Saturday, when he was absent, he went away, saying he should come back on the Monday, which I need hardly say he has not done, or remitted his account. I should not have written to you had this been a matter concerning myself; but finding he has been playing others the same trick, and doubtless is doing so in some other part, I think it quite time his "*little game*" was put a stop to; and I trust this will prevent any one else being served in a similar way. The said Professor Kastner is about five feet ten inches high, stout, and very restless in his movements.
—I am, yours, &c., HORATIO N. KING.

Photographic Depôt, 42½, *Milsom Street, Bath.*

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 13.

The discovery of Messrs. Petschler and Mann has now been before the public for several weeks, and we, in common with many others, have made trial of the modified process which they suggest. In describing the results of our experiments we shall presume the reader to be already acquainted with the contents of the paper recently read before the Manchester Society, and also with the discussion which followed it.

The first point to be ascertained was, how much of the albumen remained upon the film of iodide after the second washing.—Our theoretical anticipations were that the washing would remove the whole or the greater part of the albumen, inasmuch as the nitrate of silver solution ordinarily used for coagulating is omitted in the new method. Artificial heat was indeed spoken of as a means of producing coagulation of the albumen; but we think that it would not be prudent to place too much dependence upon heat applied by simply holding the plate to the fire, since it is difficult so to regulate the temperature as to ensure the coagulation. The plan we usually follow in dry collodion experiments is to rear the plates around the sides of a covered box, and to put a hot iron in the centre. In this way the glasses become warm, but never more so than the hand can easily bear. Messrs. Petschler and Mann's plates were therefore treated in that way, and subsequently washed in water until nothing further appeared to be extracted. The washing waters, when tested, were found to contain albumen; and an examination of the film appeared to show that it had lost a part, but not the whole, of its surface coating. The following simple plan is the one on which we now rely in testing the quantity of organic preservative left upon a film, and we shall be glad to hear whether some of "the old hands" in the dry methods have observed the same phenomenon:—Take a rather firm and contractile bromo-iodide collodion, and coat with the preservative after sensitising and washing. The resulting film, rather creamy whilst wet, becomes paler and more opaline on drying. Now, wet it a second time with water, and, if the organic preservative be abundant, it will regain its creaminess; but if it be deficient, it will remain blue. Thus a plate preserved by Norris's method will return to its original colour on wetting, whilst a Fothergill plate will not do so.

Having selected, therefore, one of the dried Petschler plates in the first stage of its preparation, we moistened it with water, and observed that the albumen expanded and the opacity of the film increased. After abundant washing, however, and a second desiccation of the plate, wetting with water produced comparatively little expansion or difference in colour. From this we inferred that the porosity of the collodion had not been fully maintained, but that it had contracted on drying, and would not again swell up as at first.

If the whole of the albumen does not remain upon the plate after the second washing in Messrs. Petschler and Mann's method, we must not expect that the developer will penetrate sufficiently to produce a very rapid action, nor that the negatives will bear as much cleaning with cotton wool as in the old Taupenot process.

The second point for consideration was, how far the plates are insensitive to light whilst the salt remains upon their surface.—We find that they are so far deficient in sensitiveness that they cannot be used for taking pictures in the camera, but that the operator must not presume to expose the plates to diffused daylight. In examining the films in this particular we determined to make the test as severe as possible, and therefore selected an old bromo-iodised collodion known to yield very intense images in the dry processes. A collodion of that kind, in passing through the bath, forms not only iodide and bromide of silver, but also, without doubt, some organic compound of silver in small quantity. To prevent a strong light from impressing such a film would therefore be more difficult than if organic combinations were absent. On twice trying the experiment we did not find that an excess of chloride of sodium had sufficient power to suspend the actinic effect under these circumstances; for the picture was fogged and imperfect in both cases, when the plate had seen the light in its early stage. It is possible that if, after having exposed the salted plate to diffused daylight, we had put it away for a time in the dark, the excess of chloride of sodium might gradually have discharged the latent impression. This, however, we omitted to do: the plate was washed and re-dried immediately after the first exposure, and a foggy camera-picture was the result. Alkaline chlorides are undoubtedly less active than alkaline iodides in discharging latent images. Some time since, whilst drawing up our report of M. Poitevin's method of producing transmitted positives, we found that, although a dilute solution of iodide of potassium, assisted by white light, instantly obliterated an actinic impression on the collodio-iodide of silver, a dilute solution of chloride of sodium did not do so. On removing the base, however, and employing free hydrochloric acid, instead of an alkaline chloride, the latent image at once disappeared.

Supposing we allow that the plates of Messrs. Petschler and Mann are not always absolutely insensitive in their first stage, yet we cannot but suppose that they are in a highly favourable condition for long keeping. The operator may prepare any quantity and take them with him on his journey, keeping the lid of the box closed as a precautionary measure.

The point which stands third and last for discussion is, the quality of negative which these plates yield.—Our impression at the present time is, that the negatives are all that can be desired, if the collodion be of the right kind; but that their quality will vary with the collodion more than in the old process of Taupenot. This we find, by experiment, to be the case; for, taking bromo-iodised collodion, as we have described it in this Journal, and working with it the day after iodising, we obtained an image rather wanting in contrast, and too grey and metallic in colour; yet, with the same kind of collodion, four months old, the depth and brilliancy of the negatives were very decided. It can scarcely be expected that a process in which the albumen is not coagulated by nitrate of silver can give the same security for intense development as the old Taupenot process, and hence more attention must be paid to the condition of the collodion. As regards the *sensitiveness* of the Petschler film we find no cause for complaint, since the shadows of the picture were well rendered by times of exposure certainly not greater, and perhaps somewhat less, than we are in the habit of giving for the Taupenot process.

To secure a second string to one's bow is proverbially useful, and the more the operator understands of the science the better will he be able to practise the art of photography. We are greatly indebted to Messrs. Petschler and Mann for showing us that when our aceto-nitrate bath gets out of order, and produces floating scum, marbled stains, or muddiness of development, we can for a time assert our independence, and set it aside altogether.

P.S.—Since writing the above we have prepared a Petschler plate with recently-mixed bromo-iodised collodion, and exposed it for twenty seconds to the diffused light of a room, the chloride of sodium being still in the film. In this case there was no action, and the camera-picture subsequently taken on the washed plate was free from fogging, although rather deficient in intensity.

ON A MODIFICATION OF THE COLLODIO-ALBUMEN PROCESS

By John Parry.

[Read at a Meeting of the Manchester Photographic Society, October 3, 1860.]

At our last meeting I read a short paper *On the Action of the Aceto-Nitrate Bath*, in which I endeavoured to show that its only use was the coagulation of the albumen on collodio-albumen plates. Since then I have pursued the subject a little further, and find that all we require is the coagulation of the albumen by the most convenient means. Pictures may be taken by coating the washed and sensitised collodion with gum, gelatine, &c., after removal from the usual thirty-grain bath; but all these processes have a tendency to blister more or less. The method I find to answer best is by simple immersion in hot water after the application of the albumen.

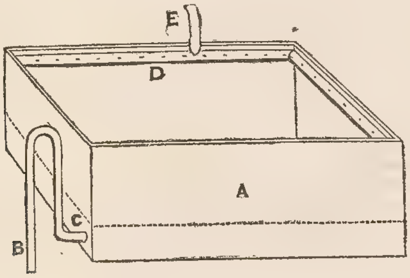
The plan I adopt is as follows:—I coat the plate in the usual manner with collodion; sensitise and wash, first in a large dish and afterwards under a tap; allow it to drain a minute or two, and

afterwards float over a solution of uniodised albumen, say one ounce of albumen to one ounce of water, and after draining a short time, but before it has time to set, immerse in a suitable vessel of very hot water, say for half a minute; dry the back of the plate with sponge, and set in a dark place to dry, when the plate is ready for use.

The conveniences of the above plan I find to be cleanliness of development and entire freedom from blisters.

NEW WASHING APPARATUS.

As I fancy the manner in which I wash my prints is better than many of the methods ordinarily adopted, and as it has been adopted by many of my practical photographic friends, I send a description of it for your pages, thinking that any information on a subject so important as washing proofs effectually would be welcome, particularly as the cost of this plan is at most a mere trifle, and, as it will be self-regulating, there is no danger of an overflow. The annexed drawing will serve to show the construction. It is an ordinary washing box, of any dimensions which may be most convenient, with a siphon attachment, which acts immediately on the water reaching the level of the top bend of the pipe; care should be taken to have the overflow or siphon of capacity to run the water off very fast, at least four times as fast as the feed—which may be done by increasing its size. A false bottom should be placed inside, slanting to the hole, that the deposit of dirt from the water or other matter may be drawn off; a network raised one inch from the bottom is indispensable, to keep the prints from getting into the pipe.



A, box of ordinary kind; B, siphon which is entered up through the bottom of the box at the corner C, and on which is a broad flange of lead, which is firmly tacked with copper nails to the bottom of the box; the siphon B is then carried up inside to be out of the way, to within about one inch of the top, then down as far as it may be desirable—it must be below the level of C; D is the feed pipe, the water coming in through pipe E and through D carried all round on the inside of the box, and perforated with small brad-awl holes. The water may be allowed to run in as fast or slow as may be wished—it matters not. The operation must be evident: as soon as the box A fills with water on a line level with the top bend of siphon B it must run out, and will in a few moments empty the box, leaving the prints lying on the network; the water running in all the while through pipe D, they soon float again, the box fills and again empties, and so on as long as the water runs. By this plan the water changes every ten minutes or every half hour, depending on supply, and changes thoroughly, no more water being used than in the old surface overflow style of box. This may not be new, but I fancy it is; however, it works to a charm. H.

ON IODIDE OF SILVER.

By Dr. J. Schnauss.

All who are sufficiently acquainted with chemistry and photography know that the former, notwithstanding its delicate apparatus and reagents, has not yet arrived at that stage of perfection in which it can satisfactorily explain every kind of photo-chemical process.

In this respect the observer will involuntarily remark an analogy between these processes and the combinations and decompositions that take place in the living organism of the animal and vegetable kingdoms.

The most deserving of notice is the still mysterious process for producing the *latent* photographic image. The principal source of this image, as is well known, is the film of iodide of silver, in combination with greater or less quantity of nitrate of silver. The complete washing off the nitrate of silver solution from the plate in the dry-collodion process is no exception to this rule; for it is impossible to neutralise the action of the iodide by washing it with clean water only. Here we arrive at a point which deserves to be mentioned in the annals of chemistry. It is this:—Photo-chemical researches long ago proved that there are two modifications of iodide of silver—one being sensitive to the light, the other quite insensitive; and there are also many other physical differences between the two kinds. In my researches on these modifications I proceeded in the following manner:—

I dissolved a given quantity of pure nitrate of silver in distilled water, and divided the solution into two equal parts, then added to each an equivalent of iodide of potassium dissolved in water. To one portion I then added a little more nitrate of silver, and to the other a little more iodide of potassium, and stirred the mixture well together. This operation, as well as the following experiments, were carried on out of the influence of daylight.

A remarkable difference was immediately discernable between the two deposits of iodide of silver. The one acted upon by nitrate of silver very quickly settled to the bottom of the glass vessel, and was of a beautiful light lemon colour; the other, treated with iodide of potassium, was a very bulky precipitate, increasing nearly three times in bulk during the process of washing, and nearly white in colour.

Both precipitates were repeatedly washed with distilled water, until a filtered portion of the washing was no longer clouded either by a solution of common salt or of nitrate of silver. This external difference between the two precipitates was permanent. I next exposed a portion of both to the influence of the solar rays. In a very short time the iodide of silver precipitated with the nitrate of silver changed to a brownish hue, while the other retained its yellowish white colour quite unchanged.

To distinguish these two modifications of iodide of silver, we will call that one which proved sensitive to light the + iodide of silver, and the other — iodide of silver.

Both were then submitted to the action of sulphate of iron, but they both remained unchanged, even the + iodide of silver did not assume a darker colour; but the addition of a few drops of nitrate of silver caused both modifications to turn black. Two other samples of iodide of silver, exposed to the light, and placed in contact with a solution of nitrate of silver, turned both grey.

From this it would naturally be supposed that an optical image thrown in the camera upon a film of — iodide of silver, and the collodioned plate then again dipped into the nitrate bath, would become visible under the action of the developer; but such is not the case.

I then made the following experiments:—

1. A sensitised collodion-plate was washed, upon one-half of its surface a dilute solution of iodide of potassium was poured, and the plate then washed again, taking care that the water did not flow off the iodided portion on to the other. The plate was then put into the silver bath again for a few minutes, and afterwards developed.

On that portion of the plate acted upon by the iodide of potassium scarcely any traces of a picture were visible; whereas on the other portion a picture very quickly appeared, and was even partially solarised.

2. A collodioned-plate was sensitised, exposed, and washed; then iodide of potassium poured over the whole of its surface: it was then washed, and again immersed in the silver bath. Under the action of the developer there appeared immediately a strong negative picture.

From the two experiments above mentioned we learn that iodide of potassium, employed before exposure, nearly destroys all sensitiveness to light, even when the — iodide of silver produced by it has been changed into + iodide of silver by again sensitising it after exposure, but that it is not capable of destroying the latent image after having excited the + iodide of silver by light.

I made a third interesting experiment in this direction, the result of which will surprise all those who have not yet undertaken it, namely:—In order to prove that iodide of potassium not only does *not* destroy the latent image, but actually preserves it against the further influence of light, a sensitised and exposed plate, which consequently contained the latent image, after being well washed, had a solution of iodide of potassium poured over it: it was then washed again, and exposed to the full action of daylight. Having then again been placed in the nitrate bath for a few moments,

the sulphate of iron developed a not very intense, but still a very perfect, clear negative, with no signs of fogging.

I leave it to every practical photographer to draw his own conclusions from these experiments, in order to turn them to the best account. *(To be continued.)*

ON THE PRESENT STATE OF OUR KNOWLEDGE REGARDING THE PHOTOGRAPHIC IMAGE.

Report of the Committee, consisting of Messrs. Maskelyne, Hadow, Hardwich, *and* Llewelyn.

(Concluded from page 268.)

A hiatus must needs occur in this stage of our inquiry. The sensitive film is exposed in the camera, and in a few instants the invisible image is impressed. We remove it, and our task begins again at a tangible starting-point. The development of the image is the visible evidence that the light has been at work, and a close examination of the nature of this image is the only further key we possess to elucidate the character of the light's action.

By a comparison of the developed images formed on plates that have been exposed for the correct time to produce a good picture, with such as are produced by the direct action of the light, we arrive at two conclusions. First, a general similarity in the appearance of the various sorts of images by each method is observable; but, secondly, the deposit in the case of the developed image is far more abundant than that in the direct image. The comparison as regards the quantity of deposit in any two images is one far too delicate to be effected by the balance; but a method of instituting such a comparison with great accuracy is founded upon the ready conversion of any such images into sulphide of silver, a body transparent and yellow in thin layers, but passing through tones of sepia to almost a black opacity as the thickness is increased. The colour becomes thus a good means of comparing any two deposits, and the complete conversion of these into the sulphide is ensured by the use successively of chlorine water and of sulphuretted hydrogen. A similar comparative result may be obtained by substituting the chloride of mercury for the chlorine water.

Now the deposited images in the case of the processes by development present some points of great analogy to those formed in the direct processes; in others these images widely diverge from them. Thus, we seldom find in them those purple and violet tones which seem to characterise the subchloride of silver before fixing. On the other hand, we observe two classes of developed images: the one is of a dull metallic appearance, of a slaty grey character by transmitted light, and in but a feeble degree opaque; the other varies in colour, exhibiting brown or red hues, and sometimes even presenting perfect opacity to transmitted light, closely similar to the picture formed by direct processes. But, on testing these two varieties of image by the method of conversion into sulphide of silver before described, it is found that the dull translucent metallic image teems with silver, and becomes very opaque in the form of sulphide, while the more richly-coloured and dense-seeming image loses opacity under the sulphurising action, and exhibits at last a subdued tone of colour that brings it more on a par with the sulphuretted metallic image. Clearly, then, here density, and the qualities which give photographic value to an image, do not depend on the amount of metal that goes to form it, so much as on the chemical, and even perhaps mechanical state, in which that silver is present in it.

The several causes which determine the deposit of the images in these several states appear to be these:—

1. *The materials forming the sensitive film.*—Pyroxyline, in chemical purity, has little tendency to form the darker image. Albumen and the heterogeneous substances (including decomposed collodions), which we have had to yoke in the same class with it, have this tendency.

In general (speaking of the ordinary moist process) the tendency to produce the darker image is found to be in something like an inverse ratio, *cæteris paribus*, with the sensitiveness.

The use of the bromide of silver with the iodide imparts to a collodion film a tendency to deposit the grey metallic image, at the same time that a more powerful reducing agent is needed to develop it. It is a remarkable fact, bearing upon this singular property of bromide, that no compounds analogous to that formed by A. Kremer with the iodide have yet been formed with it. In the case of albumen, this influence of bromide is not felt; for with albumen bromide of silver is held to increase the opacity of the image.

2. *The nature of the developing agent.*—The substances used to develop the latent image, besides the free nitrate of silver invariably necessary, embrace also without exception one ingredient, the character and the purpose of which is to reduce the salts of silver. In some cases organic bodies are employed for this purpose, in others the reducing agent is inorganic. Now, whether the grey or metallic form of image is completely reduced silver, and the more opaque forms are an argentous compound (mixed or not with metallic silver), or whether all the forms of image are silver in different mechanical states of deposition, is a very important inquiry, and one on which the facts of the development and the nature of the developing agent may throw some light.

But no one who is intimate with the complex and perplexing details of this step in the photographic process will expect the chemist to come in and remove the difficulty by the use of a few formulæ. All we can hope to do is to point to a few sure results of experience, and indicate any explanation which may be suggested by facts from the laboratory analogous to these.

It is known, then, that to produce a "positive" picture in the camera the developing agent should be sulphate of iron, acidified in some cases even by nitric acid. The result is the crystalline white deposit of metallic silver. Protonitrate of iron is used with a similar result. So likewise in the laboratory it is known that a neutral mixture of the ferrous sulphate and nitrate of silver forms the grey deposit, but that the addition of a little acid produces the white and brilliant form of the metal.

If now we would take a result opposite to this from the experience of the photographist, we may select an ordinary collodion plate prepared by the usual negative process, and we shall find that protacetate of iron develops the image of a black colour. Now Rose, in the remarkable experiments on the production of argentous compounds with the higher oxides of iron, &c., to which we have called attention, shows that whereas the argentic salts containing strong mineral acids are precipitated as grey metal by ferrous salts containing similar acids, the deposit formed by uniting the ferrous oxide and the argentic oxide, or the compounds of these with organic weak acids, contain the suboxide of silver and are black.

When to this is added the circumstance that the white and grey photographic images are with facility amalgamated with mercury, but that the coloured and black images are not, it may be treated as a matter of high probability that the black and coloured images are formed by compounds of the suboxide of silver.

A directive energy is exercised upon the nature of the deposit by the various kinds of organic matter employed in the development. These all seem to restrict the limits of variation to the dark bluish black (given by citric acid when present) on the one hand, and various reds and browns upon the other; while, again, the presence of the albuminous and other substances, so often before referred to, is, as was above remarked, a sure means of forming these darker and coloured images. Indeed, albumen will determine such images notwithstanding that even free nitric acid be present with it. If it be a suboxide that causes the dark precipitate, that suboxide must go down in combination, and so resist the action of the fixing solvents.

But, 3. The character of the light has also a remarkable influence in inducing a grey or a dark character on the developed image.

If the picture has been produced by an intense light, as by a lens of large aperture, or as in the case of an exterior as contrasted with an interior view of a building, or as on a dull, misty day in contrast with a bright and sunny one, it will be found that, *cæteris paribus*, the tendency of the weaker action of the light is to allow the reduction of the silver in the metallic form. On the other hand, the more intense light has given to the molecules of the sensitive film a controlling energy which they exercise on the deposit, and which appears analogous to that of the light in the direct process, in its modifying the reduction and giving it the form of a production of an argentous compound; as though the iodic compound became in a certain sense phosphorescent to the chemical rays of the light, and operated on the mixed silver salt and reducing agent as they float over it in the manner that the direct light might be supposed to do.

Of course the materials must be nicely balanced, as regards their tendencies to produce the black or the grey images, for the peculiar action of an intense or a weak light to be made fully evident. Albumen or powerful organic agents will usually destroy this balance.

One fact remains to be observed. Whatever may have been the character of the first particles deposited on the plate that character will be maintained thenceforward, and fresh deposits

may be, so to say, piled upon the first by the singular agglutinative tendency of crystalline deposits, so long as the necessary conditions of fresh silver solution and of fresh stores of the reducing agent be supplied to keep up the action.

Our task has been, by an investigation of the chemistry of the image in its different varieties, to afford some data, at least, by which the further step may be hereafter taken of determining the precise character of the photo-chemical agency, to whose marvellous influences art owes so many beautiful results, and science is indebted for more than one intricate problem.

GOVERNMENT IN COMPETITION WITH PROFESSIONAL PHOTOGRAPHERS.

No. II.

On the present occasion we place before our readers the evidence given before the Select Committee on the South Kensington Museum, by Henry Cole, Esq., C.B., Superintendent of the Museum, as far as it relates to the photographic department.

350. *Chairman.*] Will you describe the collections of photography and reproductions ?—The photographic department of the South Kensington Museum has arisen from a desire expressed by the various schools of art throughout the country to obtain specimens of the highest objects of art at the cheapest possible rate. During the Paris exhibition the Emperor of the French was good enough to allow the British authorities there to have practically almost unlimited access to the collections of the Louvre, the Musée d'Artillerie, and elsewhere; and hardly any restriction whatever was placed upon the reproduction of any objects in those museums. As respects photography, I will show the Committee some examples of the uses to which it is turned *(producing some coloured photographs).* The Committee is perhaps aware that the collection at the Louvre is the richest in the world in objects of the class of enamels and crystal, and of course it may be presumed to be not at all likely that they will ever go out of Paris. By the good nature of the Emperor of the French, we were allowed to photograph and colour those objects so that we are enabled to give our people the benefit of them at a comparatively insignificant rate. That is one illustration of photography. I have here another, which is a *facsimile* of one of Raffaelle's drawings. At a recent sale at Christie's a drawing not larger than that, and not finer in quality, sold for more than £200. A *facsimile* of this drawing, by the agency of photography, and by the action of the department, any working man in the country may get for 5d. I would apologise for the department being something that looks like a trader, but I am afraid that it is Hobson's choice; either the department must be a trader, or the public cannot have the copies. I know, as a fact, that the Emperor of the French has not even allowed his own subjects to have the privilege which we are giving to our school of art; and I believe that unless the instrumentality of the Government had been exercised the thing could not have been done.

351. That is with regard to foreign Governments ?—Yes.

352. With reference to copying things at home, why cannot we leave that to private trade ?—At the British Museum the trustees could not permit the public to take out objects whenever they pleased to photograph them; it must be done by some one person in whom the trustees have confidence; accordingly they appoint a photographer, and by harmonious action between us and the British Museum the same photographer acts for both. In our own department, it must be obvious that we could not give any body the run of the collections, or allow them to have objects out when they pleased, with the risk of breakage; we have to take extreme precautions now that the objects are photographed by our own photographer; but it would be practically impossible to place the collections in the hands of the public to do the work themselves. Passing on to another case, the University of Oxford did not hesitate at all to entrust its Raffaelle drawings to the department; I doubt very much whether they would have entrusted them to any other body but a Government department to photograph them. The same thing applies to Windsor Castle; the Queen has been so gracious as to allow us to photograph anything at Windsor Castle which the schools liked to make use of, and to allow the public to purchase them. Here is a photograph of one of the Holbein drawings *(producing it)*, the original of which would sell for a good many pounds; but this, according to the tariff of the department, can be obtained for 1s. 1½d.: this is no competition with trade, because private trade cannot do it.

353. You say that private trade cannot do these things; why not ?—Because nobody would give it permission.

354. Are there any regulations in the department which restrict its operation to things which would not be open to private trade ?—We scrupulously avoid photographing anything which the public can photograph for itself. For instance, we have had occasion to take photographs of trees for the use of our schools, and we have been applied to to sell them, but we have refused to do so upon that ground.

355. Upon the ground that you would not interfere with the private trader ?—Yes; and moreover, if the public desire to produce those things for themselves, there is nothing to prevent their coming and ordering from us what is called a "negative," and then they can print from it as many copies as they please.

356. Mr. *Kinnaird.*] For trade purposes ?—Yes.

357. Mr. *Joseph Locke.*] Cannot they do that without coming to you ?—They cannot go into Windsor Castle or into the Louvre to take the negative.

358. In places to which they have access they can do it precisely as you do ?—Yes; but there we do not act at all.

359. *Chairman.*] As to the cost of that department, is it self-supporting ?—I am in hopes that when it is in full action it will be. It has only been established during the last year, and at present, as in most cases of this kind, we have to get a little experience. We had not room enough at first, and we worked a little to waste; but even now it is very nearly paying its expenses, far more than the Ordnance Survey, which is a precisely analogous case.

360. Have you anything more to add upon that subject ?—I will hand in the rules upon which the public can obtain photographs. *(The same were handed in).*

Appendix (C), No. 10.

Official Photographs.—May, 1859. No. 341.

1. To enable the public to derive the fullest advantage from the negatives which have been, or may be hereafter, made, officially, for the department, from rare and valuable objects in foreign museums, and in other collections which cannot be photographed by private agency, the following tariff of price for "positive" impressions has been sanctioned by the Committee of Council on Education:—

For Unmounted Impressions.

	s.	d.
A single impression, the dimensions of which contain less than 40 square inches, *e.g.* 5 × 7 inches, or 4 × 8 inches	0	5
40 square inches, and under 60	0	7½
60 ,, ,, ,, 80	0	10
80 ,, ,, ,, 100	1	0½

And so on, adding 2½*d.* for every 20 square inches or under, up to 500 square inches. For prices above 500 square inches, *see* detailed list.

2. The department does not charge itself with the mounting of impressions, which the public is able to do for itself, but the agent will afford every information on the subject of mounting.

Photographs of Objects in the Museum of Art.

3. Artists, manufacturers, and the public generally, who may desire to have photographs of any special objects in the museum of ornamental art, can order negatives of such objects at the rate of 3*d.* per square inch. Any size under 30 square inches will be charged as 30 square inches. One proof of the negative is included in the charge for the negative. The department does not undertake to print any further impressions, but they may be ordered from Mr. Thurston Thompson, 1, Campden Hill Terrace, Kensington.

* * * * * * * * * * * * * *

370. Mr. *Adderley.*] Has there been much sale for those photographs in the office ?—There would have been a very large sale if we had been able to supply them; but our means of production at present are not at all equal to the demand; the public have a most hungry appetite for them.

371. Is the demand chiefly from schools or from the public ?—Both; schools have largely demanded them, and so have the public who have come to the museum.

372. Mr. *Joseph Locke.*] Does that answer apply to all the photographs ?—Yes; there is a run sometimes upon one more than upon another.

373. Mr. *Blackburn.*] For all practical purposes those photographic copies are as useful for educational ends as the originals ?—I should say, perhaps, that is a little stronger than the fact would justify; but where you cannot get the original, this is so clearly like the original that it nearly answers the purpose. Of course the thing itself has qualities about it which no copy in the flat can ever realise; you cannot get the translucency of the original, for instance.

374. For educational purposes, is not the copy as available as the original ?—A person who understands these matters will not be content with a photograph of the object if he can get the original; he would have a photograph rather than nothing.

375. Mr. *John Locke.*] You were speaking of the photographs that have been taken of works of art at Windsor Castle and at Oxford. By whom were those photographs of the Cartoons at Hampton Court taken ?—By the same photographer.

376. Were those taken for the South Kensington Museum ?—Yes.

377. Those are for sale at Colnaghis', are they not ?—We allowed Colnaghis to have the facilities of the apparatus and stages that we put up; we applied to the Office of Works for permission to photograph the Cartoons, and we gave an assurance that they should be watched during the process, and the sappers were responsible for lifting them up and down. We went to some expense for apparatus, and we did the whole business most carefully. We were asked if we had any objection to Colnaghis on their own responsibility doing the same, and we had none at all.

378. In fact, Colnaghis made those photographs upon their own account ?—Yes; if they could do it better than we, so much the better for the public; at all events we were willing that they should try.

379. Was there any offer made by any persons with respect to photographing the works of art at Oxford or Windsor ?—No; only with respect to the Cartoons.

380. Mr. *Stirling.*] With reference to these photographs which you have produced, are coloured photographs of this description sold at the establishment as well as plain photographs ?—They could be obtained, I think; there has been little demand for them. The coloured copies have been usually for the use of schools, and necessarily they cannot be made very cheap; a coloured copy like those which I have produced, and which I should say is the work of the students in the schools, would probably cost two guineas.

NOTES FROM THE NORTH.

By an Edinburgh Correspondent.

No. I.

Here, as elsewhere, clouds, rain, and wind form the staple of our weather, and, I fear, will tell upon our ensuing Photographic Exhibition. Let us hope for a change.

The various photographic clubs in this City are resuming their meetings, but it will be next month before the Photographic Society of Scotland again takes to business. There are rumours that a new Photographic Society is about to be organised in Edinburgh. Should this be the case I have no doubt that, if energetically conducted, it will prove a great success; for, from whatever cause it may arise, the above-named society is not so popular here as could be desired, especially among professional photographers. Indeed, considering the numerical strength of the profession in Edinburgh, it is perfectly marvellous that the only professed society here should contain so few of them. A large exodus, embracing the highest talent and skill, took place a few years ago; and the misunderstanding, if such it were, seems never to have been again adjusted: hence, if a new society be formed, the practical and professional element will doubtless be largely represented.

On the supposition that a new society is about to be formed, it may not be amiss to mention here an important addition, and one which would conduce exceedingly to its popularity, especially among amateurs. It is the addition of an operating-room, fitted up, not only with glass for *day* work, but with the most improved mode of artificial lighting for working after dark, when the ordinary avocations will have drawn to a close for the day. This naturally leads to a consideration of the various modes of producing artificial light of such actinic power as to enable a photograph to be taken from the living subject; for, with an ordinary gaslight, and the exposure of a minute or two, it is possible to reproduce an engraving or lithograph in the camera, but for a portrait from life something vastly superior is required. Among artificial lights, I take it the

"electric" ranks foremost. Rich in actinism, of great intensity, and capable of being increased *ad libitum*, this beautiful illuminating source stands, in my opinion, unrivalled. Compared with common carburetted hydrogen gas, the blue ray predominates to an extent that could scarcely be believed, unless by actual comparison. This looks pale and sickly, that glows like a miniature sun. Contrast can alone show the pure quality of the one over the other. It is a matter of dispute as to which battery produces this light most economically and simply. Could Smee's in moderate quantity do this it would, from its simplicity, be undoubtedly superior to any of the others; but, so far as I am aware, Grove's and its modifications are usually employed. My own experience has only been with Bunsen's, in which the platina of Grove's is economically substituted by carbon. Forty average-sized elements of this produces a very excellent light; and I have it on the authority of Mr. Hart of this place — who, perhaps, more than any one in Scotland, has had great experience in the construction and working of electric lights—that, with a proper "burner," twenty good elements of Bunsen's will produce a light equal to a moderate oxyhydrogen light.

The bother attendant on a battery of forty or fifty elements is such, that this source of illumination will, for the practice of photography, especially among amateurs, remain in abeyance for a considerable while longer — at least I rather suppose so. In every way more readily under management, and much more convenient in working, next comes the lime—magnesium or oxyhydrogen—light. By the way, I may state that I have never tried or seen magnesium substituted for lime, hence cannot say, from experience, what improvement is caused by the substitution. It is, however, said to be an improvement. Common gas, or carburetted hydrogen, seems to be a very excellent substitute for pure hydrogen in this light. The cheapness and universality of common gas seems to go a great way to recommend it. In any experiments which I have seen, the quality of the light did not seem much varied, whether the hydrogen were pure or carburetted.

There seems to be a certain amount of fear about using this light, which I cannot but consider as ill-grounded. All explosion may be avoided by a simple mechanical contrivance, viz., causing the gas to pass through either a tube stuffed with wires or a few layers of fine wire gauze. There is no doubt that oxygen does require care; for, when contaminated with a very small amount of hydrogen or olifiant gas, it is very explosive. At a late meeting of the Society of Arts in this place, Mr. Alexander Bryson accounted for an explosion of some severity which had taken place, by the fact of the hole in the retort by which the gas tube is screwed in having been that day re-screwed by a blacksmith, and the minute traces of the oil used to facilitate the screwing generating sufficient olifiant gas to cause an explosion of a somewhat violent character. This, I believe, is the only objection which can be urged against this light, which otherwise is very excellent, yielding a good light, easily increased by an addition to the number of jets, ready for use at all times, and which may be turned off when done with. The cost of this light is very moderate.

Next in the category comes Moule's patent photogen. With the exact constituents of this light I am not acquainted; but a very excellent compound for producing a most brilliant light is—

Nitre	6 parts.
Sulphur	2 "
Sulphuret of antimony	1 "

This, when intimately mixed and fired in a small vessel, such as a pill-box, gives a light by which the "human face divine" may be reproduced in twelve or thirteen seconds. The only objection to this (and one which can easily be got rid of) is the fumes which arise. Here, then, are three modes of illumination, any of which may answer for an operating-room of a photographic society.

Were it not that these notes are already too long, I would enter briefly on the subject of the curvature produced by compound lenses, with reference to some remarks by Mr. Dallmeyer, at the meeting of the London Society. This, however, in my next.

LUMEN.

Letters to a Photographic Friend.

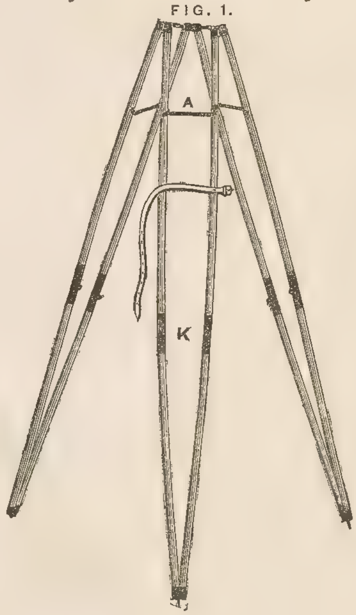
No. VII.

Dear Frank,

On returning to the attack at Messrs. Horne and Thornthwaite's, in Newgate Street, I found that they also had been giving their attention to the perfection of the bellows form of camera. Their arrangement consisted of a central frame permanently fixed to a portion of the base-board, to which the front part of the bellows body was attached, and into which it packed. The back frame that carried the focussing glass and plate-holder shut up close upon this central frame, and then the back and front portions of the base-board, being hinged, shut up on each side, just in the same way that the cover boards of a book close upon the letterpress portion. When packed in this the camera was between five and six inches in thickness. To bring it into action, the central portion is clamped on to the tripod stand, the front and back parts of the base board lowered, which are then made perfectly rigid by inserting two steel bars into deep grooves cut into each side edge, so that the three portions are clamped, as it were, into one rigid piece. The back frame with the bellows body is then drawn back and clamped to the hind portion of the base-board. A conical front, made of black cloth, is then drawn forth from the front of the central frame, attached to a piece of wood that carries the flange plate of the lens, and the latter is then secured to the front portion of the base-board by means that secure rigidity. Thus a camera intended for large plates packs into a small compass, and yet places a long range of focus at the disposal of the operator.

I have now to draw your attention to one of the most ingenious, and at the same time one of the most rigid tripod stands I have hitherto seen; but to render its construction clear I must call in the aid of my pencil. *Fig.* 1 shows the stand set up for use, and you

FIG. 1.



will see that the two limbs of each leg are kept *taut* by a forked hinged bar A. Now, the peculiarity of this stand is, that the legs are not separated from the tripod head when done with, but the whole stand is kept together; and yet, by the way in which it is made to fold up, it occupies no more space, if so much, as an ordinary set of legs, and is in every way more convenient. *Fig.* 2

FIG. 2.

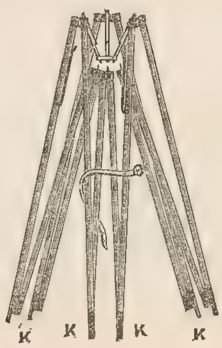


FIG. 3.

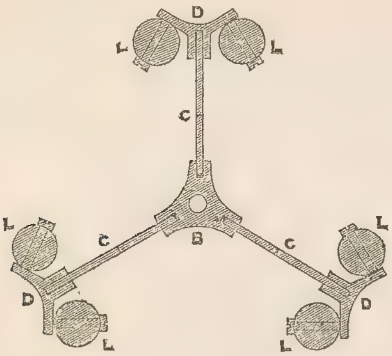
will give you an idea how this stand folds together, which you will better understand by consulting *fig.* 4, which shows how the

FIG. 4.



tripod head is made up of a central portion, B, to which three bars, C, are hinged, and to the other extremity of these other fittings, D, are hinged, to which the upper limbs of the legs, L, are attached by pivots. *Fig.* 5 will at once show you how the tripod head shuts up, in fact somewhat after the manner of the ribs of an umbrella, the reference letters corresponding with the parts in the preceding figure. The next point to make clear is the construction of the knee-joint, K, shown in *fig.* 6. L is the upper limb, and *l* the lower limb of one of the legs; the lower end of L is shod with a piece of tube, cut so that a portion is bent out to form part of a hinge, whilst half of the tube beneath it, M, is cut entirely away. The upper end of *l* is also capped with a piece of tube, likewise having a portion split and turned outwards, so as to form a hinge when connected with the other piece by a wire passing through from one side to the other. The sides of the tube at M are slightly bent inwards, so that when the limb *l* is brought into a straight line with L, it acts as a spring on the upper part of *l*, and keeps it rigid. If the two surfaces of the mahogany limbs were allowed to come in contact, a tremulous motion would at times be imparted, so the limb L is only allowed to pass into its tube as far as N. *Fig.* 3 shows the stand packed—and it certainly is the most compact, light, and efficient set of legs I know of. As the newspaper reporters say, in speaking of some benevolent person or "jolly good fellow," it "has only to be known to be esteemed." Without doubt it is a capital dodge. When set up, as in fig. 1, the little pieces that you see projecting from the ends of the bars C C in *fig.* 5, act as stops or bearings when the camera is screwed on to the tripod head, and rigidity of course is not secured till the camera is screwed in position.

FIG. 5.

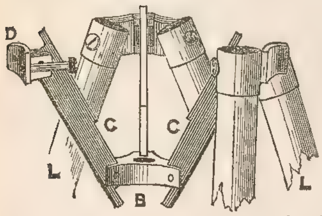


FIG. 6.

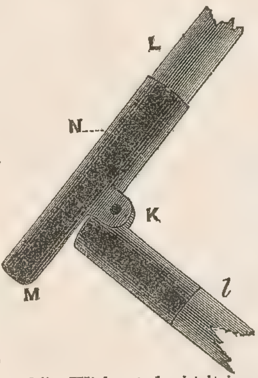

I next made my way to the London Stereoscopic Company, in Cheapside, and examined an extensive series of photographs of American scenery lately introduced into this country. These comprise not merely stereoscopic subjects, but large views of the most interesting spots in Canada and the United States. Of course Niagara figures largely in the series; and one is easily able to form a very good idea of the grandeur of those mighty Falls by examining such stereographs as *The Rapids*, No. 115; *The General View of the Falls from Prospect Point*, No. 140; *The Horse-Shoe Fall and the Terrapin Tower* (instantaneous) No. 153; and the *Table Rock*, from the base of the Horse-shoe Fall. Among the large photographs there is a capital panoramic view of the entire scene. Most persons in England have been in doubt as to whether Blondin was not an apocryphal personage, but a stereograph in this series depicts a gentleman in the usual "India-rubber—incredible-brother" costume, poised on a rope over the rushing waters of Niagara. This is something like an authentic proof that Blondin had an existence otherwise than in the fertile brains of a Yankee editors or in the veracious and voracious columns of American newspapers. Slide 136 gives an exquisite rendering of the stalactite-like icicles in one of the ice caverns of the White Mountains, New Hampshire; *The Chaudier Falls*, No. 113; *The Cataracts on the Genesee, near Portage*, No. 125; whilst many other of these stereographs present objects of great interest. Moreover they are as well executed as the points of view are well selected.

From "Under Bow Bells" I went away to Mr. Squire's, of King William Street, to inspect Leake's Dark Tent. This, for stereoscopic work, consists of a tray 22 inches by 12, and 2 inches deep; into this packs a kind of black bag, made impervious to light, the lower margin of which is tacked to the inside of the tray, and the upper margin to a piece of wood that forms a lid to the tray; after the tray is attached to its tripod stand, the bag or tent is pulled upwards, and then kept perfectly rigid by means of two stout brass rods (one on each side) being forced into indentations made in the tray and lid to receive the ends. The dark chamber is then about 22 inches high, with a yellow window in front, and an aperture behind to receive the upper part of the body, light being excluded by a curtain falling over the back of the operator. This tent is very rapidly put up or struck, is exceedingly portable when shut up, and is the lightest I have yet seen.

Having got to the photographic end of the City, I have got to the end of this letter. In my next I purpose recording the results of my wanderings in many an unknown nook of London. But if you should not hear from me again, apply to the Dead-Letter Office or the Found Dead Department of Bow Street; for I have a vague idea that I am going to spots where rampant cattle do congregate and pitfalls abound, through the projectors of new streets keeping open house—as far as their cellars are concerned.

So believe me,

Yours, bound for the back settlements,

SIMEON HEADSMAN.

STEREOGRAPHS.

Instantaneous Marine and Street Views, by GEORGE WILSON, *Aberdeen.*

PERHAPS one of the most striking and really valuable steps in advance that have been made during the past twelve months in the practice of photography is that of the excellence to which the production of "instantaneous" photographs has been brought in the hands of some of our more highly-skilled operators. One of the first of this class of subjects, which took the fancy of the photographic world by storm, was the well-known *Brig*, by Le Gray; but this, beautiful and artistic as it undoubtedly was, possessed those merits in spite of its defects. The reality was a glorious blaze of sunshine flashing from out the rolling masses of clouds, and flooding the rippling waters of the ocean, which even in their quietude may be with truth described as ever restless: the semblance was of that same ocean partly veiled by night's soft mantle, and which the tender moonbeams touched with liquid silver. It was not exactly the truth, though perhaps as beautiful as if it had been.

In stereography we have, upon several occasions, had to draw attention to some well-designed attempts "to fix the fleeting shadows as they passed," and these have generally been nearer to the truth, though perhaps not more artistic than Le Gray's *Brig*. If the whole truth must be told, also, we have still more frequently had to be silent and make no sign when specimens of "instantaneous" views have been received for criticism, for there is no need to tell the world when such an one has failed in a well-meant aim; and we only allude to the subject at present in order to point out the fact that now many of the earlier difficulties have been overcome. We no longer get mere black and white in these productions, but a considerable share of half-tone. Moreover, we now have not only marine subjects, but busy street scenes, with all the active bustle of daily life portrayed therein. It might be thought by the novice that if it be possible to catch the form of the breaking wave, it is no great feat to obtain also the view of the crowded thoroughfare; but this is quite a mistake. There is something in the atmosphere at the seaside which gives the operator in that kind of

locality a decided advantage over his more inland situated brethren, especially in the point of time of exposure. In the slides by Mr. Wilson, now before us, however, we have to deal with both the kinds of localities mentioned.—And first we have three of

PRINCES STREET, EDINBURGH, *looking towards the* CALTON HILL.—These are all excellent as photographs, being quite free from anything approaching to under-exposure, and are full of half-tone. Numerous vehicles and pedestrians are to be seen, some in rapid motion. Though all three slides are good, No. 190 is, in our opinion, decidedly the best. It not only contains the greatest number of figures, but they are also well-defined and sharp, even those nearest to the camera. This slide, as regards manipulation, is decidedly superior to the views in Broadway, New York, that we noticed some short time back. The very gait and aspect of the passers-by would, of necessity, be recognised by their acquaintances.—As companions to the preceding, we have two of

THE QUADRANT, and one of the upper part of REGENT STREET, LONDON.—In No. 206 there are several Hansom cabs advancing at a rapid pace towards the spectators that are exceedingly characteristic of the style of progress peculiar to that kind of vehicle, and which are capitally defined; but, strange to say, a foot passenger running after an omnibus, whose figure occupies one corner of the picture, is sufficiently blurred to show that, quick as the exposure must have been, yet still it occupied an appreciable space of time. It also demonstrates the optical difficulty in correcting the oblique pencil of rays.—No. 205, representing the upper part of the street, with a goodly array of pedestrians on *the fashionable side*, albeit not at the fashionable hour, is a very attractive subject, and will no doubt be in great demand.

We now turn to the marine subjects. And here we would remark that, with one or two exceptions out of about twenty before us, there is nothing of the *moonlight* effect to which we referred in connexion with Le Gray's picture; but neither is there in most of them sunshine displayed—most probably for the reason that, when the negatives were taken, no sunshine was visible

"O'er the glad waters of the dark blue sea."

There are some half dozen views taken FROM RYDE PIER, ISLE OF WIGHT, in which various pleasure yachts may be seen, bending to the breeze. As Byron says,

"How gloriously her gallant course she goes!
Her white wings flying—never from her foes;
She walks the waters like a thing of life,
And seems to dare the elements to strife."

These slides are admirable, portraying all the varied beauties of clouds and waves, and are to the marine artist invaluable.—Nos. 243 and 244 are particularly pleasing: in the latter the cloud of steam issuing from the funnel of a steam-packet in the distance is very effective.

THE STRANDED COLLIER (No. 238) is a perfect marine picture—stranded on the soft wet sand, and heeled over a little on the larboard side, with sails all furled and trim. Two carts are alongside, to ease her of a portion of her burden of black diamonds. One of the carts is "backed" close to the vessel's gangway, and is in the act of receiving a load—the horse in the attitude that reminds one so strongly of the soldier at the word "attention!" Some of the crew are visible on the deck; and the broken reflection of the whole is seen in the sloppy sand of the foreground, while a low sandbank is seen behind, and beyond that a brigantine at anchor. This slide will certainly be highly popular.—There are half-a-dozen slides of

THE GREAT EASTERN IN THE SOUTHAMPTON WATER, which, irrespective of the interest attached to the vessel itself, are beautiful as studies of clouds and waves. Where all are so good it is difficult to make a selection; but we cannot forbear particularising Nos. 219 and 220, in which the breaking wave on the shore is rendered with peculiarly happy effect.—No. 223 is one that presents a little of the moonlight effect, but is especially beautiful from the fleecy clouds that are portrayed. The waves are here much smaller than in the other pictures, and that on the sand displays the white foam to advantage.

With some seven or eight illustrations of the FRITH OF FORTH we shall close the present notice. There are two of the CHANNEL FLEET, in which the frigates are to be seen decked in gala attire of countless flags; while steamers and sailing vessels are scudding about in various directions, like dogs gambolling about the footsteps of their masters.—The remainder are representations of

H.M. SHIP "EDGAR" and H.M. SHIP "ROYAL ALBERT," under various aspects. These are at anchor, and the numerous portholes for their many tiers of guns can be counted with precision.—

"Far on the horizon's verge appears a speck,
A spot!—a mast!—a sail!—an armed deck!"

Nos. 224A and 224B are truly exquisite productions. In the former numerous yachts, with their snow-white sails, are coursing around the vessel of war like lambs round a fortress. In the latter a steamer, towing a line of sailing barges or some such craft, deeply laden, is crossing in front of the frigate, and the long trail of white steam testifies to the speed of her progress.—No. 225 is also an admirable study of shipping.

We cannot conclude without congratulating the art-loving portion of our readers on the rich treat in store for them in studying these admirable productions.

Bath and its Environs, by H. N. KING.

THE ancient city of Bath, the existence of which dates back as far as the time of the Roman occupation of this island, and is celebrated for its natural hot springs, has found an able illustrator, photographically, in Mr. King, a resident in that attractive spot. Who has not heard of its once famous Assembly-rooms—immortalised also in "Pickwick?" Who has ever passed it when progressing along the Great Western Railway without feeling a desire to stay there, if only for a day or two? And if such desire be the effect of a passing glimpse of that renowned city, an inspection of the stereographs now before us is not at all likely to lessen it. We have neither time or space to notice the whole of them, but must devote a few lines to some that strike us more prominently than the remainder. And, firstly, we must call attention to WIDCOMBE OLD CHURCH AND MANOR HOUSE, No. 2, both being quaint and ancient structures, picturesquely situated—the former having a square tower literally enveloped in ivy, and pierced by several gothic windows. On one of the pinnacles is seen the symbol of the "cock," the emblem of St. Peter's weakness, and the origin of the "weather-cock," now but rarely seen in the form which makes the appellation an appropriate one. This is an exceedingly pleasing slide, as is also another which gives a different view of the church, disclosing somewhat more of the basement portion.

THE MANSION IN PRIOR PARK, No. 20, is an excellent specimen of the architectural series, and gives a good idea of the edifice which it is intended to illustrate.

PRIOR BIRD'S PRIORY, No. 17, is one of those quaint, snug, old-fashioned domiciles with red-tiled roof and pointed windows in which some of the church dignitaries of old made themselves very comfortable. It makes a capital picture, with its broken outline and numerous creepers lovingly entwined about the various casements; while, as a background, a group of trees, in which the elm, fir, and yew are readily recognisable, acts as a foil to throw up the building prominently; and the thin wreath of smoke from one of the chimneys gives evidence of human habitation. The garden is on a slope; and in the centre of a lawn in the immediate foreground is an extensive circular pond, with a fountain in full play, which only ripples the water sufficiently to veil the sharpness of outline of the soft, reflected image of the house. This will certainly be a favourite with purchasers.

THE PALLADIAN BRIDGE, PRIOR PARK, No. 29.—Of this subject there are two illustrations from different points of view; but that numbered as above indicated is far the best, and is in every way an excellent photograph.

VIEW AT THE PARK POND, VICTORIA PARK, BATH, is a good illustration of variety of foliage, and the aspect presented by different kinds of trees picturesquely grouped.

The difficulty of properly rendering foliage together with other objects, each with its due amount of relative light and shade, is acknowledged by every practised photographer, and it is a problem the solution of which deserves the best energies of all scientific operators. The details of Mr. Heisch's labours towards this end should be carefully examined by all who work in this direction.

BATH, FROM BEECHEN CLIFF.—Under this title there are four different views, comprising an extensive range of the chief parts of the city: these must be regarded as fairly successful, for we are informed that it is but rarely that a *clear* view of Bath can be obtained from the spot, which is between two and three miles distant, but when clear the view is a particularly pleasing one.

We are informed by Mr. King that he develops solely with iron, using no after intensifying process, and simply washes off the developer without fixing the negative until he reaches home, when he can fix properly, and afford the requisite amount of washing without stint of water.

Meetings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The Annual Meeting of this Society was held on Wednesday, the 3rd instant, at the Rooms of the Literary and Philosophical Society, George Street, Manchester,—Joseph Sidebotham, Esq., one of the Vice-Presidents, being in the chair.

Seven new members were elected.

The President said he was sorry to have to name that Mr. Edward Mann, the Honorary Secretary, had stated that he was unable, from his various other engagements, to continue the duties of Secretary. He (the Chairman) had once been the Secretary, and he knew that there was more work to be done than perhaps many were aware of. Mr. Mann had ably fulfilled the office for upwards of two years, and had at all times given the greatest attention to the interests of the Society. He (the Chairman) should be sorry to lose Mr. Mann as Secretary, and no doubt the whole of the members would join him in his regrets. However, there was another gentleman who was, he believed, willing to accept the office of Secretary, and who was well known to every member as having the interests of the Society at heart. He thought he need only name Mr. W. T. Mabley, as the gentleman to whom he referred, to ensure his unanimous election.

A vote of thanks was passed by acclamation to Mr. Mann for his past services as Secretary.

Mr. W. T. Mabley was then elected Honorary Secretary, and Mr. Edwin Offer, Treasurer.

The following gentlemen were elected on the Council for the present year:—

President.
The Lord Bishop of Manchester.

Vice-Presidents.
J. B. Dancer, Esq., F.R.A.S.
J. P. Joule, Esq., LL.D., F.R.S.
Arthur Neild, Esq.
H. E. Roscoe, Esq., B.A.

,, William Hooper,	,, H. Young,
,, Edward Mann,	,, G. Wardley.

Honorary Secretary.
Mr. W. T. Mabley.

Treasurer.
Mr. Edwin Offer.

After the election of the Council as above, Mr. Mann, the Honorary Secretary, read the following report of the Council for the past year:—

ANNUAL REPORT.

The Council of the Manchester Photographic Society, in presenting their Annual Report for the past year, have great pleasure in congratulating the members upon the very flourishing state of the Society.

The Treasurer's account shows a balance in hand of £50 17s. 3d.

There has been a considerable accession of members during the session, and the subscription having been now reduced (in consequence of the decrease in the expenditure) to 10s. 6d., with fee of 10s. 6d. for entrance, it is anticipated there will be a much larger increase during the next year.

The meetings have been generally well attended, and the experiment which has been tried of continuing the meetings throughout the year, instead of having a vacation as before, has been attended with complete success, and many very interesting meetings during the summer have been the result. Notwithstanding the extremely unfavourable photographic season, most of the members of the Society have made considerable and valuable additions to their stocks of negatives, and numerous excellent specimens have been presented by them to the Society's portfolio, which has now become a very bulky and interesting record of the progress of the art.

The Photographic Exchange Club has, so far, progressed very favourably; and it is anticipated that the contributions will be ready for distribution among the members on or soon after this evening.

The following papers and subjects, among many others, have been read and brought before the meetings during the year:—

Mr. W. T. Mabley read a paper, written by George Shadbolt, Esq., expressly for this Society, *On the Focus of Lenses.*

Mr. Dancer contributed an Oxyhydrogen Lantern, with the requisite apparatus, and exhibited numerous very beautiful transparencies upon the screen, they being entirely the productions of the members of this Society.

Mr. W. T. Mabley read a very interesting paper on the subject of *Photographic Printing on Paper*, which was illustrated by numerous specimens.

Dr. H. E. Roscoe read a paper, entitled, *Some Points concerning the Measurement of the Chemical Action of Light*, and which he illustrated by various diagrams and interesting experiments.

Mr. Mann, the Honorary Secretary of the Society, read a paper on some experiments made by Mr. H. Petschler and himself, communicating some new and important chemical facts with respect to the iodide and chloride of silver, and upon which Mr. H. Petschler had founded a very valuable modification of the collodio-albumen process. This discovery has attracted a good deal of notice, and is perhaps one of the most important matters brought before the Society during the session. As some misapprehension has arisen in reference to the originality of this process, it has been thought desirable to explain, in this report, that which constitutes Mr. H. Petschler's discovery. It had been previously discovered that the *application* of a chloride to an excited plate did not destroy its sensitiveness, and in all cases the chloride was removed by washing; but this operation was not adopted for the purpose of restoring a dormant sensitiveness to the action of light, but simply to prevent a crystallisation upon the surface. It was not known, so far as published accounts show, that the plate was rendered sensitive by the washing. The discovery, therefore, is, that a film of iodide of silver is insensitive when in presence of a certain amount of an alkaline chloride, or iodide, but after a dormant manner only, and that it may be excited simply by washing. Since the last report many members have experimented largely in several of the dry processes, but the opinion is general that there is not one which can surpass or successfully compete with the Taupenot. The process (above alluded to) of Messrs. Petschler and Mann affords much promise, but it is thought desirable that more experience should be gained of its capabilities before an opinion of its practical value is given. The subject of the dry processes, however, cannot be dismissed without mention of Dr. Hill Norris's latest improvement. Negatives have been shown in this room which were taken by an exposure fully as short as that required for wet collodion; and, although the results, so far as they have been made known to us, are wanting in tone and vigour, the step is so important and so suggestive of that which is most wanted, that it may be considered as the greatest event of the season.

Though the Society had very short notice of the kind offer made by the committee of the Salford Royal Museum and Library, to set apart a room expressly for the purpose of a Photographic Exhibition, a special committee was at once appointed, and a very excellent exhibition of the works of local photographers (with very few exceptions members of this Society) has been the result.

At the last meeting Mr. J. Parry read a paper on some very interesting and valuable experiments which he had made respecting the aceto-nitrate bath, as used for the collodio-albumen process.

The alkaline gold toning process has now come into universal favour, and it is a matter for great congratulation to notice the very superior and beautiful results produced by this the more correct method than the old ones, and which has the probabilities of permanency as well as superior whiteness and beauty of tone to recommend it.

The Council have great pleasure in calling the attention of the members to the fact that the British Association for the Advancement of Science have arranged to hold their meeting in Manchester during the next year, when it is hoped that some effort will be made by this Society to worthily represent the photographic art on that occasion.

In concluding this Report the Council have great pleasure in tendering their best thanks, on behalf of the Society, to George Shadbolt, Esq., the editor of The British Journal of Photography, the special organ of the Society, for the valuable assistance he has at all times rendered, and for the constant attention which he has always given to the general interests of the Society.

The Secretary then read the Treasurer's accounts, when they and the report were unanimously approved of and adopted by the meeting.

Mr. Wardley presented a series of photographic pictures, taken by the collodio-albumen process, of views in the Lake district, to the portfolio of the Society. These pictures were very much admired for their artistic effect.

The President called upon Mr. Parry, who had a communication to make to the meeting.

Mr. J. Parry then read a paper *On a Modification of the Collodio-Albumen Process.* [See page 298.]

A very animated general discussion took place on the subject of Mr. Parry's communication, particularly as to the extent to which the albumen would be coagulated by the hot water.

Mr. Dorrington said he had tried the method adopted by Mr. Parry, and had succeeded excellently with it, and he considered it a very valuable modification of the dry processes.

A vote of thanks was unanimously passed to Mr. J. Parry for his paper; and after a very interesting and numerously attended meeting, the proceedings closed with a vote of thanks to the President for his services in the chair.

On the table were a number of beautifully-executed photographs by the members of the Society.

CITY OF GLASGOW AND WEST OF SCOTLAND PHOTOGRAPHIC SOCIETY.

The first ordinary monthly meeting, for the season, of this Society was held in the Religious Institution Rooms, on Thursday evening, the 4th inst.,—J. Kibble, Esq., the President of the Society, in the chair.

A paper *On Printing and Toning on Albumenised Paper* was read by Mr. J. Stuart.

A lively and interesting conversational discussion followed the reading of the paper, in which the Chairman, Messrs. James Cramb, Hugh M'Farlane, J. Ewing, A. M'Tear, D. Brown, and John Cramb, took part.

The same subject was continued for next meeting, members being expected to come prepared with the results of their experience, whether successes or failures, in printing.

It was suggested that those who make albumenised paper for sale should tell the amount of salt employed by them.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER VIII. *(Continued.)*

SCUMBLING.

This is a process of glazing with thin opaque colour, and is very useful indeed to modify, subdue, soften, or alter the tone, texture, or crudeness of your painting. It is generally made use of in the second, as glazings are in the third, on finishing painting. In your background scumbling will aid you in securing the effect of atmosphere, and in all parts of the painting you will soon learn its value.

In adopting it, use the colour with a full brush, and without too much vehicle. Hard outlines may be got rid of by its use, and it serves more effectually than glazings do to destroy that painty appearance which I have before advised you to avoid. Scumbling may be adopted to alter the ground, when necessary, for the reception of fresh glazes; in which case the opaqueness is increased by the addition of white. Crude, raw colours may also be subdued by this process. Upon glazing and scumbling nearly all the richness, brilliancy, and transparency will be found dependent. Scumbling should be avoided, if possible, in the shadows. In dark photographs, however, it is necessary, although great care is requisite when using it in such parts.

IMPASTING.

Impasting, in the hands of the inexperienced photographic artist, requires such extreme care, and is so likely to destroy the likeness, if he has not that knowledge of drawing which would enable him to preserve it, that, by such, it should be but partially adopted; and then its effect should be obtained by continual applications, with intervals for drying after each, rather than by laying the colours on thickly at once (see maxims 40 and 53). Impasting is too valuable to be altogether dispensed with: by its aid we get more freshness, clearness, and brilliancy; and, moreover, solid colour is essential for preserving the beauty of the original painting, and aids also, by contrast, the effect of our transparent colours in the shadows — its use being chiefly confined to the lights. So effectual in securing brilliant high lights has this method proved, that many are tempted to carry it beyond reasonable limits, and lay the colour on so thickly as to produce an actual protuberance, which, casting its own shadow, produces a false effect, and conveys a more prominent idea of a lump of paint than of anything else (see maxims 7 and 39). In large heads impasting is as frequently done with the palette knife as the brush—the blade being of assistance in securing a flat surface to the pigment.

HANDLING.

To a certain extent handling may be regarded as a mechanical quality; but its power of securing texture gives it also a much higher attribute, every variety of surface having its expression secured by certain peculiar and characteristic methods of touch. A good style of handling cannot be obtained from any source but that of experience and practice; it may, therefore, be enough to advise that in the first colouring a bold, dexterous way of laying on the tints, clean and distinct, and placing each in its position with as little labour as possible,* can be used; that a more careful and laborious style of pencilling should follow; and that a small pencil, with thorough attention, patience, and thoughtfulness, be adopted for the finishing.†

You have to be cautious that your mode of handling does not degenerate into the mannerism of being the same for all surfaces, giving but one texture for the ruggedness of granite and the polish of marble, as is lamentably common with the vulgar "tea-boardy" productions exhibited at some of our "finish" (?) loving photographers' establishments (see maxim 6). Hatching and stippling are useful in the last painting; but these terms I have fully explained in the chapters devoted to water colours.

BLOOMING.

A technical term to describe the effect produced by applying a soft varnish when the surface of the picture is not thoroughly dry; or the operation is performed in cold damp air. It is sometimes called chilling, which is the more expressive word perhaps. To remedy such a defect, rub it off as soon as it appears with a piece of old silk and a little poppy oil.

OILING OUT.

As there is very great danger in varnishing a picture too early, a little drying oil is sometimes used, instead of varnish, to bring out the colours. This practice is known under the above term.

VEHICLE.

It may be as well to say that this term simply implies that which is used to make the colours flow from the brush, namely, oils, magilps, varnishes, &c.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. WALL, Esq., 11, THE TERRACE, WALWORTH.

MISS D. (Kingsland).—Your progress flatters me vastly. The various theories of symbolic colours are so purely speculative as to be almost unintelligible. In early art some such systems may have been pretty generally recognised; but we moderns have not much sympathy with those who attempt their revival. It is really little better than laborious idleness to enter upon the study, although there are many who, like yourself, feel deeply interested in it. I cannot just now recal the names of any writers who have devoted their labour to this subject; but there are many. It seems to me that colours derive their symbolic value from the mere association of ideas, which are themselves of a most chamelion-like character. Chevreul will give you something tangible and understandable—something practically useful. The quotation is from a work by Moses Harris, called "The Natural System of Colours." The other work you name was translated from the German of Libertat Hundertpfund — am sorry to trouble you to pronounce his name—and was published by Bogue, of Fleet Street. I am glad you are so earnest in your studies; but think symbolic colours might be safely let alone for more profitable labour.

ANNIE.—The outlines are too hard, the flesh-colours a little too raw, and the greys not clean enough: stop at the tinting till you have mastered it, then try to finish highly. The glass picture is all that could be desired.

JAMES.—A private reply was sent to the address given.

A SCHOOL OF DESIGN STUDENT.—Yes. Too late for the last number.

Foreign Correspondence.

Paris, October 10, 1860.

YESTERDAY I received a visit from an amateur whose conversation greatly interested me. My visitor was Dr. Sabatier, one of those modest *savants* who withdraw from men and from mundane noise to give themselves up to untiring work. He lives in a little village in the environs of Paris, where, amidst the calm of country life, he pursues his favourite investigations in entomology. It was his desire for completing the notes and descriptions resulting from his studies that led him to recognise the necessity of employing photography, and so he became an operator. Though the means at his command were deficient, and his instruction in the art elementary, he has yet succeeded, not only in acquiring a most curious collection in a scientific point of view, but also in elaborating a special process based upon a new principle, which may perhaps be a point of departure towards unlooked-for improvements in photography. I will communicate to you the description which Dr. Sabatier gave me of his method.

This process has for basis a capital fact which has hitherto remained unnoticed, namely, that certain substances, when poured in solution upon a negative *cliché which is in formation*, exerts thereon, whatever may be the developing agent made use of, such a *disturbing* and *substitutive* action that the development of the negative is arrested at the very instant of contact, and the chemical combination which follows the contact gives birth to a positive.

The substances possessing this disturbing and substitutive power are probably numerous. They include perhaps many of the neutral salts and all the alkalies; but from the necessity of limiting his investigations, Dr. Sabatier confined himself to nitrate of silver, ammonia, and lime-water, which all three possess the power in the highest degree.

To prove the reality of a fact of so great importance, and to put it beyond doubt, the following is his mode of proceeding:—

Upon a square piece of white paper he draws ink lines — broad and very black — and focuses so as to take a print of the paper on a glass collodionised, iodised, and sensitised as usual. After exposing the plate in the camera, he pours over it a solution of acidulated pyrogallic acid; then, when the whites of the paper begin to appear, and long before the action of the developing agent is exhausted, he washes the glass with distilled water, and covers it with a weak solution of nitrate of silver.

One or two minutes after this last operation, the whites do not appear to have changed, but the intensity of the blacks is inversely proportional to the length of time the pyrogallic acid has remained on the glass. The same result is arrived at if, instead of nitrate of silver, we pour over the glass a sheet of ammonia or of very weak lime water.

This experiment succeeds regularly and infallibly, provided the sensitising bath and the feeble solution of nitrate be perfectly neutral. It succeeds also if we take as developing agent gallic acid or protosulphate of iron that does not contain any sulphuric acid in a liberated state. This places beyond a doubt the disturbing and substitutive influence of the three substances experimented on, whatever may be the developing agent employed.

Dr. Sabatier establishes the reality of this influence without being able to explain it; but, for those who may attempt to give an explanation, and especially for those who cultivate photography, he calls attention to the following facts, the first two of which are, so to speak, but the corollaries of the capital fact established:—

1st. On the object-plate of his microscope, which he has blackened irregularly, he places a glass bearing a fly, and on the mirror situated immediately under the object-plate he puts a white paper, and then he takes the latent photographic picture of the fly. By proceeding in the operating-room in the manner described

---

* The beauty of your tints will be considerably impaired if "teased," or, in other words, too much worked about with the brush.

† I always like to finish my picture when the sitter is before me: my pupils should adopt the same plan, as it is invaluable to beginners.

below he obtains, not only a positive of the fly, but also that of the irregularly-blackened object-plate. But if for the white paper that forms the ground of the little picture we substitute black paper, although the exposure be prolonged and the light be more intense, we obtain by the same process in the operating-room neither the positive of the fly or that of the object-plate.

Let it not be supposed that the substitution of a black ground for a white one has intercepted all light; for the fly and the object-plate were very well seen on the ground glass. On returning to the operating-room the collodionised glass remains white in spite of its undergoing operations suitable for developing a positive, whereas it becomes black when it has not received the luminous impression. If the positive has not been formed, it is because it could only be the consequence of a negative which itself could not be formed.

2nd. As soon as the negative is entirely developed the positive is no longer possible, the nitrate of silver, the ammonia and the lime-water have no influence upon the negative arrived at the perfect state.

3rd. The positive is not developed at first in the whole thickness of the collodionised layer: it commences at the surface in contact with the glass; for it is seen on the side on which the glass is, while it cannot yet be perceived on the opposite side, and the hyposulphite, by dissolving the iodide not acted on, renders it visible on both sides.

From what precedes, it results then that nitrate of silver can, with each of the developing agents, determine two successive combinations of different colours — the one tending to the whites of the pictures and producing a negative, the other tending to the blacks and producing a positive; that these two combinations depend one on the other to such an extent that the second commences very exactly at the moment in which the first is arrested; that the second takes possession of the whole space that the first leaves to it; and that lastly, the second becomes impossible as soon as the first is completed. The more white we develop the less black we shall have, and *vice versâ*. The important — the difficult thing is to appreciate the proportion in which the two colours must be employed, to seize the precise moment of arresting the formation of the negative, so that the light and the shade may blend the most harmoniously: certain details even will not be well rendered unless we let one of the colours predominate at the expense of the other. The new method will demand not only the experience and the dexterity of a clever operator, but also the knowledge and the taste of a true artist. Each object to be represented will require a special study.

As will naturally be supposed, the new process will in no respect modify the operations that precede the use of the developing agent; it merely requires the arresting of the positive at a moment determined according to the effect that is desired. For that purpose we wash away the developing solution with abundance of distilled water, and cover the glass with a light layer of nitrate of silver at 4 per cent. All this must be done very rapidly, because in consequence of the pyrogallic acid still adhering, the negative continues its development even under the flood of distilled water.

It has been seen that the mere contact of the nitrate sufficed for determining the formation of the positive. However, if care was not taken to pour upon the damp plate a small quantity of pyrogallic acid, the positive, for want of material, would come with difficulty, and would be well indicated only in the very dark parts. When the nitrate stays one or two minutes on the glass without this addition, the positive is produced instantaneously, and the whites lose their brilliancy; but, if the nitrate does but pass, as it were, to give place immediately to the acid, the positive is developed before your eyes, and with the greatest precision.

If ammonia or very feeble lime-water were employed instead of the nitrate, care must be taken to wash the glass with distilled water, after the contact of those two substances, and then to cover it with pyrogallic acid, to which has been added a few drops of nitrate of silver. But what especially must not be lost sight of is, that success is impossible when the baths contain the slightest trace of nitric or sulphuric acid. Preference will, therefore, be given to fused nitrate of silver, and, for bringing out the picture, to pyrogallic acid, which here again maintains its unquestionable superiority.

Direct positives obtained by this process are fixed, as are ordinary positives, with hyposulphite, and take, as do those, the tone we desire to give.

Although collodionised glass alone has been here spoken of, the process is equally applicable to albumenised glass. It would even be applicable to paper, if anyone succeeded in giving to paper some of the qualities peculiar to the substances which are poured upon glass; and that seems the more possible, as paper is the basis of collodion.

Dr. Sabatier gave me, with this communication, twelve pictures. They are of great delicacy, and, when seen with the glass, they show the smallest anatomical details of the insects portrayed: the delicate network of the wings of a fly is distinctly perceived in these transparent designs, and one might count the brilliant spots in the elegantly water-marked coats of certain other insects. What marvellous results Dr. Sabatier might obtain with Bertsch's photo-micrographic apparatus, which would give him a magnifying power of three or four hundred diameters! His collection, already so interesting, would become a real monument of science.

ERNEST LACAN.

☞ The Publisher, in reply to continual inquiries, begs to inform present or intending Subscribers to this JOURNAL that no difficulty exists to prevent its being received on the respective days of publication (viz., the 1st and 15th of each month) in any part of Great Britain and Ireland. It is printed in sufficient time to be despatched by the Publisher, Liverpool, or by the London Wholesale Agents, so as to reach the most distant Subscribers and Agents on the above days. Orders sent direct to the Publisher, accompanied by a remittance (if by post-office order, made payable to Henry Greenwood, 32, Castle Street, Liverpool), or to the London Wholesale Agents, Messrs. E. Marlborough and Co., 4, Ave Maria Lane, E.C., will receive immediate attention. Foreign Subscribers and Agents can also be supplied in the same manner by paying the additional postage charged by the Post Office. Orders given through Country Booksellers are carefully executed by Messrs. Marlborough and Co., as above, or by the Publisher, Liverpool.

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

ON ALBUMENISED PAPER AND THE ALKALINE GOLD TONING.

To the Editor.

Sir,—Having of late seen numerous complaints in your Journal and other photographic papers in reference to the above, we beg to offer a short sketch, and to state that the first principal cause of failure is due to the system of cheapness. If the dealer will but give a fair remunerative price for a *genuine* article, we feel certain most, if not all, these complaints would cease. But the purchaser should at the same time state by what process he intends working, and what result he desires.

The second failure is due to weakness of silver bath, and further caused by the addition of too much carbonate of soda to the gold solution, thereby removing or partially dissolving the albumen, causing minute red specks or streaks partially or all over the picture: thus the proof paper is condemned as *bad*. This has always been remedied by reducing the amount of soda.

We prepare the negative and positive Saxe papers *only*, and we will warrant them to be the true Saxe, and purely albumenised. Our salted we specially prepare, and find them equally adapted for the old method (to those who prefer it) as the alkaline.

As a proof thereof we shall be happy to supply the same to purchasers (*vide* advertisement), and to exchange it, if not approved, provided the fault is on our side; and, further, we will personally (within reasonable distance) work it in their presence, at their residence or ours.

In conclusion, we desire to add that, in our humble opinion and experience of some years' constant practice, no other paper is equal to the Saxe. It is uniform in its results and general freedom from metallic spots, &c.; and any desired tone can be obtained at the will of the manipulator.

We in no way, however, wish the above to be understood as deteriorating the value of other papers, as each are good for their particular purpose.—We are, yours, &c., HOPE & CO.

Verulam Terrace, The Grove, Hammersmith, London, W., September 26, 1860.

ARCHER'S FLUID LENSES.

To the Editor.

Sir,—If "W. Anderson," who inquires in the last number respecting the repairing of an Archer's fluid lens, will refer to page 220, No. 80, of the *Journal of the London Photographic Society*, I think he will find the information he requires.—I am, yours, &c., J. N.

October 1*st*, 1860.

[We are obliged for the reference given, where we find that Mr. Isaac Yeoman states that the fluid consists of a mixture of nitric, sulphuric, and hydrochloric acids.—Ed.]

WHY?

To the Editor.

Sir,—I am one of those who like to know "the reason why," and shall feel very much obliged by your answering the following queries in the next number of your very interesting Journal, every number of which I read with much pleasure:—In the Fothergill process, why do some (Ackland, Keene, &c.) use a "*chloride* of ammonia solution" with the albumen? For what purpose? And did Fothergill use it originally?—In your own editorial comments you recommend "citrate or phosphate of soda" to the albumen. Why?—With regard to washing *more* or *less*, it is a matter of opinion, and therefore I make no inquiry. Miss Bahr seems to well wash. I wonder would she have any objection to give her process *in extenso*, through the medium of your Journal. If she succeeds so well as is reported, why not let us have the *modus operandi*—viz., what ingredients she uses, &c.?

Of what *advantage* to photography is the *interesting* discovery of Petschler and Mann? I think, Sir, we should all endeavour to simplify the processes as much as possible, and particularly the *dry* one. Now, the three following all require *re-sensitising*—viz., Taupenot, Petschler and Mann, and *Macnair's* malt one, as he *re*-dips his plate *in* a bath of *nitrate*. Thus we have additional trouble and expense; whereas, in Hill Norris's and Fothergill's we have nothing to do but *develop:* consequently, I am of opinion it is throwing away time and paper trying to make out a *merit* for any other process which requires either re-dipping or re-sensitising. I trust Dr. Norris will give to the photographic world the benefit of his last most important and valuable discovery, which appears the long lost *link* in the chain now recovered. Excuse the length of this.—I am, yours, &c., INQUIRER.

[The addition of a chloride to the albumen is intended to convert any free nitrate of silver into chloride of silver It is alleged that increase of sensitiveness is gained thereby; and certainly the plates keep longer without deterioration than when a chloride is omitted. We recommend the substitution of a citrate or phosphate, because these salts subserve the same purpose as the chloride. But development of the image is easier when these latter are used, and, what is more important, the density of the picture is at least as great as when plain albumen is employed, which is not the case (in our experience) with the chloride. We believe that the lady you mention is at present on the Continent. The advantage of Messrs. Petschler and Mann's discovery is, that plates prepared by their method can be kept *indefinitely*, and are rendered ready for use by a process (simple washing in water) that can be employed under almost any circumstances.—Ed.]

BEGINNING TO "TAKE NOTICE."

To the Editor.

Sir,—The "Babe and Suckling" to whose inquiries in your 122nd Number, relative to portraiture in a sitting-room, you were kind enough to reply, is developing into a promising child. He has cut his teeth, and was just getting on his legs; but, having had an attack of measles, or some such spotty complaint, on his face (photographic), he has had a relapse, which has again plunged him into a sea or rather bath of troubles. Listen to his complaints, prescribe a remedy, and merit the thanks of

October 11, 1860. THAT BLESSED BABY.

1. That side of the face next the reflecting-screen has a mottled appearance in the finished picture.

2. The pictures latterly are dotted over with very minute ragged-looking holes; and the collodion film, when sensitised, seems weak and not creamy.

3. Why don't you give us a glossary of mischances and failures, dedicated to photographic dunces, who, I guess, form the vast majority of your readers (no offence)?

[1. Do you take glass positives or negatives? We can assign no cause for the mottled appearance from the data with which you furnish us.

2. The holes may arise from some fine precipitate in the bath—remedy, filtration; or from the bath not being saturated with iodide of silver—a plate left in for an hour or so will cure that; or from preparing your developer with common instead of distilled water. If you are taking glass positives, the film should *not* be creamy; if negatives, add more iodising solution.

3. Because we find it better to meet actual difficulties when they arise than to anticipate failures which may never occur. You are quite in error as to the supposed class of the majority of our readers.—Ed.]

FREE NITRATE OF SILVER AND DRY PLATES.

To the Editor.

Sir,—I cannot reconcile with Dr. Hill Norris's theory—that free nitrate of silver *retards* the sensitiveness of iodide of silver in our processes—the fact that Fothergill plates, from which all free nitrate has been removed by copious washing, are less sensitive than those which are suffered to retain a very considerable trace. Am I not right in speaking of this last as a fact? Can you explain why, in Mr. Petschler's process, the plates do not admit of being stained during development?—I am, yours, &c., F. C.

[There is no antagonism in the two cases. All nitrate of silver left on the "Fothergill" plate is certainly combined with the albumen and what it holds in solution prior to the final washing; and moreover, it is found that the addition of an alkaline chloride, phosphate, or citrate (thus ensuring the absence of the last traces of *free nitrate* of silver), increases the sensitiveness.

We are not prepared to admit that there has been any definite proof of the alleged fact that Fothergill plates, from which free nitrate of silver has been as much as possible removed from them prior to the addition of the albumen, are less *sensitive* than others. It may be so, but the actual proof is wanting; for difficulty of developing the image is a very different thing from its absence, which may be apparent only and not real; and there are many facts, which are indisputably established, rather tending to indicate that an impression is really present, requiring only judicious treatment to render it visible.

We do not precisely comprehend what you intend to convey by the last query. Do you mean to assert that it is impossible to stain one of Mr. Petschler's plates?—Ed.]

THE OPTICAL GHOST.

To the Editor.

Sir,—In the illustrations of the interesting article on the late solar eclipse, contributed to your Journal of September 1st, by Mr. Charles Heisch, there appears a second or ghost image. It seems to me to be simply what we call the optical ghost, which presents itself very distinctly in a darkened room when you try to get the focal image of a candle on the wall by means of a lens. You have only to fancy the moon the candle, and the comparatively darkened earth the dark room. You will then have very little difficulty in tracing a great similarity. Some persons may ask—How do you account for the ghost's non-appearance in No. 1 diagram? The answer is, simply, that ghosts prefer the dark—or, in other words, the room or earth was not dark enough to show up this faintly-illuminated image.—I am, yours, &c., H. FRANCIS.

[We believe that what our correspondent denominates the *optical ghost* is only existent when an imperfectly-constructed lens is employed. —Ed.]

ANSWERS TO CORRESPONDENTS.

Erratum.—In the report of the meeting of the North London Photographic Association, in our last, 30th line from foot, for "construct" *read* "constrict."

M. Noton.—Received with thanks.

Photo.—About a week in summer.

Martha.—They are now under review; particulars in an early number.

J. (Torquay).—You should visit Dartmouth: you will find there several subjects of the class you seek.

Thomas L.—We cannot recommend the practice you mention, as it throws the nitrate bath out of order.

Brentwood.—Good friend, you have forgotten to let us know where to address to you. As you are not a resident there, the name of the place alone is not sufficient.

Gavazzi.—We cannot give you the names of Italian photographers, but have no doubt you could obtain the information from Messrs. Colnaghi and Co., Pall Mall, London.

3. Copying by contact involves the necessity of adhering to the same *scale* as the original. We see no objection to intensifying a dry plate by the bichloride of mercury, if you find it needful; but we scarcely think this will be requisite with a dry plate.

J. R. F.—We cannot undertake to do what you request. We have no time to spare, and we do not consider that the principle involved is sound; consequently, are not inclined to waste materials and, what is more important, labour over what we think ought not to succeed.

Stereographs.—Several correspondents who have favoured us with specimens for review will please to understand that they are in course of undergoing that process, unless they have received *private notes* explaining the defects which preclude our noticing them in our columns.

B. C. A.—Having added the "bottoms" of your partly-used bottles of collodion together, thin the collodion with a sufficiency of ether three parts, alcohol one part. It does not require any more iodising solution; and the quantity of the above mixture depends upon the fluidity required.

Acme.—We have every reason to believe that the process adopted in toning the beautiful specimens you name is the *simple alkaline gold toning*—indeed we have no doubt of it. The reason that you have been unable to produce similar tones may be in consequence of your not having used the same kind of *paper*.

G. F. W.—1. Yes; but the amount of subject included will be very small—in other words, the *angle of picture* will be very limited, the scale of delineation being great.

2. We do not quite comprehend this question: you do not say to which *figure* you refer.

3. Maxwell Lyte's.—Thanks for your good wishes. We do not think, however, that there is any real demand for what you suggest, but you can talk to the Publisher about it if you like.

C. H.—Copying from an engraving upon a dry plate by superposition and exposure in the pressure-frame is not very frequently resorted to, for the following reasons:—

1. Liability of injury, both as regards the plate or the engraving, or both.

2. In order to get the best effect this way it would be needful to wax the engraving, to render it more transparent, as the inequalities of thickness and grain of the paper would otherwise interfere with the perfection of the results.

J. H. Slater.—The diameter of a view-lens has very little to do with the best position for the stop, which is determined by the *oblique* pencils of rays; for on the direct central ones the stop exerts no influence, except to limit the diameter of the pencils. The best position is most easily ascertained by experiment, and this has most probably already been done by the optician who made your lenses. The further from the lens the stop is placed, as a rule, the flatter will be the field, but the more the distortion at the margins of the picture, and *vice versâ*.

No Chemist.—Thirty to thirty-five grains nitrate of silver to the ounce of distilled water—in fact, an ordinary collodion sensitising bath. The albumen:—White of egg three parts, water one part, ten minims of ammonia, and two grains of chloride of ammonium to each ounce of the above, well frothed and filtered. The ordinary pyrogallic developer, or pyrogallic acid two grains, citric acid one grain, water one ounce, or gallic acid to saturation. A few drops of nitrate of silver solution to be added to the developer just before use. An iron developer is not applicable.

*** We have been obliged, from want of space, to postpone No. III. of Mr. C. Jabez Hughes's admirable series of articles—*Observations on Albumenised Paper and Alkaline Gold Toning*—till our next number. From the same cause we have also been compelled to omit a number of advertisements.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 129, Vol. VII.—NOVEMBER 1, 1860.

The unfair and ruinous competition with the photographic publishing trade carried on by the Department of Science and Art at South Kensington, to which we referred in our last, has elicited expressions of opinion singularly in accordance with our own view of the subject from several correspondents located in various parts of the kingdom, while in no single instance have we received anything approaching to an attempted defence of the conduct of the "authorities" in the establishment of which we complained. From Mr. Coningham, M.P., we have received an article on the subject, written before the appearance of our last leader, but with which we have been favoured in consequence. Mr. Coningham's arguments coincide in a remarkable manner with those which we advanced on the various points involved in the question at issue, as our readers will doubtless perceive on comparing the two—an opportunity of so doing being afforded by the publication of Mr. Coningham's article in the current number. It is always gratifying to find one's view of any debated question corroborated by others who have also carefully considered it, but still more so when such an occurrence arises amongst those who from their position and energy are likely to afford material assistance in procuring a remedy for the evils sought to be removed. We have already remarked that the attempted interference with the legitimate business of photographers will, if not duly checked, in all probability prove but the precedent and stepping-stone to still further aggression directed against those following other branches of business. It therefore behoves all persons, whether personally interested in photography or not, to aid in putting a stop to the injustice. But we believe that the proper course of proceeding would be for the photographic profession to take the initiative in resistance.

Amongst the curious signs of the times in which we live we may now surely reckon the wide diffusion of the race of photographers. It is indeed not a little difficult to state positively where they have not been found. China, Japan, the Philippine Islands, the Holy Land, Egypt, amongst the warmer latitudes, have all furnished their records photographic. New York, the Canadas, the Alps, have been some of the colder regions explored. Besides all these we have illustrations of Russian, French, Italian, German, and Spanish scenery, both urban and rural. We have just heard of a new series of a highly-interesting character from Cuba, in which the various operations carried on in the sugar and coffee plantations are faithfully portrayed. Lastly, we have been informed of the safe arrival in Iceland of a gentleman who accompanied the North Atlantic Telegraph Company's expedition in the *Fox*. We learn, too, that he has taken numerous stereoscopic groups of the Icelanders, as well as views of different parts of the island. We believe that he received instruction in photographic manipulation from Mr. Quin.

Our readers are already familiar with the application of photography to the purpose of recording the variations in terrestrial magnetism, from a perusal of papers on the subject by Mr. Glaisher, read at the meetings of the Blackheath Photographic Society. At the last ordinary meeting of the Manchester Literary and Philosophical Society the President exhibited a slip of paper which he had received from Professor Thomson. On the paper was printed by photography the line indicating the various changes of atmospheric electricity which took place at the observatory of Kew during twelve successive hours. Much interest was excited by witnessing one of the first fruits of Professor Thomson's beautiful instrument. The paper indicated a series of very rapid oscillations, about one per minute, of the intensity of atmospheric electrical force.

In the report of the last meeting of the South London Photographic Society, which will be found in the usual column, we were not a little surprised at finding it stated, in reply to the question, "How they could tell when the axis of a lens was central?" that it was a "trade secret—one of the important secrets only known to a few!" Surely the gentleman who made such a reply must have been joking. However, be that as it may, we cannot possibly allow such an assertion to appear in the Journal under our supervision without comment, feeling assured that there are many of our readers quite sufficiently acquainted with the subject to have a laugh at our expense were we to let it pass unnoticed. Trade secret or not, then, we must certainly explain the method of ascertaining the point, which is as follows:—

While the brass mounting of the lens is still in the lathe, and the lens itself inserted, a lighted candle is placed at a distance, in the direction of the axis, without any particular regard to accuracy of position. A piece of white card is then held behind the lens, so as to get the image of the flame in pretty correct focus: then by causing the lens to revolve in the "mandril," by simply working the "treadle," it will be at once seen whether the lens axis is properly centred; for, if this be the case, the image of the flame will remain *perfectly stationary*, notwithstanding the rapid revolution of the lens—if not, the image will have a rapid flickering movement, the amount of which *increases* in direct ratio with the eccentricity of the axis. The same test applies also to the double combination; but in this case any eccentricity is of far greater importance, because infinitely more detrimental than in a single combination. In the latter slight eccentricity is of little consequence; in the former it would be fatal to anything like correct performance. It must be borne in mind that, in examining a lens for this quality, after it has been removed from the lathe in which it has been finished, care must be exercised in order to ensure its being properly screwed into its place of adjustment, as otherwise the error of adjustment in position will give the appearance of its being improperly centred; and here again the portrait combination requires more care than that for views—the test applied being, in fact, to the *axis of the lens* with reference to the *centre of motion*.

We have to remind our readers that the time is approaching when such as may contemplate contributing to the various photographic exhibitions should commence making their preparations. The London Society will, we believe, as usual,

make arrangements for opening in January, and the Scotch Society in February next. Our Manchester friends have fixed the period of the meeting of the British Association for their display, so that a wide interval will elapse between these events—certainly not to the disadvantage of either. From an advertisement in another page it will be seen that all pictures intended for the next Exhibition of the Architectural Photographic Association should be sent to the curator, Mr. Henry Moody, 9, Conduit Street, W., on or before the 5th instant.

It has frequently been supposed that the Photographic Society sustains a loss in being obliged to hold its exhibition during the winter months, but we are certainly not convinced that there is any real ground for this idea; for besides thus avoiding competition with many other exhibitions of a class more attractive to the general public, such as those of the Water Colour Societies, the Royal Academy, &c., we must not forget that photographs are objects that require very close inspection in order that they may be appreciated, and this of itself alone involves the devotion of a considerable amount of time. Now in cold, dull weather, when there is not much attraction out of doors, a large number of people not otherwise likely to visit a photographic exhibition will probably be induced to do so, and, as the experienced coquette used to remark, "if they can only be induced to *look*, conquest is sure to follow."

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 14.

Photographic Journals are expected to contain information conveyed in a light and easily-digested form, and are, therefore, placed upon the breakfast table side by side with the morning papers and other periodical literature. One opens the Journal expecting to be refreshed by a perusal of what the brethren in the art are doing, and hopes to find everything going on comfortably. It occasionally happens, however, that these expectations are not fulfilled, and that a paragraph meets the eye which is decidedly unpleasing. This was the case with an address lately given by the President of the Chorlton Photographic Association, in which our own name appears in connexion with collodion. One principal object of the address is to complain of the imperfect state of the chemical science of photography at the present time. Now, judging from our own experience, we should be inclined to say that such addresses exercise a prejudicial effect, and that they tend very much to lessen progress. Something, no doubt, depends upon the temperament of the individual, since there are sanguine spirits who refuse to see any difficulties when they are interested in an undertaking. Minds of a different turn, however—and we suppose that the Chorlton Association includes some of these—require encouragement, and the only sure way of urging them forward is to tell them that they are gradually nearing the mark, and by sustained efforts may eventually hit it. Whilst allowing that there are many things in photographic chemistry of which we are yet ignorant, it is consoling to us to reflect that we know more than we did formerly, and that ten years hence will probably see us still further advanced. Mr. Griffiths will pardon us for taking up this question and endeavouring to show that it has two aspects, and admits of being seen from a cheerful as well as from a desponding point of view.

Supposing the president of a medical society were to open a session by an introductory lecture on the present unsatisfactory state of our knowledge of medicine, no doubt arguments in support of his assertions would soon be forthcoming. It might be said, for instance, that although the healing art had been practised since the days of Hippocrates, the true principles upon which it ought to be conducted were even now imperfectly understood. Patients in fever, formerly treated by low diet, were now "supported" by stimulants until the poison had been burnt off and exhausted. Other patients, labouring under diabetes, or a flow of saccharine matter, were by some denied the use of sugar and by others almost surfeited with sugar, and yet, strange to say, the patients were in both cases stated to have experienced relief. Such perplexing differences showed clearly that there was not that concord amongst medical men which could be desired.—Now, the reply to an address of such a kind would be, that we must not expect too rapid an advance in medicine. The profession is one of great difficulty and embarrassment, so that we are satisfied if we get forward by a single step at a time, and are content to observe differences of opinion lessening, even although they do not immediately disappear.

To compare the study of photography with that of medicine may by some be deemed an exaggeration, and doubtless it is so; for the conditions affecting the issue of an experiment are vastly more complex in the latter case than in the former, and it requires more shrewdness and discrimination to trace effects to their real causes. Photography, however, is remarkable for the minute and patient attention it requires to unravel its mysteries. This even chemists themselves acknowledge, and desire that it should be separated off as a distinct branch of the science, occupying the undivided attention of those who pursue it. Without the exercise of extraordinary care, observations in photography are of small value, although they are given on the authority of a good name. Dr. J. Schnauss, for instance, is known as a skilful chemist; yet when he conjectures that all preservative organic substances act in the same manner, we cannot but refuse our assent to such a statement. If the doctor were to investigate the subject with that care which he gives to his more purely chemical researches, he would see that it is not so. And supposing him to be wrong in his ideas, of which we entertain no manner of doubt, then his subsequent remarks on the vanity of little people who hasten to rush into print are entirely out of place.

When photographic societies make their annual report, there is cause for congratulation if a single new principle has been enunciated during the session, or some annoying failures traced to their proper source. Other matters perhaps have not been settled to the satisfaction of all, and lookers-on are amused at the perplexities of the photographers. Who shall decide, say they, when the doctors disagree? We reply that *time* will decide, and that those who are confident as to the goodness of their cause, must wait quietly and expect in the end to be established. Latterly we have been reading M. Monckhoven's work on photography, and are surprised to find that in France they do not adopt Mr. Hadow's views on the composition of pyroxyline. This, however, will not disturb us in our previous convictions as to the soundness of those views: on the other hand, we continue to believe in them most fully, and expect that all will eventually acknowledge their truth.

Again, the value of researches in photography is underrated by those who refuse to see in them anything more than a mere formula or recipe. This formula they try, possibly without success, and if so, they conclude that the whole argument which led to its construction was unworthy of attention. A deeper study would, perhaps, have shown them that it contained more than they imagined, and professed to explain not only what should be done, but what should not be done. For instance, on consulting the index of a volume now lying before us, we find an article, by Mr. Sang, on photographic varnishes. Mr. Sang speaks of six different varnishes which he finds unsuccessful, but cannot tell us the composition of the one which answers. Now, some would condemn this communication as incomplete and useless, but we do not agree with them in so thinking. The analysis of a varnish is uncertain; and next to a formula which succeeds, the second best thing is to know the composition of several others which do not succeed. As with varnishes, so with collodion: it has become almost a fashion to say that we understand very little about it; and that no formula, however carefully followed, will give uniform results. Let the operator, however, dismiss from his mind all ideas of actual weights and measures, preferring to depend upon a theoretical study of the subject in all its bearings, and we can promise him that he will be in a position to prepare any quality of collodion that may be demanded.

Mr. Griffiths will not see, in these comments, evidences of a hostile spirit directed against himself, but rather the sentiments of one who, having devoted some years to the study of photography, is unwilling to believe that the science is in the deplorable state represented. All labourers in this department of chemistry are sensible of the difficulties which stand in their way, and will urge them in extenuation of the charge of want of progress.

OBSERVATIONS ON ALBUMENISED PAPER AND ALKALINE GOLD TONING.

By C. Jabez Hughes.

No. III.

Albumenised Paper.—Photographers are not agreed whether the best albumenised paper is that which has the highest gloss. The majority certainly run after the glitter; but the old proverb holds good again, for the most perfect paper cannot be made to take the

same high glaze that some inferior ones do. This rage for gloss has a great tendency to drive albumenisers to adopt some of those tricks they have recently been charged with — of using gelatine, stale eggs, and other objectionable means to produce this strong glaze. Admitting that albumen-brilliancy is desirable, its production should only be by legitimate means. An intensely high glaze is not the only thing needful in an albumenised paper. This fact cannot be too strongly insisted on; and photographers must be made aware that albumenisers cannot give any glaze they please indifferently on all papers, and that some very good papers, though taking a very high surface, will not compete in that respect with the commoner and, in other respects, inferior French papers.

Albumenising paper is an operation requiring great care and *knack*. In consulting with several who do it on a large commercial scale, I find they have few or no secrets. Their success lies in that careful manipulation acquired only by considerable practice and experience. For the supply of eggs they depend on the egg merchants; though I know one party who uses only fresh-laid eggs, and he charges many of the defects of the common albumen to the foreign eggs being packed in lime, which, permeating the porous shell, acts on and injures the albumen, the presence of the lime, according to the statement, being evident in the taste of the albumen. The quantity of eggs consumed in preparing photographic paper must be very great. In one establishment I recently saw a box containing 1100. I was assured that two of these were used every week. This would give upwards of 114,000 per annum used by this person alone!

When the highest glaze is wanted it is the practice to add no water whatever to the albumen: the crystals of chloride of ammonium or sodium are added and beaten up with it, and thus made to dissolve. When it is in the condition to be used — some use it when a day old, and reject it at the end of a week; some begin to use it only when it is a week old — it is placed in dishes larger than the whole sheet of paper: the sheets are carefully floated, and then hung up to dry in a warm place. The rooms where the albumenising is conducted are kept at a high temperature, it being a most important circumstance to dry the sheet as quickly as possible after taking it from the albumen.

Chlorides of sodium and ammonium are each used, and it is believed that there is not much difference. On plain paper the nature of the chloride is of consequence in affecting the tone; but with albumenised paper it is thought that this effect is practically ignored by the influence of the large amount of albumen. Chloride of barium I do not find in general use.

There is a considerable agreement about the quantity of salt to be used. From ten to twelve and a-half grains per ounce is considered the proper quantity. One party, however, uses fifteen grains. The sixty-grain silver solution will therefore be about the strength required for nearly all papers.

For those who wish to albumenise their own paper, the operation is as follows:—Obtain as many eggs as are required ounces of solution to fill the dish to the depth of half an inch. Break the eggs individually in a cup, being careful not to disturb the yolk; then extract the germ, and pour the albumen in a large vessel to be used for beating it up. By treating each egg alone, any one which may have the yolk broken, or that is not good, can easily be rejected, for one bad egg may spoil the whole batch. Next add chloride of ammonium, ten grains for each egg. Dissolve the chloride in as little water as it will take up, and add it to the albumen: beat the latter till it all becomes a stiff froth, and not a drop of fluid remains. Allow it to remain for twenty-four hours, then pour it through a fine muslin into a shallow dish. Float the paper carefully on the albumen so as to avoid air bubbles: this is the most delicate operation, and great *knack* is required to do it properly; for if an air-bubble once occurs, although it may be removed, it will always show in printing, therefore the sheet must be so laid down that none be formed. The length of time the sheet must remain on the albumen depends on the kind of paper. Generally it is from sixty seconds to two minutes. If the paper remain too long the albumen sinks deeply, and the surface dries dull. In lifting the sheet off as much skill is required as in laying it on. It must be lifted with one steady regular motion, any hesitation or stopping causing a streak or series of streaks. The sheet must be suspended by *two* corners, so that it may drain and dry in a uniform manner. When the albumen is set the sheet may be dried by the fire: the quicker it is dried the greater the glaze. When dry the operation is, strictly speaking, finished, and the paper ready to be silvered for printing; but, as usually prepared for commerce, it passes through another operation — that of *pressing*.

Formerly it was thought necessary to smooth the paper with a hot iron to coagulate the albumen prior to sensitising, and as this was inconvenient on a large scale, it was sent to the *hot-presser's*. Though it has since been discovered that the silver solution itself sufficiently coagulates the albumen, yet the pressing — now cold pressing — remains.

This process the albumenisers cannot manage themselves, but send the paper to the card glazers', who, for a small charge, do it for them. The operation is simple. Two highly-polished steel plates, kept expressly for this work, are provided, and two sheets of albumenised paper, back to back, and albumenised surfaces to the steel plates, are placed between them. They are then put under heavy rollers and submitted to powerful pressure. This takes out the *curl* the paper gets from albumenising, and causes it to lie flat. It also communicates a peculiar gloss and apparent fineness of surface, which is, however, purely artificial, and disappears when wetted; and it is worth while considering whether photographic paper should pass through this operation. It is a question of advantage and disadvantage. By the process of pressing the paper loses its *curl*, acquires a delusively fine face, and lies invitingly smooth in a tradesman's drawer; but for practical ends its sole and only recommendation is, that it lies more easily on the silver solution.

The disadvantage of the pressing is, that the paper passes from those who understand it and are interested in keeping it clean and perfect, into the charge of careless boys, who handle it with dirty hands; that particles of dust and dirt that adhere even to polished steel plates are ground into the surface; and that often the albumen itself is much injured in the rolling, sometimes literally crushed, to the entire prevention of getting a good print, through too much pressure being used. Is it desirable, for so small an advantage, that so much risk should be run? I think not. Some persons who prepare a great deal of paper have set their faces against it, and will not have their paper rolled. Others laughingly say, "the public like it — are tickled with a shining face; that high glaze, like charity, covers a multitude of sins; that though it is little else than a sham, let them have it who know no better." The grain and structure of a paper is very much opened up in albumenising, so that its nature can be judged; but, if it be pressed, an apparent fineness is communicated that cannot be relied on, and one means of forming an estimate is removed. Nearly all the finger marks—how frequently a fine and unnecessarily perfect representation of the whole five digits!—are attributable to handling with dirty hands during the pressing operation.

I strongly recommend photographers to discontinue the use of rolled or pressed paper.

When the printing is all over, and the picture mounted on card-board, *then* is the time to press it, and take full advantage of the fine surface to be communicated.

Is gelatine used by albumenisers to give increased glaze to their papers? The assertion is frequently made, and there may be truth in it; but, from inquiries I have instituted in very many quarters, I can get no evidence of it. The nearest approach is the practice, said to be adopted by one party, of sponging his sheets of paper, first with a weak solution of gelatine, then having them pressed, next albumenising, and finally pressing again; but this operation is only equivalent to giving the paper an extra sizing to create a harder surface, so that the albumen, by being more superficial, will give greater glaze. Those who adopt adulterations generally do it for cheapness; but any paper passing through a double operation of this nature must be enhanced in price.

I have certainly met with papers, albumenised in France and sent to this country, that have had a very suspicious odour; but I think the practice of all respectable parties in this country is to use albumen only. Albumen is, however, used in different states. When newly prepared it does not give such high glaze as when it is older. If albumen prepared yesterday be used to-day, it will not give much glaze—it sinks into the paper: to-morrow it will do better: in three or four days time it will be in first-rate order. This, however, depends on temperature and period of the year. One of the troubles of the albumeniser is the keeping his albumen in order, and when it is in its best condition, to use it up as rapidly as possible. Some persons keep their albumen for a fortnight or more before they use it—the object being to concentrate it, to evaporate the water from it, and make it thick; and in this state it will give a very high glaze upon even a porous paper. But this is certainly pushing things too far, and the paper will show it; for instead of being white it will be decidedly yellow, from the thick layer of decomposed albumen. When paper prepared in this manner is moist, both the colour and adhesiveness of

surface would lead a person to think that *gelatine*, and not albumen, was the substance employed; and in this way I account for the outcry, which should be against decomposed, stale albumen, and not against gelatine. This is but an instance of extreme means being adopted to minister to the rage for the intensely highly-glazed paper.

I think the knowledge pretty generally exists now how to obtain the highest glaze by perfectly legitimate means.

It is, in the first place, to secure good albumen; to add no water to it, or at most barely enough to dissolve the salt; to beat it so well that it shall not hold in suspension any membraneous portions causing bronzed lines; to use it when it is in its best condition—not so old as to be thick and yellow, nor so new as to appear diluted with water; to lay the paper on the albumen the shortest time consistent with obtaining a uniform film, and to dry it as quickly and as uniformly as possible afterwards. These are the conditions to albumenise paper well; but, simple as they may appear, it requires great experience and tact to apply them to practice. The albumeniser is always troubled with his papers,—different samples requiring slightly different management. Speaking generally, the English papers absorb the albumen and become rough on the surface, drying without much gloss. The Saxe papers may by dexterity be got to receive a very fair glaze; but the Rive seems merely to hold the albumen on the surface, and its highly-varnished appearance would hardly be judged as being obtained from the same treatment that gave only a moderate glaze to the German, and even a dull look to the English paper.

OBSERVATIONS IN REPLY TO THE REPORT OF THE SELECT COMMITTEE ON THE SOUTH KENSINGTON MUSEUM.

By William Coningham, M.P.

"Whatever rules may be adopted with respect to photographing pictures or works of art belonging to the public, the department should not enter into competition with the general traders."—*Mr. Joseph Locke's rejected amendment to the Report.*

Now that the doors of Parliament are safely closed, the evidence upon which was founded the report of the select committee on the Kensington Museum has been tardily placed in our hands. I deliberately assert that had that evidence been attached to the report, the instalment of £17,000 voted for the alterations at Kensington, with an "approximately estimated" expenditure of £27,000, would then with difficulty have been carried through the House of Commons.

The history of the Brompton boilers, the annual cost of which in coal alone is admitted to be "monstrous," may be thus briefly told. Founded by the Great Exhibition Commissioners of 1851, repudiated by Sir Benjamin Hall on behalf of the Board of Works, erected by "orders" from Sir William Cubitt "out of benevolence, as it is said, to the commissioners," of whom Sir William was himself one, the Brompton boilers were built, and built of corrugated iron; and it is now admitted on all hands that ever since their erection they have been a nuisance to every one connected with them. Impossible to be warmed in winter with ever so "monstrous" an amount of coal!—leaking, as Mr. Cole "impartially" admits, "everywhere," and at an original cost to the State of £15,000, with prospective illimitable expenditure *in futuro*, the boilers were ultimately handed over to the Department of Science and Art. By the removal of the schools from Marlborough House the country was saddled with some additional thousands. But the Commissioners of Patents were already in possession of a portion of the edifice, and very properly objected "to the taking of any fees at the doors" of a public museum. Unlike the officials of the National Gallery, the Patent Commissioners refused, point blank, to levy toll on either rich or poor, and demanded and obtained a separate free entrance.

The department, therefore, came into possession of the iron building with its "contingencies;" but it was opened to the public according to South Kensington Museum rules, which are framed in direct opposition to the resolution of the Trustees of the National Gallery, "that arrangements for the easy and free access of the public at all times and under all circumstances to the pictures of the National Gallery—*are absolutely essential.*"

The constitution and pretensions of the Kensington Museum are exceptional, and its assumed functions entirely differ from those of the National Gallery and the British Museum, which appear to be limited to the public exhibition of works of science, of art, and of literature, or at all events to a proper control and direction in their use. The Kensington Museum, on the contrary, professes to superintend, to direct, to teach and give prizes, of which it is, at second hand, the manufacturer, to compete with the general trader in his own special business; in short, to interfere in every possible manner with all that concerns the art and scientific schools connected with the department. It is, moreover, a scarcely disguised advertising centre for all inventors, traders, and manufacturers, and an active competitor in an artistic branch of industry, and thus the department has come into collision with the private and legitimate trade of the country, which finds itself crushed with an instrument, to the production of which it has been compelled to contribute, in the form of imperial taxation—a system calculated to sap public morality and the independent spirit of the people. The sum of money in question may appear small in amount when contrasted with the national expenditure; but in the consideration of this subject an important principle is involved, namely, "how far, if at all, is it expedient for the Government to trench upon private enterprise either in the training and education of the people or in the trade and manufacture of the country?" The aim and object of Mr. Cole may best be defined in his own words, wherein he explicitly states that "by these means we place objects of the highest art within the reach of the poorest person." But why alone "objects of the highest art," for which the poor do not care, and which they cannot appreciate? For the same reasoning would equally apply to objects for which they do care, and which they can appreciate: such as beef, beer, warm clothing, and good wages. Again, if the possession of, or access to, objects of "the highest art" be so desirable, why remove the national pictures from Trafalgar Square, where the public are admitted gratis, to the Museum of Kensington, where, on three days in the week, the poor man, should he desire to see those works of high art, to the purchase of which even he or his forefathers have in some shape contributed, has to pay a fee of sixpence at the entrance door? With such facts before us the hollowness of these high-sounding phrases is transparent. The Kensington Museum system, in my opinion, contains within itself the germ of almost every objectionable form of Government interference with private enterprise, gradually substituting, on a colossal scale, the unhealthy and exploded principle of protection for that of salutary competition and free trade.

Mr. Cole's plea for the photographic reproductions is, that "either the department must be a trader or the public cannot have the copies"—an argument which would justify the interposition of the Government in every case in which the public could not obtain that which it desired, a proposition so monstrous as to refute itself; and I assert, moreover, from the experience we have had of the working of all Government departments, that, in the long run, the public would be far better supplied by private enterprise than by any artfully devised scheme of Government administration.

But the Department of Science and Art does not confine its trading operations to photography, it extends its greedy clutches to the electrotype process, and has its own school prizes made by its own manufacturer; for in this case, it appears, according to Mr. Cole, to be "necessary to have a man in whom you have confidence," otherwise he might "depreciate" the work. But why should Mr. Cole object to the work being made cheap and accessible when in the next line he proposes "to place objects of the highest art within the reach of the poorest person?" As a saving clause this Protean head of the department professes not to enter into "the trade" of this reproduction (electrotype) "as we do in the case of photographs." Again, I ask, why not trade in electrotypes as well as in photographs? Has the department no other near relative in that particular line of business?

Next as regards the salaries of officials at the Kensington Museum. The annual expenditure of the department amounts to no less than £60,415; of this sum £33,675, or more than half, is devoted to the salaries of officials, yet I find Mr. Cole bitterly bewailing the inadequate remuneration of the purchasing superintendent of the art collections, whose salary, now amounting to £460, rises to £500. "His case," says Mr. Cole, "has been brought before the Treasury repeatedly by the board; but owing to the suspicion we are under at the South Kensington Museum, the Treasury have declined to consider his claims." Mr. Cole further adds that, "in every purchase he (the superintendent) has made, he could have sold them again at a very increased profit, owing to his keenness and judgment. I think he is most unjustly treated." Mr. Cole thinks this gentleman ill used at a salary of £460, rising to £500; and that he would do wisely, "if it were merely a question of making money," to resign his office at the Kensington Museum, "as in a very few years he would make his fortune as a dealer;" but having "grown up from a student in the atmosphere of the South Kensington Museum," and out of "regard" for that

alluring establishment, where more than half the expenditure goes to defray salaries, this ill-requited purchaser still consents to remain.

Mr. Cole affirms that "the decision to purchase" an object "is never made except with the perfect conviction" that it could "be sold for more money than it is offered for!" As if the rapacity of the dealer, or the market price, which constantly fluctuates with every caprice of fashion, not the excellence and intrinsic worth of the object itself, were the real test of fitness or eligibility.

When pressed upon the question of agency or brokerage, Mr. Cole says that it would be "impossible" for the gentleman holding a similar office at the British Museum to perform the duties of "purchaser" for both institutions, and begs the committee "to conceive the case" of simultaneous sales at different auction rooms, and then asks whether "the same individual" could possibly represent both establishments? thus presenting the dilemma of one person being in two places at the same time. Yet a few lines further on Mr. Cole admits that the official "purchaser" himself very seldom buys; "we," that is the British and Kensington Museums, employing "the same buyer!" who, by the way, is also a large dealer, and ought, on that ground alone, to be disqualfied for the office.

If the department be happy in its self-sacrificing purchaser, it is still more fortunate in the dealers with whom it is destined to traffic; for, while the purchases on behalf of the museum are made on the ordinary selfish and mercantile grounds—by "haggling in the market"—this doubly-fortunate institution has succeeded in creating a novel and disinterested race of dealers in *vertu* who sell their wares, not like other vulgar traders, for profit, but at a tremendous sacrifice, actuated solely by a "regard" for the interests of the Kensington Museum.

I might enlarge upon a variety of edifying disclosures to be found in the blue-book; such, for instance, as the overbearing and encroaching character displayed by this board—for it is a "board"—in its dealings with the Architectural Society, abruptly refusing, in answer to their earnest request, to take any "temporary measures" by which to avoid disturbing the valuable collection of that society. In reply to their application, the architects received an unceremonious "notice to quit," or to make over the collection and the management, on loan, to the Museum, forcibly reminding one of the ingenious *escopetero*, in "Gil Blas"—half bully, half beggar.

These are the grounds upon which I rest my opposition to the South Kensington scheme; and if the statement which I have here submitted for consideration be really characteristic of the principles on which the Department of Science and Art is conducted, then I shall be fully justified in protesting against the conclusions contained in the Report of the Vice-President of the Council and his Select Committee, and in appealing to the better judgment of the House of Commons, and to the good sense of the English people.

ON THE PHOTOGENIC ACTION OF COLOUR.

By Mr. S. Clarke.

[Read at the meeting of the South London Photographic Society, October 18th, 1860.]

The paper which it will be my pleasure to bring before you tonight is collected from facts which have been presented to my notice from time to time, and would, perhaps, if thoroughly investigated, throw at least some light on the probability, or otherwise, of the production of photographs in natural colours.

Every one using the camera must at times be struck with the surpassing beauty of the image on the ground glass, where every tint and varied hue is presented to the eye as a charming little picture, almost surpassing Nature herself. With what reluctance do we at times remove that glass, knowing, as we well do, that at most we can only secure the uncoloured shadow! What, think you, would be our joy if we could but secure those lovely tints!—with what pleasure would we plant our camera to greet the morning sun, and at evening to secure his parting rays! This much by way of introduction. * * *

At times, in developing with pyrogallic acid, parts of the picture will come out coloured, but invariably fade on drying. And during the past summer, in experimenting on the Fothergill process, I have occasionally met with a picture with the sky of a fine azure tone and the grass and foliage of a rich green, and, unlike the results in the wet process, these remained permanent after drying. These pictures were taken in dull weather, and the colouring seemed to arise from prolonged development.

Satisfactory indeed it would be to obtain a coloured picture direct in the camera; but if it be true that substances which reflect a certain colour will, by transmitted light, stop out that colour and allow the colour which is complementary to pass, then might we expect to obtain a negative from which we might print any number of pictures with the colours as they are in nature. In studying this I have been struck with the coincidence of this and the picture formed on the retina of the eye; for, on looking at a colour for some little time, and then removing it, the colour complementary to it will be seen. Thus, if a red wafer be placed on a piece of white paper, and you fix your eye on it for a few minutes or so, and then remove it, a green spot will be seen; a blue one would produce orange; and so on. Now, looking at the eye from a chemical point of view, is it not possible that it may be supplied with a substance capable of being impressed by these different colours? and if so, we might inquire into the nature of the impression and the substance in which it is produced. This I give for what it is worth, but, as I wish to abstain from any speculative ideas, I shall leave the subject and proceed to notice the more practical part of my paper, and shall ask your attention while I show the result of a series of experiments conducted by me during the early part of last month.

Experiment 1.—A disc of cardboard was divided into six concentric rings or bands, and coloured with the three primary colours (blue, red, and yellow), and their complementary colours (purple, green, and orange), and a photograph taken of it, which resulted in the blue coming out white; the red dark grey, and the purple light grey; while the remaining colours, yellow, green, and orange, made no impression on the sensitive film.

Experiment 2.—A transmitted positive was taken from a negative, on which three strips of coloured glass were fixed, the result being no action through the red and yellow glass; and it was evident, from the appearance of the picture, that the blue rather retarded than accelerated the action of light.

Experiment 3.—Two busts were placed in a box coloured grey inside, and so as to allow of no direct light falling on them (and arranged so as to produce as much shadow as the diffused nature of the light would admit), and a photograph taken of them, when the shadows were reproduced in a very correct manner, producing none of those black and white patches so often seen and so much disliked.

Experiment 4.—The foregoing, repeated with a blue light, reflected into the shadows, and which resulted in the entire destruction of all harmony and half-tone, producing little besides a white patch with the bare outline.

Experiment 5.—The foregoing repeated, reflecting into the shadows a red colour in place of the blue. This seemed to have the effect of softening them down; but as the action, if any, was so slight, it is almost impossible to determine the exact effect.

Experiment 6.—The foregoing repeated, reflecting a yellow colour into the shadows, which appeared to have no effect whatever either in diminishing or increasing the shadows.

Experiment 7.—A piece of blue glass was placed inside the camera, midway between the lens and the dark slide, extending to each side and to the height of the centre of the lens. A photograph was then taken, which on development showed unmistakeably that the blue glass stopped certain of the chemical rays. It may perhaps be worthy of a remark, that instead of there being any decided mark across the plate (as I had anticipated), it was nicely blended together. This I think might be turned to good account; for, if we were to put a piece of glass upright instead of lengthwise against the side of the camera, we might soften down the side which receives too much light, and so tend to harmonise the picture.

Experiment 8, and the last of this series, is merely a piece of sensitised albumenised paper exposed to the action of the three primary with their complementary colours. Here, however, we find a difference in the action of colour in different photogenic substances, and it would be well to compare the results:—

	Albumenised paper.	Collodion.
Greatest action in the blue		Blue.
Second „ „	yellow	Purple.
Third „ „	purple	Green.
Fourth „ „	green	Yellow.
Fifth „ „	orange	Orange.
Sixth „ „	red	Red.

Of course the above table is only applicable to transmitted light.

In glancing over these experiments there are one or two points which deserve attention. The first which I would bring to your notice is the peculiar action of the red ray; for, while it stands last in the scale by transmission, it is little inferior to purple by reflection. Some operators have observed, in photographing flowers, that it sometimes occurs that a bright red flower will have as great

actinic force as a blue one. This I think may be put down as a photographic "unaccountable," if I may use the term—at least I think it is a matter that deserves investigation.

From experiments 3, 4, and 5, it will be seen that by reflecting into the shadows different colours we may either reduce or soften them; but in my opinion this may be very properly dispensed with, as, if the subject be placed in a good diffused light, the contrast of light and shade will be lessened; and although the exposure be somewhat increased, the results will amply compensate for the prolonged exposure. The finest specimens of photographic portraiture I have seen have been taken in dull weather. Most of the gentlemen of this Society will remember a portrait (being exhibited at one of our meetings in the last session) of an exceedingly pretty Irish lady. This, it was stated, was taken in a place entirely surrounded by houses and smoky chimneys; and I do think if more attention were paid to the proper diffusion of light and shade we should soon observe a considerable improvement in our photographic productions.

PRINTING AND TONING OF ALBUMENISED PRINTS.

By J. Stuart.

[Read at the Meeting of the City of Glasgow and West of Scotland Photographic Society, October 4, 1860.]

The question is often asked by those who are about to supply themselves with photographic mementoes of the living: "Are they permanent?" I have no doubt as to the permanency if proper precautions be taken to free them from the chemicals used in the fixing. I am sorry that so many think a few hours' washing will do for the freeing of the print from the hyposulphite. It has always been my opinion that mere soaking is not sufficient if they are intended to be permanent. To my mind a certain amount of friction is requisite to force a union between the water and the soda left in a newly-fixed print. Tepid water is an excellent substitute for pressure, as the soda dissolves much more rapidly in it than in cold water. I should not consider that prints floated in cold water would be at all permanent. It is the duty of all who are engaged in supplying the public with paper prints to do all in their power to make them permanent; if not, it will quickly tell upon themselves. The public will soon find out that they are not getting lasting mementoes, but "dissolving views."

I cannot say much about the old mode of toning and fixing, as I had little experience in it—I mean that of adding the gold to the soda, as recommended by Mr. Hardwich in his *Photographic Chemistry*. Till the introduction of a new mode I thought most of the *sel d'or* toning bath. The principal difficulty was to prevent the prints from running yellow. In other respects it gave very fine results. There was a richness of colour about them, and the half tones were well preserved. In consequence of the great care requisite in the washing when taken from the printing-frame, and my not being able always to attend to that matter personally, I was obliged to give it up. I have some prints toned by that method five years since, and they are as good as ever. The paper at that time was not so good as it is now—at least I did not find it so.

I have brought with me to-night a number of other prints done by the method which I am about to describe. I have selected them with a view of showing you what a variety of tones can be produced by it. To look at them one would hardly think them done by the same process. By no means do I lay them before you as specimens of our art, but merely for reference during the discussion which is to follow the reading of this paper.

For the printing, good paper is essential.—There is much bad paper in the market: it remains with you therefore to try and get the best. There is some good yet to be found. The plan I adopt is to try a number of samples till I get what I consider good, then secure as much as will keep me for some time. Having got good paper, the next thing is to get good prints, which is not such an easy matter as the procuring of good paper.

First, cut the paper to the size that will suit you best, so as not to force you to have an unnecessary quantity of silver solution on hand. For cutting the paper you should have a bone knife, kept clean, for the purpose. Handle the paper as little as you can. It provokes one very much to see a dirty fellow "paw" the paper all over; and then, if there should be any stains in a finished print, he is sure to blame the paper.

Secondly comes your silver bath.—Make it up to the strength of ninety grains to the ounce of water, adding one drop glacial acetic acid to every ounce of the solution. At first thought some may think this a great waste of silver; but that is not the case, which may be proved by the following experiment:—Take ten ounces of a ninety-grain silver solution; pour it into a tray; then take the gross weight. Having previously cut twenty-four sheets of albumenised paper 8¼ by 6½, take twelve of them, and float them just one minute each on the silver solution; preserve all the droppings, and add them to the tray. Now take the weight again, noting how much it has lost; then test for its strength: in this way you will find how much nitrate of silver you have lost. Next proceed in the same way, only take a sixty-grain solution, and float three minutes, which is the time generally allowed. I found, then, that it had cost me 10 per cent. more for nitrate of silver in the sixty-grain solution, and the prints were not so good. The first showed the image upon the surface of the paper, while the other looked as if seen through a veil. It is not enough that you should make the bath of the above strength, but that you should keep it up to it; testing it when you have ceased using it. Bear in mind, also, that albumen tends to neutralise the acid first added: but keep it always acid. By testing it with litmus paper you will soon discover, by the colour of the paper, when it has enough.

Pour now your silver solution into a flat dish, to about the depth of ⅜ths of an inch. There is a danger in working with too little in the tray, as it is apt to cause bronze lines across the print: a halt when laying the paper has something of a similar effect. When you have the silver solution in the tray you will find a dusty sort of scum all over it, which no amount of filtering will remove. The only way of getting rid of it is to take a slip of paper and pull it over the surface, having its ends pressed close to the sides of the tray: letting down the paper without thus cleaning the surface of the bath would cause the paper to have a marbled appearance on its surface.

All being now ready to lay the paper, take it in your hand by the end; let the other rest on the silver solution. Now lower it down as you would a plate on a flat (or horizontal) bath, having the light between you and the silver, so that you may see air bubbles. Let it lie only one minute; then raise it up at the end first down, so as to give it all the same time on the silver solution. Dry it in the dark room quickly by means of a stove, or as may suit you best. When dry, lay it in a drawer, so that it may absorb moisture again, and thus be brought to a uniform state. You will find it to lie better to the negative, and to give better tones in this damp state. It will be found a great advantage, if there is a lithographic press at hand, to give the sheets two or three pulls through: it will make the print much sharper, by giving the paper a finer surface. As to the keeping qualities of the paper just prepared, there is no fear of it for some time—I should say for about a week—if you keep it from the light and in a dry place. I have brought a canister with me to-night; there is paper in it prepared two months back. If some one would take and print upon a piece of it, it would satisfy them as to what can be done in that way. I would not advise you to prepare it purposely; but if it so happened that you could not get your prepared paper printed, it might suit your purpose well. It would be a great advantage to the photographer—and more so in the winter months—if he could keep the paper till the light would suit. I have never been successful in the keeping of paper that has been floated upon the silver for three minutes.

Having followed these instructions, and thus got your sensitised paper, you must look to your negative. If it is thin you had better turn it into the shade, as it will not print so well in sunshine, which has too powerful an effect upon the intense parts of your negative, causing the face to look flat and grey; but if, on the other hand, the negative is strong or dense, the best effect will be got in sunshine. In fact, to print with taste, you should have two kinds of paper prepared—one as rich in silver as possible, and another a slightly salted and silvered kind—using the strongly silvered kind for the thin negative, and *vice versâ*. I had almost said it was a shame, but it is a pity, that those who albumenise paper do not mark how much chloride it contains: till they do so, or we prepare it ourselves (which by the way is no great trouble), we must be in a state of uncertainty as to what we are doing.

There is some attention required to see that all the parts are printing equally. You will find in some negatives parts which come out too rapidly: others—as in the case of groups, some being in the foreground—get overdone, so as to make the impression on the paper destitute of light or shade. There should always exist a certain amount of difference between those in the foreground and those in the back, but not to the extent that at times is produced in the negative; of course, without that the picture will be flat and worthless. There is, as the Yankee would say who has been writing to one of the Journals

lately, a "little dodge which you may here practise." Take a large magnifying glass and hold it up to the sun, letting the focus (not the burning point) full on the face or faces, as the case may be. You can make the light large or small as you find it answer your purpose. The lens I use is about 10 inches diameter; and I have found it of great service to me when there was any thing white in the picture—such as a white dress, book, or letter—the details being visible when looking through the negative, but which would not print till all the rest of the picture was over-done. I don't lay down the use of the lens in this way as anything new: one cannot mention a thing that some one has not known before. I fear some of you may think I speak long about trifles. Your print is now ready for taking out of the printing-frame. In appearance it should be what you would say "just too dark." Some paper gives way much in the after toning and fixing; others little or nothing: practice can be your only guide. If you can be ready for toning in an hour or two, lay the print down on water (face downward) for about five minutes. This water should be kept till you have floated a number of prints on it; then throw it into a large jar kept for waste silver solutions. In the jar you may have some pieces of copper, which will reduce the nitrate to the metallic state. When you have a stock of it you may wash it and dissolve it in nitric acid; it will be quite good for the paper silver bath. Upon no account should the prints be *immersed* in the first washing water, as it would cause liability to stains, there being so much difficulty in removing the free nitrate out of the paper, and it throws down a quantity of the gold in the toning solution. After floating the proof on the first water, lift it up and plunge it into water kept constantly changing: a self-acting tray you will find a great advantage. Having turned them about three or four times in the hour or two they lie in the water, they are ready for toning.

Arrange now all your trays, side by side:—first your toning tray set inside another, so that you may pour warm water about the toning tray at pleasure; secondly, a tray with clean water; thirdly, the tray with the fixing solution. Toning solution:—chloride of gold in solution (one grain to the drachm of water) one drachm; water about two ounces; then drop in a piece of litmus paper, which at first will be reddened; then take a saturated solution of carbonate of soda, and add till the litmus is brought back to its blue colour—any more has a tendency to soften the prints. Throw it then into your toning tray. This is by far the best toning bath, as it it combines simplicity with certainty. The fixing bath is as follows:—hypo. of soda 6 oz.; water 20 oz. Pour in as much as will cover the prints you have to tone—more is not required. Do not use the fixing bath twice, as there is no certainty of getting well-fixed prints after it has been once used. I have often found them turn yellow: if not at the time after a day or two. It is so pleasant to see pure whites, one should not grumble to spend a few pence in securing them.

In toning the print lift it out of the water, and pop it into the toning-tray: keep it in constant motion with your left hand. When it is rather darker than you would like it to remain, lift it out with the left hand; give it a rinse through the water with the right hand, then through the fixing-bath, letting it lie for fifteen minutes, with occasional turning, so as to insure its being well fixed. If air bubbles get between the print and soda they will cause spots from imperfect fixing. Some may wonder how I say, take the left hand for toning and the right for fixing. Were you to knock the hand into the gold solution that had been in the hyposulphite of soda it would deposit all your gold. I believe that through this very small matter the manufacturer is blamed when the bath will not tone more than two or three prints when it should have toned six at least.

I now go on with the toning of the other prints, working with the solution first made, till it becomes rather slow; when by pouring hot water about it, it starts off again; and so on till the last of the gold is wrought up. The prints having been left in the hyposulphite of soda for fifteen minutes, put them into water kept constantly changed (as before stated in a self-acting tray). Having allowed them to have two or three changes of cold water, then turn on the hot—say about blood heat: keep them constantly moving about for twenty minutes or so. You may now turn off the hot and let in the cold water for an hour or two; then allow them to soak all night, when you may turn on the water for an hour or two again. Some recommend that the prints should be dried off between folds of blotting-paper: that I think unnecessary. Hang them then over a line to dry; when dry they are ready for mounting.

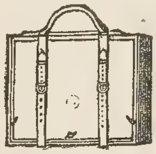
Though the mounting of the prints does not exactly come under this head, yet I may be allowed to say a few words on so important a subject. After the prints are dry the first thing is to cover them over with patent starch paste: they are then dried, trimmed on the edges, and are ready for mounting on cardboard. Having a lithographic press all ready, take a wet sponge and cover all over the cardboard. Lay the print you are to mount on the cardboard in its right place, holding the two together till you lay them face downwards on the stone: now put down the tympan, and one pull through will make them adhere, so that no amount of labour can take them off. In this way I can mount and press about 100 ($8\frac{1}{2}$ by $6\frac{1}{2}$) prints in one hour. There is another advantage in this mode—the boards do not turn up so much.

MEAGHER'S IMPROVED PORTABLE CAMERA.

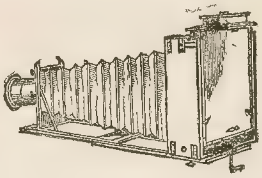
[Read by Mr. Simpson at the Meeting of the South London Photographic Society, October 18, 1860.]

This camera was, so far as the general design is concerned, I believe, invented originally by Mr. Kinnear; but the design in the one I am about to describe has undergone many modifications and improvements in detail. The chief claim I possess to bring it before the attention of this meeting is the fact that some of the improvements were suggested by myself to the maker. In stating this I do not claim any originality in the idea of these improvements, but merely their application in the present instance.

The points on which this camera claims the attention of photographers are portability, lightness, and efficiency, each of which I think it possesses in a maximum degree. The outside measurement of a camera for ten by eight plates is twelve and a-half inches by ten and a-half inches, and three inches deep: its weight does not exceed seven pounds, and, being supplied with a handle, it is portable in the highest degree. Its form when packed up is here shown:—



On opening the camera it is found to consist of a frame of Spanish mahogany or teak, three inches deep, having two grooves—the inner one to receive the focussing screen when packed, and the other to receive the dark slide or back. To the front is attached an extending body of leather, made with gussets like an accordeon or concertina, but having the form of an elongated truncated pyramid, which packs within the frame just mentioned. The base-board of the camera is made to form the front of the box when packed up. Within the base-board is a light but firm sliding-frame, by the extension of which the bellows are drawn out to their full extent. This extension is effected by means of a fine slow screw, which is worked at the back, thus affording facilities for the finest adjustment of focus from the back of the camera. Attached to the front of the sliding frame, to which I have just referred, is another hinged frame, which on being raised is found to possess grooves into which the part carrying the lens attached to the bellows is fitted, and being fixed by means of screws at any height possesses all the advantages of a sliding front. This small hinged frame is supported in position by oblique brass stays which are attached to the base-board, and, working on a centre, are laid flat when the camera is packed up. The frame constituting the body of the camera is attached to the base-board, either in a horizontal or vertical position, as the view to be taken may require, by means of two brass screws underneath. The form of the camera when erected for use is seen thus:—



I am now come to describe two or three important adjustments which the camera possesses, and which give it all the advantages of a double action swing back, both as regards lateral and vertical motion, without either the cumbersomeness or costliness usually pertaining to that adjunct. In the base-board, at the point at which the two brass screws attach it to the body of the camera,

are two curved slots, through either of which the screws attached to the body—which works on a brass pin in the centre—move for a given space, thus allowing the back, although fixed in the centre, to traverse the arc of a circle, and thus also gaining all the advantages of the swing back in that direction. The vertical movement is gained by a slight deflection of the lens, the frame which supports it working on its hinges, and is fixed in any required position by a screw which passes through a slot in the brass stays. I am aware that the use of this movement requires great care and some knowledge and experience, as, by moving the lever at the short end, a very slight inclination will cause a considerable deviation of the axis of the lens from its normal or true position. In the ordinary swing back the method of adjustment to give definition to objects in an advanced plane of the lower part of the foreground in a landscape, or of the figure in portraiture, it is customary to incline the top of the slide a little backwards, so as to adjust the distance between the objects in the foreground and that part of the plate on which they are delineated. Here it will be necessary that the camera itself shall be turned on its axis, or, in other words, that it be tilted, so as to give the back the requisite slope or inclination. In doing this, however, if the lens were rigidly fixed, it would no longer embrace the view to which it was originally pointed, probably little more than the tops of the trees and the sky being delineated. To remedy this, the facility of changing the position of the lens becomes of the utmost service; for, when the camera is thus tilted, a slight depression of the lens at once makes it include the desired view, and at the same time secures the direction of the axial pencils on the centre of the plane of delineation, whether it be the focussing screen or sensitive plate. Another point secured by this movement, which, to the artistic photographer, will be an important one, is the facility of slightly altering the direction of the axial pencils, and thus securing the best definition of an important part of the subject, irrespective of its occupying a central position, at the expense of some other part in which definition is of little importance. Thus, in a landscape, the foreground objects may often require, in order to produce the most artistic result, the best possible definition, which will be secured by directing the axis of the lens towards that part of the field, whilst the part which would suffer from this deviation of the axis of the lens would be the sky, in which definition is of little importance. I may mention here that Mr. Shadbolt, some time ago, devised a very ingenious method of effecting the very purpose secured in this camera by these simple movements. His plan was to attach the lens to a piece of wood constituting a section of a globe, which, being secured in the aperture, in front of the camera, possessed a ball and socket movement, allowing the lens to be turned in any direction. The especial object of this invention was an easy application, to ordinary rigid cameras, of this movement, which is here obtained, however, by a much simpler method. As I before remarked, it will be necessary, in making use of this adjustment, to use caution, remembering that, in proportion to the length of the lever, formed by the body of the camera, a slight movement of the lens will cause a very considerable deviation in the direction of its axis towards the plate.

It only remains to be added that single backs for wet plates, or double backs for dry plates, can be fitted to this camera without increasing its bulk; and further, to add that the material, mechanism, finish, and general workmanship, appear to be of first-class character throughout, thus securing the efficiency to which I first referred, as well as the portability and lightness which are so apparent as to need no further comment.

ON DRY COLLODION.

By M. A. Gaudin,

Calculator at the Bureau des Longitudes.

At the present moment the stereoscope has become the most important branch of photography. Notwithstanding the small dimensions of the proofs, I am fully convinced that in the execution of stereoscopic proofs, negatives as well as positives, the greatest quantity of chemical substances are consumed, and that they have given rise to a most important commerce.

If we do not employ albumenised plates for obtaining negatives, we operate upon collodion. But what a number of difficulties present themselves; for we require a laboratory at hand in order to sensitise the plates and to develop the images, without even taking into consideration that the degree of dryness of the air has a considerable influence upon the results.

It is therefore of the highest importance, for the prosperity of the stereoscope, to be able to operate upon dry collodion as we operate with albumen; and M. Vernier's letters have appeared just at the right time for the discussion of the question. Unfortunately, he promises to tell us why our experiments have been unsuccessful; but in this I only see a very ingenious mode of criticising what has been done or proposed, without ever sifting the question to the bottom, if we except his inquiring into the glutinous nature of the collodion, and his opinion that we ought to be able to modify it by certain additions, which he cannot indicate, having generally only very vague ideas on the whole question.

I will therefore again reiterate the facts. In what does albumen differ from the collodion? It differs from it in an essential point: it is soluble in water, whilst the collodion does not dissolve in it. It is true we render the albumen insoluble during the manipulations; but previously it was soluble, so that in iodising it the salt becomes thoroughly mixed with the albumen, and on passing to the silver *bath* the iodide of silver is produced through the entire substance of the film. At this moment the albumen is rendered insoluble. But the layer of albumen has already been transformed into an extremely delicate and spongy body, capable of absorbing in swelling all the aqueous compounds. It will suffice to look at the white of an egg which has become coagulated, either by heat or acids, to be convinced, from its opaline colour, that it is a very spongy body.

The collodion, on the contrary, is a fatty body—that is to say, soluble in a mixture of ether and alcohol, *which is precipitated by water*, and which has no affinity for it, but which unites with fatty bodies, and strongly adheres to them. This is the reason why, on collodion being poured on the plate, a division takes place when its solvent is evaporating: the collodion separates, and the iodide which has been added spreads above in the form of a film; and when this comes in contact with the silver bath, a continuous pellicle of iodide of silver is formed *on the surface of the collodion*, and not *in its interior*.

This we easily see when we make use of too weak a silver bath, or when we try to use a fresh bath of 2 or 3 per cent. only. The iodide of silver gets detached, and on the plate there remains a layer of limpid collodion.

Thus it is proved that coagulated albumen is permeated by watery liquids, whilst the collodion is impermeable to the same.

I will, however, give another convincing proof of it. For a long time I have had the idea of making use of a thoroughly sensitive collodion—that is to say, a collodion which contains iodide of silver. I at first found it very difficult to produce iodide of silver in the collodion without the latter becoming coagulated; nevertheless, I at last succeeded in the experiment, so that, having poured my collodion on the plate, I had, to all appearance, a layer of sensitised collodion, for it possessed its bluish tint to perfection. I thought I had nothing more to do but to expose, and then to develop with a solution containing nitrate of silver, for the impressing of the iodide by the light to be made apparent; and it certainly did take place throughout its substance, but the argental developer never produced aught but the slightest effect, however long the action of the light had been. The collodion is therefore, even when quite fresh, *impermeable to watery liquids:* its iodide is usually quite superficial, whilst the albumen, whether fresh or old, is *permeable to watery liquids*, and the iodide of silver is quite as much in its substance as on its surface.

Every preparation containing free nitrate of silver is subject to reactions, which will take place in time, even when protected from the light. We cannot preserve them for a long time without their getting weak. In order to preserve dry collodion as we preserve albumen, it must be subjected to washing, in the same manner as the albumen; and if we would only be, in this respect, as careful with the collodion as with the albumen, we should obtain the same good results, with this difference, that the sensitive layer, being wholly superficial and protected by nothing, is much more exposed to the influence of time.

If the collodion be well washed, it will, in my opinion, be preserved even better than albumen: for, at the moment of exciting, the nitrate of silver is introduced into the innermost part of the albumen; whilst, with regard to the collodion, it wets only the two sides of the film. I say the two sides, because it is quite evident that, during the immersion, the nitrate of silver comes instantaneously in contact with the surface of the glass itself. This can easily be observed whenever a badly-prepared glass contains organic matter at some place or other of its surface; for we always find there a production of silver reduced during the process of sensitising.

According to this we must, therefore, not only remove the surplus nitrate of silver on the surface, but also that which is towards

the side of the glass. In the albumen, the latter is by far less, because during its passage it comes everywhere in contact with iodide, by which it is decomposed.

In conclusion, I say, and repeat again, wash the collodion with the greatest care; immerse it in salt-water; and, lastly, wash it again with the distilled water, and you may confidently operate upon it in the same manner as you do upon the albumen.

STEREOGRAPHS.

Canterbury, Rochester, and the Watering Places on the South and South-east Coasts, by W. Russell Sedgefield.

(A. W. Bennett, Bishopsgate Street, London.)

The stereoscope is an instrument that, like the horseleech, continually cries, "Give! give!" and, according to the status of its proprietor, so must its food be. The geologist, mineralogist, botanist, conchologist, artist, &c., have each a class of slides which they most affect; nay, let a man's hobby be in almost any direction, it would be difficult to point out one in which food for his own particular stereoscope could not be found. It is a commercial axiom that "where there is a demand a supply is sure to follow;" but it is equally true that a supply not unfrequently creates a demand, which would perhaps scarcely have existed but for the pre-existence of the means of satisfying it.

It is of course easily enough seen that, in producing stereographs for those who have a pursuit, it is only necessary to depict subjects in which they take an interest, and the sale of them is already half accomplished; but what is to be done in order to catch the fancy of those who have *not* any special hobby—the οι πολλοι, the great mass of purchasers in expectation? Truly to do as Mr. Sedgefield has very recently been doing, in reproducing those haunts "where men and women most do congregate;" and the best of all possible times to bring them out is just the present time, when most of those who have been fortunate enough to get a short sea-side holiday have returned home, bringing with them a vivid remembrance of the scenes they have so lately visited. "Strike while the iron is hot" is an old proverb. Let the slides now before us come across the late sojourners in any of the localities depicted, while the scenes are fresh in the memory, and they are nearly sure to become possessors of them; and, having visited one place—Hastings for instance, and not Dover—a few of the latter must accompany the more familiar scenes just by way of contrast and for comparison.

In preparing a series to meet the requirements above indicated, there is scarcely that amount of room for artistic selection that would be satisfactory to such an operator as Mr. Sedgefield. It is not always the most health-restoring spots that abound in the picturesque; and the photographer must perforce take the places just as he finds them, or leave them alone altogether. There is no putting in a tree here, or leaving out a dead wall there, to improve the subjects; but they must be had in all their native beauty or ugliness, just as it may happen. It would, therefore, be unfair to criticise the series before us by the ordinary standards of artistic merit. But this quality has not been overlooked by the operator, for where the subject has admitted any choice the most has been made of it; and in all an endeavour is apparent to introduce as much of ART as NATURE would permit.

From Canterbury we have the Cathedral from the east, and also a well-executed illustration of Dean Lyall's Monument; but that which exhibits the best effect is No. 622, being a view of The Cloisters of St. Augustine's College, in which the *chiaroscura* is highly pleasing, although the subject is extremely simple. The patches of sunlight falling through the mullioned embrasures of the corridor upon the chequered floor, contrast admirably with the softened shadows, which, though deep, are beautifully transparent.

From Rochester we have the Cathedral, and from Rye the Shipyards. Each is full of incident, both in the distance and foreground.

A portion of the quay of Ramsgate Harbour, with some vessels alongside, may be taken as a sample of that resort; and a singular chasm in the cliff, through which the pier is seen in the distance, serves as a record of a Margate scene. It is evident from this last that Mr. Sedgefield employs a single lens camera; for three vessels out at sea, visible in both pictures of the pair, have slightly shifted their positions between the times of the two exposures—which is a pity, for they would greatly have added to the value of the effect had this not been the case.

Hastings is taken from the beach, on which a small brig and a dense crowd of fishing smacks are drawn up above high-water mark. The east cliff, with the pathway leading towards Fairlight Glen, are seen in the distance, and a gentleman is standing close to the water's edge.

Of Dover we have the Harbour, the Heights, and Barracks, Shakespeare's Cliff, with a portion of the railway along the sea shore; and on one of the cliffs near at hand a figure is very effectively posed, pointing out to sea.

The best of this locality is, however, that entitled the Bathing Machines, whether as regards execution, illustration, or composition. A crescent of houses, of the orthodox sea-side style, with the pleasant verandahs, form the back-ground; one *machine*, with its ugly canvas hood, is in the water, and another just drawn up on the ridge of shingles (*mem.* canvas hood considerably patched), while the rest are high and dry, almost on the shore. Midway is a "groyne," which as usual seems to have special attractions for the loiterers on the beach (we always notice three times as many people there as anywhere else); for here are ladies, gentlemen, and children, in various attitudes, intently observing the solitary machine or the towels spread out to dry. Close to the spectators is a group of little girls sitting on the beach with their wooden spades, while the transparent spray from the waves on the shore is beautifully given; and the wet portion of the shingle exposed to its influence contrasts well with the dry crispness of heaped-up water-worn pebbles under the blazing sunshine.

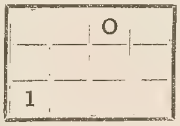
We have only to remark, in conclusion, that the whole are executed with Mr. Russell Sedgefield's usual skill.

Letters to a Photographic Friend.

No. VIII.

Dear Frank,

I have now to tell you of what came under my notice at the photographic apparatus *makers'* who have establishments out of the main thoroughfares of "this wonderful metropolis;" and the first that fell in my way was Routledge's, whose workshops, I may tell you, are situated at 14, John's Mews, Bedford Row, as he has moved from Devonshire Street, where in the first instance I bent my steps. Here I found he had in hand a general camera of large size, suited for the operating-room, with an arrangement for taking *twelve* "card portraits" on a single plate by means of one lens. This was effected by bringing twelve parts of the plate successively in front of the lens by a right-angled movement in two directions—

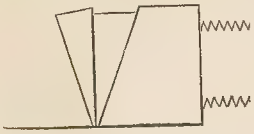


downward and sidewise—which you will comprehend by this tit-tat-to sort of diagram, the "first go" being at corner number 1. Four compartments are brought successively in front of the lens, and the frame is then pushed downwards in a groove. The row of four is then pushed before the lens in an opposite direction, and the plate frame then again pushed downwards. As Routledge lays himself out for "the trade," there was not much variety in stock for inspection, but what there was was of the right sort.

I then went off to Ottewill's, at Charlotte Terrace, Islington, one of our first camera-makers in more senses than one. Here a twin-lens camera was brought under my notice, with an arrangement for separating the lenses from 3 inches from centre to centre to a range of 4½ inches; but, to prevent light obtaining access to the plate, the separatable lens-carriers are attached to roller blinds, like the iron ones used for shop shutters—so that as the lenses are separated by means of double racks and a pinion, the apertures that would otherwise exist in the camera are covered over by the extension of the shutters simultaneously with the advance of "*the lens-carriers.*" This piece of apparatus is exquisitely made—in fact so neatly that it puzzles one like a conjuror's trick to know where the shutters go to, and is worthy of Robert Houdin. If George the Third was troubled to guess how the apple got into the dumpling, I guess he *never would have been* clear in his mind (if he ever had any; for, if one is to believe Thackeray, he was "out of that article") as to where the shutters went to, if he had had the opportunity of seeing this ingenious contrivance.

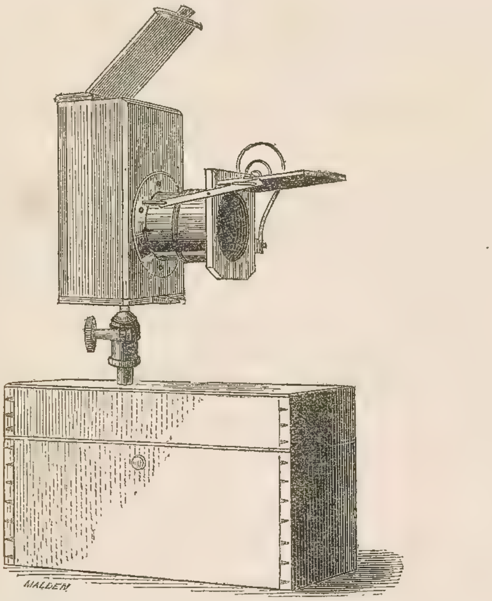
Another form of twin-lens camera consisted of a pair of bellows bodies placed behind each lens, so as to allow of a minimum or maximum range for lenses of long and short focus; such, for instance, as Dallmeyer has introduced in his new stereoscopic form. In this apparatus the fronts of the bellows are not fixed to the front of the camera; but they have a lateral motion

in grooves, so as to be able freely to follow the action of the separatable "lens-carriers." The wedge-shaped back of this camera has a swing motion in one direction, which renders this form of instrument very suitable for working with a pair of Ross's orthographic lenses, which, as I told you on a former occasion, are admirably adapted for taking stereographic portraits. The annexed diagram will give you an idea how the motion is effected.

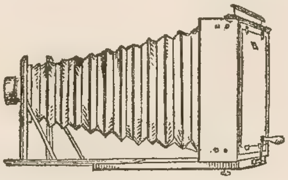


This camera has a range from $2\frac{1}{2}$-inches to $7\frac{1}{2}$-inches.

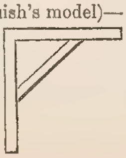
You will recollect that in a previous letter I called your attention to the small portraits produced by Skaife's Pistolgraph. Mr. Ottewill showed me a miniature camera that packed into a box $5\frac{1}{2}$ by $3\frac{1}{2}$ and $3\frac{1}{2}$-inches deep, with an instantaneous motion attached to the lens that some on theoretical notions will prefer to Mr. Skaife's shutters; but in either case, "the proof of the pudding is in the eating." Instead of being made in metal, it is made in mahogany, and a very pretty little thing it is. By aid of the following drawing you will understand the general arrangement of this



instrument. The shutter, you will see, is forced down over the aperture of the lens by means of a coiled spring, and is raised for the exposure by the leverage of an arm impinging on a pin projecing from the side of the shutter. As soon as the arm has been rotated past this pin, the spring forces the shutter down over the lens. As in Skaife's shutters, the exposure may be instantaneous or prolonged *at will*. Mr. Ottewill had likewise a very rigid



camera which, in principle, was like those I told you I saw at Melhuish's, Rouch's, and Shepherd's, but the conical body in this case was made bellows fashion, instead of in plush (as in Rouch's instrument), or waterproof (as in Shepherd's), and the frame-work and slides in wood, instead of in metal (as in Melhuish's model)—the telescopic base-board adjustable by an endless screw, being the same in each instance. By turning to my second and fifth letters you will see that I have described the mechanism of this form of camera. The rests for the glass in the plate-frame were in Ottewill's instrument castings in silver, in what might be called "gallows pattern." Thus:—

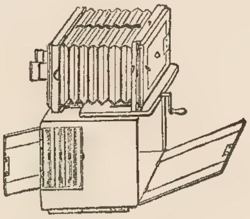


The camera examined was $12\frac{3}{4}$ by $10\frac{1}{2}$, and 3 inches deep, when packed, and had a range of 19 inches for focussing.

Curiously enough, on going to Hare's, at 140, Pentonville-road, I saw a camera constructed on the very same principle; but the board that carried the lens was hinged so as to have bearing when the struts were clamped, to give a still greater amount of rigidity to the bellows front. The camera I inspected was $10\frac{1}{2}$ by $8\frac{1}{2}$, and $3\frac{1}{2}$ inches deep, when shut up for travelling, with a focussing range of $15\frac{1}{2}$ inches. In both these instruments the range of focus obtained by means of the telescopic base-board was very considerable.

Thus, you will see that this form of camera is claimed by Ramsden, Rouch, Kinnear, and others, and, curiously, I myself can put in a claim for inventing this principle of construction as early as the commencement of the Russian war, when I designed a camera specially for war purposes to be used in the Crimea, portability being an essential element. The camera and "traps" were, in my case, carried on an axle to which a pair of large *folding* wheels were attached. The drawings were examined at the Society of Arts' rooms by Mr. P. Le Neve Foster, Mr. Fenton, and an officer of engineers, afterwards lost in his ship during the memorable storm off the Crimean coast. Instead of a telescopic base-board, I employed a coarse wormed endless screw, working in a tube, embedded in a piece of oak: the piece that carried the flange-plate of the lens worked to and fro on the screw, on the handle being turned. Being in one piece, this secured perfect rigidity in the base-board, which does not obtain in all forms of this model. Thus I am informed that an instrument on this principle was exhibited at the South London Society, the other night, which was *very* shaky in the base-board owing to that part being too lightly framed,* and from the lens-board being hinged to it on faulty principles. At that time I employed fine black cloth for the conical body, supported by five vulcanised india-rubber tubes; but the bellows cone is a great improvement on my primitive plan. In other respects my camera was the counterpart of these *novelties*.

I likewise examined, when at Mr. Hare's, a very compact twin-lens camera, and a peculiar arrangement for a swing-back which takes very little space; but you will find a description of both of these at page 188 in the present volume of THE BRITISH JOURNAL OF PHOTOGRAPHY. I, however, give you a sketch of the twin-lens camera.



I must not forget to draw your attention to Moginie's tent, which takes the fancy of many; but, as this is fully described and figured at page 177 of THE BRITISH JOURNAL OF PHOTOGRAPHY, I need not re-describe it to you. It may be obtained from the inventor, at 14, Albert Street, Camden Road, if you should think it suitable to your purposes.

I must now, my dear Frank, bring this letter to a close; and in my next will give you the results of my last look round London before I betake myself to my country fire-side.

So believe me,

Yours, faithfully,

SIMEON HEADSMAN.

Meetings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE first monthly meeting of this Society was held on Thursday evening, the 18th ult., at St. Peter's School Rooms, Walworth,—the Rev. F. F. Statham, President, in the chair.

The PRESIDENT, in opening the proceedings, observed upon the unpleasant summer they had experienced, which, in his opinion, must have been most unfavourable for photographic pursuits. If he might judge, however, by the large attendance that evening, the ardour of the Society's members was not to be damped by any amount of wet; and he

* See "Meagher's Improved Portable Camera," page 315 of the present number.

trusted that the gentlemen present had come prepared to produce specimens of their labours. Some advantages might have been derived from the moist state of the atmosphere, as effects might have been obtained which dry weather would not have shown. One gentleman, for instance, had just been showing him a very wonderful change in the appearance of a plate, which could not be accounted for, but which might have been caused by the continued wet. It had been announced at the last monthly meeting that the members of the Society would continue to meet during the summer months out of doors, but those meetings had been much interfered with by the weather. Three of those meetings, however, had been held, and he had witnessed the painstaking efforts of some of the members to obtain views under the very adverse circumstances in which they were placed. He would call upon Mr. Wall to read the report.

Mr. Wall, the Hon. Sec., then read the report, and the minutes of the last meeting.

The minutes and report having been adopted and confirmed,

The President announced a donation to the Society, by Mr. John Bailey, of Darlington, of a photograph of Professor Taylor and a group of figures, and by M. Joubert, through Mr. Simpson, of two other specimens. He also wished to say that the present meeting had been held in St. Peter's School-rooms to avoid the unnecessary expense the Society had been put to at their last meeting for the hire of a room.

Mr. Simpson wished to call the attention of the meeting to the specimens he produced of coloured photographs enamelled on glass, the invention of M. Joubert. They were printed in three colours, and fixed by burning.

The President asked if the invention was patented?

Mr. Simpson replied that it was. The process might be applied to all ceramic manufactures. It would lead to the ornamentation of many works of art which pass through the fire.

Votes of thanks were passed to Mr. Bailey and M. Joubert, for their kindness in sending the photographs and specimens.

Mr. Hughes then proceeded to read a paper *On the Mechanical Adaptation of Portrait Lenses for View Purposes*, and produced and explained the various arrangements therein described. [Mr. Hughes's paper will appear in our next number.]

The President, at the conclusion of the paper, moved that a vote of thanks be tendered to Mr. Hughes for his very able paper, and the great trouble he had taken to render so difficult a subject clear to those present. It was very desirable that the mechanical arrangements of photographic apparatus should be brought as near perfection as possible, as upon them depended, in a great measure, the delicacy of manipulation so necessary to the production of a good photograph. They were trying mechanical excellence in instruments of warfare, and he did not see why it should not also be applied to the peaceful arts. It was a decided advantage both with respect to economy and convenience, especially when at a distance from home, to have an arrangement whereby the same lenses and brasswork could be used for both purposes. He should have liked to have had a summing up from Mr. Hughes upon the respective merits of the different adaptations he had explained to them. Some of the contrivances were of the most complex character, whilst others—especially that suggested by Mr. Hughes himself—were evidently simple and cheap, and were apparently the best in all respects. However, he thought Mr. Hughes had thrown out that the more complex arrangements had excellencies peculiarly their own.

Mr. Ackland said he had various objections to make with regard to the arrangements produced. In the first place Shepherd's arrangement was no novelty, whereas that plan had been mentioned long before in the second, third, fourth, fifth, sixth, seventh, eighth, and ninth editions of Horne and Thornthwaite's *Guide to Photography*. Whatever advantage was obtained in convenience by using the same diaphragm was counterbalanced by the fact that no workman could mount a lens or turn the threads of the screws so that the axis of the lens when used one way should coincide with its axis when reversed. That was the case with nearly all of the arrangements produced. There was no fault in the workmanship—the fault was in the principle; and he was quite certain that accuracy could not be obtained by that method. Then he had another objection to make: when the lens was reversed there was the whole of the projection in front to reflect light into the camera, which produced a halo. This could not be avoided by blackening the projection. There was another objection to the arrangement: photographers as a body were amateurs, and if an apparatus were given them that they could do anything wrong with, they were sure to avail themselves of the chance. Now, in most of the arrangements there was nothing to prevent the lenses being screwed in with the wrong face of the lens to the object. He had had a camera returned from India as defective, and he found the only fault was that the purchaser had put the lens in the wrong way. Messrs. Horne and Thornthwaite burnished the front of the lenses' fittings in such a way that it was impossible to make a mistake in that respect, and he had also made a contrivance by which the lenses could not be screwed into the wrong place.

Mr. Hughes said that such a mistake could not occur with the Ross's arrangement he held in his hand; for, although the front lens could be placed in the position of the back one, there was no thread left exposed for the hood to screw on, so that if the lenses were wrongly placed the arrangement was self-detective.

Mr. Ackland said that certainly was an answer to his last objection. With reference to the use of the bayonet joint in Derogy's lenses, he did not consider that it would make the axis of the lens when reversed so true as the screw joint. Every lens ought to be mounted in the cell whilst the other portion of the brasswork was in the lathe, so as to cut the thread of the screw and the cell at the same time. The slightest thing would throw the axis out.

Mr. Eidmans said he believed that the landscape and portrait lenses ought to be separate instruments.

Mr. Ackland said he made them either way, but they were better separate. He sold the separate arrangements for the same price as the other form.

Mr. Blanchard asked whether the objection, that the rim of the reversed lens reflected light into the camera, applied equally to Millet's arrangement, which appeared to him extremely simple and good.

Mr. Ackland said the construction of Millet's arrangement did away with all reflected light, and was one of the best on the table.

Mr. Eidmans thought it would be very satisfactory if photographic societies had a room for experiments where the makers could send their various arrangements to be tested by competent persons.

Mr. Wall said that was a most excellent suggestion; but their funds would not permit of it, although he thought richer societies might follow it beneficially. They were, however, establishing an experimental committee for the express purpose of testing both mechanical and chemical apparatus used in photography.

Mr. Hughes said they were much obliged to Mr. Ackland for his critical remarks. In reply to an observation of the President, that he should have summed up the respective merits of the different arrangements, he begged to state that he wished to tell them everything he knew upon the subject, but he did not wish to express any opinion either in favour of, or adverse to, any of the arrangements which had been lent to him for this occasion by the various makers. It would have been ungracious in him to have borrowed an apparatus merely for the purpose of condemning it; and, in fact, he should not like in any case to give a decided opinion upon the subject, for what one person approved another did not like. One individual required a *multum in parvo*—something that would go into a thimble; whilst another liked to be surrounded with different arrangements, as he was then. The fact was that each of these various adaptations had its use, and had been manufactured to satisfy some craving want on the part of the customer. One manufacturer improved his apparatus by making it more complex, whilst another improved his by making it more simple. How one man, therefore, was to judge and to decide for all the rest he did not know. All he could say was that great ingenuity was displayed in them all. Before he sat down he wished to call Mr. Ackland's attention to one point. In his (Mr. Hughes's) arrangement, the front lens reversed was simply screwed in the place of the back one, and the usual portrait diaphragms did duty for landscape purposes, but had this peculiarity, that they were moveable, and could be adjusted forward or backward to suit the photographer's emergencies, whereas all other single lenses had their diaphragms fixed in one plane. Could Mr. Ackland explain why they were always so fixed?

Mr. Ackland said they fixed them because it was better to select a safe position for them than to let their customers place them at a wrong distance.

A Member asked Mr. Ackland how they could tell when the axis of a lens was central?

Mr. Ackland said that was a trade secret—one of the important secrets only known to a few.

The President said he did not wish to press Mr. Hughes into expressing an unfavourable opinion regarding any of the lenses before him, and he was sure the members present must be much obliged to him for his paper, and also to Mr. Ackland for his remarks upon the subject.

A vote of thanks to Mr. Hughes was then unanimously carried.

Mr. Simpson then read a "jotting" *On Meagher's Improved Portable Camera*. [See page 315.]

The President said that the chief advantage gained by the improvement, in addition to the general portability and lightness of the camera, appeared to be a movement whereby the field could be altered and more perfect definition obtained. Thus it would give more flexibility of application, if he might use such a term, than more rigid instruments would permit of.

A vote of thanks to Mr. Simpson for his communication was then carried unanimously.

The President announced a further donation to the Society, by Mr. Davies, of two photographs.

Mr. Wall said he was very much pleased to announce that the committee proposed for experimental purposes had been formed, and that at their future meetings they might hope to receive communications of value relative to its labours in testing or carrying out such processes, modifications, or suggestions as might arise from the proceedings of other societies, or that might transpire in any of the photographic periodicals. Mr. Hannaford had kindly consented to serve as secretary to the committee, which would be formed of the following members:—Messrs. G. W. Simpson, Sebastian Davis, W. Ackland, — Blanchard, J. Martin, C. Jabez Hughes, T. Clarke, — Borchert, G. J. Tear, and J. C. Leake. He trusted that at their next meeting they would have a "jotting" from the committee.

The PRESIDENT called the attention of the members to a plate exhibited by Mr. Howard, which was a most remarkable instance of the reversed action of light. It was a transmitted positive obtained direct in the camera.

Mr. HOWARD stated that the plate was prepared for the Fothergill process in the usual way, and after four minutes' exposure he found that instead of a negative he had produced a positive. He could not account for it.

Mr. DAVIES suggested that there might have been something peculiar in the chemicals.

Mr. HOWARD said the materials were the same as he had been in the habit of using. He had taken upwards of 400 or 500 plates, and had never met with such an accident before.

Mr. CLARKE then read a paper *On the Photogenic Action of Colour.* [See page 313.]

The PRESIDENT said Mr. Clarke was pursuing a very difficult course in endeavouring to produce coloured photographs. He was proceeding with different coloured lights, but in his (the President's) opinion that was not the right line to pursue. What was wanted was a surface capable of reflecting colour. In the wet process a coloured photograph was frequently observable on the film whilst wet, which disappeared on its becoming dry. In order to keep the colour, the same surface must be preserved, and this had not hitherto been accomplished. M. Daguerre had produced the colours in very great perfection, but that result had not been obtained since. The question was how to form a surface capable of absorbing and reflecting colour, and until this could be done it was in vain to hope for coloured photographs.

Mr. WALL said the experiments were of some value with relation to the proper lighting of the image. The obtaining of colour seemed to hold out such faint promise of success, that he almost regretted to find clever men devoting themselves to such a path. He thought, however, that the study of the actinic action of colour might be profitably pursued. It was one which had been much neglected, and which might be profitably investigated.

A vote of thanks to Mr. Clarke for his paper was carried.

It was then decided that the further discussion upon the subject should be postponed until the next meeting.

Mr. Hazelhurst, Mr. P. Meagher, and Mr. G. Triptree, were elected members.

Mr. WALL then announced that at the next meeting a paper would be read by Mr. Alfred Hervé, *On the Positive Collodion Process*, and Mr. Hannaford would read a very interesting "jotting" from the experimental committee.

The proceedings terminated with a vote of thanks to the President for his services in the chair.

IN future the South London Photographic Society will meet at half-past seven precisely, the chair to be taken at eight—it being found that much time has hitherto been lost in the examination of specimens and apparatus, and in conversations thereupon, the regular business of the evening being thus considerably delayed.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association was held on the 10th ult, at the Chorlton Town Hall,—Mr. William Griffiths, one of the Vice-Presidents, in the chair.

The HONORARY SECRETARY read the minutes of the last meeting, which were confirmed.

Three new members were then elected.

Mr. BARNBY called the attention of the meeting to the fading of two prints, purchased by him, and which were contributed about one year ago, by Mr. Draffin, to the Society. These were said by him (Mr. Draffin) to be permanent, although they had been only washed four or five minutes.

Mr. SHEARD said he had heard a gentleman describe the application of hot water for washing plates for the new process of Messrs. Petschler and Mann, when on a visit to a meeting of the Manchester Society. Not feeling satisfied with the use of a jug for that purpose, he had made a bath of copper, raised upon legs, so that, by the application of gas or a lamp, the water could be kept at the required temperature so long as it was needed. He begged to lay it before the meeting. He had tried a few plates by this process, but was sorry to say that they were not satisfactory; indeed, he might add, that he had not been perfectly successful with any of the dry processes. He brought with him a negative, veiled in fog, and wished to lay it before the meeting, and ask through the chairman if any member could inform him of the cause of his failure. He was convinced that one cause was the source of all his failures, as, whatever process he tried, he could not get a clear negative, but all were covered with fog like the one he then produced.

Mr HOOPER and several members stated their views of the cause of the fog being present, which was thought to be impure chemicals or imperfect manipulation.

Mr. SHEARD then proceeded to state that, with a view to prove the non-sensitiveness of a collodion plate coated with chlorided albumen, according to Messrs. Petschler and Mann's formula, he had undertaken a number of experiments, the results of which he would lay before the meeting. He had prepared a plate in strict accordance with their directions—that is to say, he had coated a plate with ordinary iodised collodion, sensitised it in a slightly acid bath, washed it thoroughly under a tap for five minutes, then, after slightly draining, had coated it with albumen and water, equal parts, containing chloride of sodium two grains to the ounce; he had then dried the plate by artificial heat, without exposing it to light. In this condition, the following day he exposed it fifteen minutes in a camera with a quarter-inch stop, six-inch focus landscape lens, and a medium light. After removal from the camera he poured over the plate the usual pyro. developer, mixed with nitrate of silver. Chloride of silver was produced, which was seen floating in white curdy particles in the developer, and after a time a faint impression was visible. He then washed the plate, but only fixed one-half of it in hypo. He had brought it with him for the inspection of the members. [The plate was then handed round. It was perceived that the portion which had been fixed appeared as a negative, whilst the unfixed part appeared as a transparent positive.] He had tried several others with like results. He thought that the alleged non-sensitiveness of these plates prior to the washing away of the chloride albumen was not proved.

A discussion on the chemistry of this process followed.

Mr. ARCHER handed round several negatives which he had taken by Mr. Whipple's albumen process. They had received a short exposure, viz., two minutes, with a six-inch landscape lens and three-eighths aperture; but he was occasionally subject to blistering of the film. With that exception, the process was simple and certain, and the manipulation easy.

Mr. ROGERSON showed a very large print, eighteen by twenty-two inches, representing a view in Wales, from a wax-paper negative, which was very much admired, the distance and half-tone being very well rendered. He also exhibited a stereoscopic camera, with four double slides, weighing altogether not more than two and a-half pounds, focussing-glass and all complete, exceedingly small and compact, which was considered to be well worthy the notice of all practising stereoscopic photography.

A vote of thanks to Mr. Sheard for his interesting experiments, and to Mr. Archer for his description of the albumen process, was passed. The meeting was then adjourned, after a vote of thanks to the chairman for presiding.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER VIII. *(Continued.)*

MATERIALS, &c.

I WOULD advise you to purchase these in the sets sold by our respectable dealers. I give Newman's colours the preference myself, as the more reliable and pure. A box fitted complete with all the necessary materials may be procured for a small sum, and this I think the better plan. You will require the magilp; colours; sable, hog-hair, and badger brushes, both flat and round; palette, palette-knife, a glass slab and muller; a small lancet, oils, varnishes, a brush-washer, and dipper. You will also need a mahl-stick. A rack drawing-desk, or small table easel, is best for small pictures; but for large an ordinary easel will be required.

Palettes.—The best palette for *our* purpose is a white japanned one, because then the colours and tints appear on the palette as they do upon the white surface of the paper. If you use a wooden one, it should be soaked with as much raw linseed oil as it will absorb, before use. For smaller pictures the palette is best fastened temporarily to the desk; for larger it is balanced on the hand by placing the thumb through an aperture for the purpose. It should be thin, light, and balance well. Keep the palette cleaned regularly after use, and never suffer the pigments to harden upon its surface. Two or three China tiles, a few inches square, will be of use for tints which it is desirable to keep clean and pure; as in working other colours on the palette some mixture may inadvertently be effected of serious consequence to the beauty of your colouring.

A Glass Muller and Slab.—A slab of ground glass, fitted into a wooden frame, and a muller, are wanted, to regrind the colours before applying them to your palette—a practice which I recommend you to adopt, as more delicacy and smoothness will naturally be looked for in pictures so small as photographs usually are than would be expected in larger ones on canvas.

Mahl-stick or Hand-rest.—This is used to steady the hand or arm in putting in minute work—the surface being in a wet state, not permitting the hand to touch it. For the smaller photographs, it is best to use a piece of wood, a few inches longer than the breadth of the picture, raised at either end by small blocks, which enable you to lay it over such parts of the picture as are not dry, by merely touching the desk on either side of it.

The Easel.—These are of various descriptions. The rack easel is the most convenient, and it is made large to stand alone, or small

for the table: instead of the latter, I use, and prefer, a rack drawing desk, to which I fasten my photographs with pins, and hang my palette on the same.

The Dipper is a small tin cup, made to fix upon the palette. I use two, one to contain oil, and one varnish.

The Palette Knife should be thin, tapering to the end, and there be most flexible. It should also be heavier at the handle than blade. Its use is to temper and rub down the colours before use, and sometimes, as I have shown, it may be used with effect for impasting.

Brushes.—All I have said on this subject for water colours might here be repeated. For photographic colouring in oil, such nicety of touch is required, and such care in manipulation, that the selection of really good brushes is one very important element of success. Brushes are of hog, sable, badger, fitch, and goat hair. All of these are of service to the artist, and I am fond, myself, of having by me as great a variety of brushes as I can secure. I cannot here describe all the purposes best served by various brushes, although such information would, doubtless, be very serviceable, but must merely add, that you may begin with a few red and brown sables, of the usual sizes, and a few hog-hair tools for backgrounds.

Sable Brushes should be chosen as already directed; and in painting such small work I prefer, as is generally done, those made more particularly for water-colour miniatures.

Hog-hair Tools are round and flat. They should be strongly made, and neatly finished. The ends should be of an equal length throughout, without having been cut to such; as in this case a coarse scratchy effect will be produced. You may test for this by the touch: if the ends feel flexible and soft, all is right.

Badger Tools are generally recommended, but few use them; a clean, soft ordinary brush answering the purpose better. A few long-haired camel-hair pencils will be useful for the purpose. The badger tool is sometimes known by the significant name of "softener," or "sweetener." If this tool be too frequently or incautiously used, the beginner will speedily lose the likeness, and produce an effect usually denounced under the term "woolliness."

The Brush Washer contains turpentine for rinsing and cleaning the brushes during or after work.

The Lancet is such as miniature painters generally use, and will be of service in removing any little lumps of colour, dust, or flue that may chance to make their very unpleasant appearance during progress—cleanliness, delicacy, and finish being essential for small pictures.

THE COLOURS.

Flake white,	Extract of vermilion,
Naples yellow,	Mars orange,
Yellow ochre,	Venetian red,
Roman ochre,	Madder lake,
Transparent gold ochre,	Crimson lake,
Roman ochre,	Madder purple,
Raw sienna,	Do. brown,
Brown sienna,	Indian red,
Cadmium yellow,	Rose madder,
Chrome yellow,	Scarlet lake,
Lemon yellow,	Ultramarine,
Indian yellow,	French ultramarine,
Gamboge,	Cobalt,
Italian pink,	Ultramarine ash,
Prussian blue,	Black lead,
Indigo,	Ivory black,
Terra verte,	Lamp black,
Green oxide of chromium,	Vandyke brown,
Emerald green,	Cappá brown,
Brown pink,	Bitumen,
Verona brown,	Raw umber,
Vermilion,	Burnt umber.

Remarks on these colours will be found in an earlier chapter, both in regard to their working, drying, and chemical qualities.

Oils, Varnishes, Magilps, &c.—The word "vehicle," already explained, would comprise all I now proceed to offer a few practical remarks upon. Great research and investigation have been recently devoted to this subject. Sir Humphrey Davy has done much in reference to the materials used by the ancients, and Sir Charles Eastlake has written learnedly and well upon the subject. For me, therefore, it must suffice if I confine myself to such articles as are more commonly used in absolute practice. W. B. Sarsfield Taylor's translation of M. Mérimée's work on the *Art of Painting in Oil*, published by Whittaker and Co., Ave Maria Lane, 1839, will be a most excellent work to procure.

Foreign Correspondence.

Paris, October 26, 1860.

THE French Photographic Society's opening meeting of this session, which was to have taken place on the 19th of October, and upon which I had counted for a host of novelties to be communicated to you, has been postponed because of the absence of the majority of the members. It certainly cannot be the beauty of the end of the season which keeps the photographers away from Paris, for October is as ill-humoured as any one of its elder brothers, the months of Spring or of Autumn, and it is much to be feared that the whole family from January to December will have the same character. Doubtless the absent artists may be found in storied cities, amidst agrestic scenes, or on the mountain slope, lingering to the last to catch the sunbeam which has so long refused to smile upon them. And yet I know some — and more than one — of these laborious travellers who are returning laden with a plentiful harvest. How they have managed I know not, but the results are there to prove my assertion. Thus, M. Braun (of Dornach) has just published a collection of stereoscopic views of the banks of the Rhine. This artist operates with collodion, and nearly always in full sunlight, which gives a very vigorous effect to his productions, and permits him to animate them with groups of persons, so that they become real little pictures; but this time he has been forced to content himself with that diffuse light which falls with uniformity upon the edifice or the landscape. His views certainly lose much by this, but they are not the less interesting. M. M. Bisson, Brothers, who had for this season the most marvellous projects—among others, that of setting up their operating-room on Mont Blanc—have been obliged to limit themselves to completing as far as possible their collection of glaciers, and to reproducing the most curious sites in the new French departments formed of Savoy. At the time that they intended to go and pitch their tent on the top of the giant of the Alps, several English tourists perished with their guides in a tempest, and that upon the very road that they would have been obliged to take. The event was not encouraging to amateurs of super-alpine portraits, so M.M. Bisson have had to postpone the execution of their photographic feat to a more auspicious year. Another of our great masters, M. Baldus, has also executed a series of views taken in Savoy, thinking that the recent annexation of that beautiful country, and the journey of the Emperor and Empress, would, in the eyes of the public, give an additional interest to those eminently picturesque sites. And lastly, M. Soulier, the associate of M. M. Ferrier (father and son), has returned within the last few days from his sojourn of several months in England and Scotland. He had obtained authority to penetrate into the different palaces of the Queen, and to take interior and exterior views of them. His mission would have been greatly facilitated by the kind orders which had preceded him in all royal dwellings, if the weather had not made a point of persecuting him. Imagine what must have been the disappointment of the poor photographer, and the obstacles he had to struggle against, when installed with arms and baggage in a gallery at the far end of a chapel, or in a spacious chamber, into which there penetrated but a feeble ray of light through murky air or falling shower! He had prepared his glasses before leaving Paris, not thinking he should be absent more than a month, and the same glasses served him till his return—a fact which constitutes the greatest eulogy of Taupenot's process that can be offered. In spite of all difficulties, M. Soulier has brought back a large number of stereoscopic *clichés*, which have perfectly succeeded. In addition to fifty views, offering the monography of Buckingham Palace — the royal residences at Windsor, Osborne, and Balmoral—a numerous series of views of London, of the Isle of Wight, of Windsor Park and its environs—he has given us a few subjects from old poetic Scotland. These, as well as all the others, are executed on glass. Among the latter are the ruins of Melrose Abbey, a panorama of Edinburgh, a corner of Loch Lomond, and, lastly, a ravishing view of Loch Katrine. Examined in the stereoscope, this little picture makes a vivid impression upon the mind of the spectator.

> One burnished sheet of living gold
> Loch Katrine lay beneath him rolled;
> In all her length far-winding lay,
> With promontory, creek, and bay,
> And islands that empurpled bright,
> Floated amid the livelier light;
> And mountains that like giants stand
> To sentinel enchanted land.

Nought is wanting but the mild face of Ellen Douglas, listening to the melancholy songs of Old Allen, or rowing to the shore to offer

the aid of her boat and the hospitality of her isle to the wanderer Fitz-James. But I find that I have let mere mention run into description. It is the fault of M. Soulier and his beautiful picture.

To conclude, I have just seen the specimen of a new publication which seems to me well imagined, and not less well executed. It is the *Galerie Contemporaine*, by Disderi, published with a text by Alphonse Karr, whom you must know as one of our wittiest writers, and one of those most savoured by the public. The work appears in numbers, each of which is composed of a photographic portrait, carefully printed upon China paper, and several pages of letterpress. All our celebrities will figure in this book. The price is moderate, and does not exceed that of ordinary illustrated publications.

As our photographers return, I shall have other new works to speak of, and, no doubt, some of the tourists will bring back new processes with them. Let us then wait and hope.

ERNEST LACAN.

New Books.

Notes on the Solar System.

By G. J. Symons.

(London: Stanford, Charing Cross.)

Mr. Symons, as a meteorologist, undertook to make photometric observations during the late solar eclipse, and has published the result arrived at, illustrating the same by means of a photographic proof, showing the gradual diminution and increase of actinic action during the passage of our satellite across the sun's disc. The following extract will explain the *modus operandi*:—

Photometric Register.

The following description of the mode of obtaining the photometric register (of which the accompanying photograph is a reduced copy) has been made rather more detailed than it would have been but for the possibility that some of the arrangements may afford useful hints for future occasions. The paper, after having been sensitised, was fastened on a table by drawing pins; over it was placed a double thickness of the stoutest brown paper, somewhat broader than, and double the length of, the sensitised paper: this opaque covering had an aperture in the middle (about five inches by half an inch); other coverings were then put over, and the whole left in a dark room till required. When taken into the sunshine everything was removed but the perforated cover, the aperture of which being brought over a portion of the sensitive paper, that part was of course exposed to the sun, and therefore it was darkened. At the expiration of five minutes (read off from a seconds watch in front of the observer) the covering was shifted by the breadth of the aperture, the first portion being thus covered and prevented from increasing its depth of tint, and a fresh part exposed by a movement equally easy, instantaneous, and effectual. At the conclusion of the observations the photograph was taken again into a dark room, removed from the table, and fixed in the usual manner.

Though the uniformity of the decrement of colouring was slightly disturbed by the occasional clouding of the sun, the gradual diminution and increase of actinic energy is probably as well shown as it is likely to be during a merely partial eclipse.

In addition to the photograph are tables and diagrams of curves, showing the variations of the thermometer, barometer, hygrometer, &c., as noted by other observers, whose names are quoted by the author.

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

DRY COLLODION.

To the Editor.

Sir,—As one of the Liverpool Photographic Club, I have felt some disappointment that no mention has been made in your pages (beyond the report of their proceedings) of the method so successfully revived by several of the members, viz., that of the Abbé Depratz, by introducing a small quantity of rosin into the collodion, and simply washing the plates very copiously, with the addition of invariably re-dipping into the bath just before developing, so as to restore the free nitrate temporarily removed, to ensure their keeping properties. *Vide* the last edition of Mr. Hardwich's work, page 375, and the aforesaid report, in No. 127 of your Journal.

I conclude you have not tried the plan, or we should have had a long eulogium from your able and impartial pen.

That you may be able to form some opinion upon it, I send you a proof taken from a negative so prepared. When I started, the atmosphere was very bright; but, of course, when I reached my destination it was clouded over. As the return train was to start shortly, and I wished to oblige an officer of the company, I had no choice but to expose the plate during so heavy a rain that was by this time falling that a friendly umbrella held over me hardly saved my bellows camera from being spoiled. The time was exactly three minutes, fourteen-inch focus, two and a quarter diameter of lens, and half-inch diaphragm. You may see the opening was large by the lines at the outer edges; but by what other method of dried plates will you obtain the definition of the foliage, as marked by the fir and the tree beside it, with the almost entire absence of actinic light? I think you will admit that the Manchester system of salting, with the further trouble of washing just before using (not always practicable), hardly comes up to this. This plate had been prepared a week before, and was snatched up at a minute's notice. Nor was my second shot inferior; for as my slide is double-barrelled, I could not resist banging away right and left—so bagging my other bird *malgrè* the pelting of the rain.

While on the subject I may mention, in answer to your querist, in the last number, who signs himself "Inquirer," that I was informed by the lady he speaks of that she always uses Fothergill's process *pur et simple.* Her only peculiarity of invariable success consists in most *plentiful washing*, which, she avers, is no "mere matter of opinion;" and that she never opens her camera unless the sun shines, and then the time is rarely less than six minutes—whereas, with rosin in the collodion, the same light would operate effectually in one minute. *Ecce signum!*

Should your readers be tempted with this statement, and, upon trying, find their film have a tendency to split up and peel off upon drying, however tough and firm it may have been at the first washing, let them, after clearing with cyanide, and gently but efficiently washing the plate and slightly draining, then flood over the plate a mixture of one part of albumen to two of water, and then set up to drain and dry: their gratifying specimen of labour saved, and process simplified, will adhere to the plate, I'll answer for it.—I am, yours, &c.,

October 19, 1860. C. COREY.

[We reserve our remarks upon the preceding till our next.—Ed.]

"THE OPTICAL GHOST."

To the Editor.

Sir,—Will you allow me to occupy a few lines in reply to Mr. Francis's letter on "The Optical Ghost?"

The fact of several persons having seen the mock sun, or whatever it may be, without the intervention of any lens, I think puts the ghost out of court; but, even were this not so, surely the figure would have been a misty crescent, and not a perfect disc, if it had been caused by any reflection in the lens. With respect to its only appearing when the darkness was greatest, such is not the fact, as it exists in No. 5, where the sun is more uncovered than in No. 1, and in this picture it is somewhat *darker* than the white cloud beside it; and it seems to me that any reflection from the lens or mounting must fall on the plate as an excess of light, and not less luminous than its surroundings. These and many other things about the image and its position induce me to believe it really was in the sky, and in some way connected with the eclipse. I may mention that a somewhat similar appearance was noticed and photographed, by Mr. T. R. Williams, during a former eclipse, on which occasion he was induced to photograph by first seeing the image. Several of his friends who were with him also observed it.—I am, yours, &c.,

Middlesex Hospital, Oct. 25, 1860. CHARLES HEISCH.

PHOTOGRAPHY ON WOOD.

To the Editor.

Sir,—Can you, or any of your numerous readers, inform me if there have been any patents granted for the production of photographs on wood taken *directly in the camera*, and which will admit of the insertion of the engraver's tools without the *chipping off* of the surface of the prepared block, thereby rendering the photograph useless as a guide to the engraver?

I am aware that patents have been granted relating to the "printing of photographs on wood" for engraving purposes, and which produce a *reversed impression* of the subject when engraved and printed from the wood block.

My reason for thus troubling you is, that having perfected a process for producing photographs on wood *directly in the camera*, I wish to ascertain if anyone has produced similar results before me, as I should be very sorry were I to make my discovery known, and some one to immediately claim the priority of the invention, which, you are aware, has often been the case lately respecting processes in the photographic journals.

Some five or six years ago I tried many experiments to obtain photographs directly on wood, so as to be reversed as in the manner of all drawings on wood, and in each experiment succeeded, so far as regards the perfectness of the photographic image; but, upon my attempt to engrave the subjects, I was annoyed at finding, upon each insertion of the graver, a piece of the photograph chip off, consequently preventing my proceeding any further.

The chipping was caused by the prepared surface being too thick; and, at the time, if I made the surface thinner, the nitrate of silver would enter the pores of the wood, and stain it, which was another great drawback, as the engraver would then, in a great measure, be unable to see the nature of the engraving as to the *fineness* or *coarseness* of his work.

However, I can now obtain them to my satisfaction, as the photograph is as perfect in detail, &c., as a positive on glass—the surface does not chip off, the wood is not stained, neither is its nature altered in the slightest; and the engraver will find no more difficulty in engraving than on an ordinary drawing on wood.—I am, yours, &c.,

Birmingham, Oct. 24, 1860. JUSTITIA.

FADING NEGATIVES.

To the Editor.

Sir,—I am much annoyed at the fate of most of my old negatives, and shall be exceedingly obliged if you or any of your readers can suggest a remedy. After a time, more or less, they begin to show spots and stains, commencing generally from the edges of the glass, and gradually extending over the whole picture, completely spoiling it. The stains, however, sometimes appear in patches unconnected with the edges. Whatever care I take the result is the same; and negatives taken only a few months ago are beginning to suffer in the same manner. My own impression is that it is due to damp, as the other surface of the glass is always moist from that cause, even speedily after being dried at the fire, from, I suppose, its hygrometric nature. I use the best plates, obtained at Thomas's, and his chemicals. Perhaps you will also kindly answer the following queries, which may have a bearing on the above point:—

1. Which is the best mode of fixing with hypo.?—placing the plate on a levelling stand, or immersing it in a solution of hypo.?
2. Is it best to remove a small portion of the collodion film all round the edges, after fixing, so that the varnish may extend beyond the film?
3. What varnish is the best for negatives? I use the amber and chloroform, being so very convenient of application.
4. How can the hygrometric tendencies of the glass be obviated?
5. What boxes are the best for storing away negatives? I find the above results happen equally in metal, deal, and mahogany.

I am sorry to be so troublesome, but I fancy there must be some other means of obviating this destructive tendency, and I am sure you will help me.—I am, yours, &c., MEDICUS.

Bristol, October 26, 1860.

[It is possible that your negatives may have been imperfectly cleared of the hyposulphite of soda, or that they may have been varnished before the film was thoroughly dried: in either case the fault would cause the defect. Glass made with a superabundance of alkali would be hygrometric—a condition which would bring about the same result. For this there is no remedy but that of using a different sample of glass. Negatives should on no account be kept in a damp situation. Whatever be the primary cause, decomposition of the pyroxyline by moisture in contact with it is the immediate cause of your annoyance. In reply to your queries:—1. Immaterial, but immersion is more likely to disturb the film.—2. We think it is. Without doubt it adds neatness, and is somewhat of a precaution against damage to the edge of the film.—3. Soëhnée's, sold by Gaudin and others. Amber and chloroform, when good, is very good; but the quality is very uncertain. The only objection to Soëhnée's is that it requires heat in application.—4. Impossible to remedy it, if existing.—5. We prefer those made of tin: next to them mahogany.—Ed.]

RECOVERY OF SILVER FROM OLD BATHS.

To the Editor.

Sir,—Would you have the kindness to inform me, in your valuable Journal, how I could get pure nitrate of silver from my old baths? I have several pints, but they are too acid, or something of the sort, so that I cannot work with them. If I have to evaporate, would you inform me how?—I am, yours, &c.,

A YOUNG PHOTOGRAPHER.

[Add to each pint of bath half an ounce of common table salt dissolved in an ounce of water; and when the white and clotted chloride has settled, collect it on a cloth, and let it drain and dry in a warm place. The operative chemist will give you pure nitrate of silver in exchange for it; or it may, if you prefer it, be run down into a button of silver, by mixing it with four times its weight of carbonate of potash and carbonate of soda, equal parts, and projecting the mixture, a little at a time, into a Cornish crucible heated strongly at a blacksmith's forge. All the materials must be quite dry.—Ed.]

RECLAMATION.

To the Editor.

Sir,—In The British Journal of Photography I see your correspondent, "Simeon Headsman," describes a tourist's camera brought out by Messrs. Burfield and Rouch, of the Strand, London: at the same time he mentions one of similar construction he saw at Messrs. Shepherd and Co's., Farringdon Street. I do not think the camera worth being styled an invention; but any merit due to the designer of it I certainly lay claim to. I did not (as he says) furnish Mr. Eidmans with the design, but with an old camera which has been in use the last seven years. There is one peculiarity in the camera he does not mention: the lens is 1½ inches diameter, taking pictures 8½ by 10½ inches, the definition of which is not surpassed by any lens in the market, be it orthoscopic, orthographic, or any other with a new name. This camera was exhibited at a meeting of the London Photographic Society four or five years ago (the year Mr. Fenton was in Yorkshire), along with views in North Wales, taken with it; but, when I mentioned the smallness of the lens, the thing was ridiculed, and myself looked upon as one trying to dupe the Society.

I should not have written to you on this subject at all but that in your number for this day I see that Messrs. Horne and Thornthwaite have copied my design for a tripod, which was sold to the public along with the tourists' camera. Mr. Bland, of Fleet Street, was shown one of these tripods, and I believe purchased one at the time. If further proof be necessary I will at any time refer you to the optician who made the tripod for me, and also to parties who purchased them. In conclusion, I think it would be but honest if dealers manufacturing articles already in the market would give a little of the honour, if none of the profit, to the designer.—I am, yours, &c., J. W. RAMSDEN.

Leeds, Oct. 15*th*, 1860.

[Our correspondent does not seem to perceive that there is no difficulty in taking a large picture with a small lens; but the difficulty consists in taking a large *angle* of picture with a small lens.—Ed.]

AUTOMATIC WASHING-TROUGH.

To the Editor.

Sir,—Since the first introduction of Taupenot's process I have been in the habit of using a washing-trough, modified in form, but on the same principle as that described and figured by "H.," at page 299 of your current volume. I have found it all that could be desired for washing plates under personal superintendence; but, with an eduction siphon of a capacity much larger than the feed-pipe, it cannot be trusted to as self-acting, and it is not therefore to be depended on for the washing of prints to be left to themselves for a prolonged period. A siphon of four times the capacity of the feed-pipe, as spoken of by "H.," cannot *fill* except with help or by accident, and cannot therefore empty the trough automatically. Such a siphon, if of the common form and under ordinary circumstances, can only be depended on as an overflow pipe, the trough remaining full to some part of the level of the siphon's bend. "H.," or some other correspondent, can, perhaps, suggest a means of overcoming this difficulty. If overcome, I cannot imagine a less troublesome or more effectual system of thorough washing.

What occurs to me as a *simple* plan is the constriction of the siphon tube at some point on the exit side of the bend, the object being to secure, if possible, the filling of the tube in the first place, with the least amount of friction afterwards, when the action of the siphon has commenced.—I am, yours, &c., WM. CHURCH, Jun.

[Possibly the addition of a valve to the bottom of the long leg of the siphon, formed by a disc of metal, covered with india-rubber, and arranged somewhat after the fashion of a beam balance, might do. It should be weighted on the opposite end of the lever, so as to press the disc up against the bottom of the tube, and the weight should be sufficient to retain a column of water within one inch or two as long as the tube.—Ed.]

ALBUMENISING, &c.

To the Editor.

Sir,—I have no teacher but that which your valuable Journal affords. I have commenced taking negatives, and I do not succeed at all well. Enclosed is a specimen of one of my attempts, and I should feel much obliged if you would point out its defects in your next number, in order that I may endeavour to improve. The negative of the print sent was taken by a single lens, and treated with bichloride of mercury, and afterwards with a solution of iodide of potassium poured over it.

I have at command any quantity of fresh eggs, and feel very much inclined to albumenise my own paper. Will you have the kindness to give me a good formula, and say also whether the paper is salted just before floating upon the albumen? Is the formula given in answer to "No Chemist," in your last number, for dry plates? or for albumen for paper? By answering the above questions in your next Journal, you will greatly oblige.—I am, yours, &c., OLD MUFF.

[We can by no means acquiesce in the correctness of the signature adopted. The specimen received, though not anything like perfect, is far better than many that we see which are regarded by the producers as successful efforts.

Your negative is *under-exposed;* the lights and shadows present too marked a contrast—half-tone being deficient. With a proper collodion there is not the slightest need to use the bichloride of mercury to intensify, but a sufficient density can be obtained at once by the first development. The collodion you have employed is most likely *too thin;* add more pyroxyline to it, or get another sample to wash with.

In albumenising paper you do *not* salt it first—the object being to keep the image on the surface of the paper as much as possible. You should add from fifteen to twenty grains of chloride of ammonium to each ounce of albumen; or, what is better, dissolve the salt in a small quantity of water, and add it before beating it into a froth, which may be done by several convenient methods—for instance, by shaking it up in a large wide-mouthed bottle; by beating with a bunch of quills; or, easier than either, by the apparatus of Mr. Noton, figured in a former number. The frothed albumen will all have returned to the liquid state in about forty-eight hours, when, after filtration, it is fit for use.—The formula mentioned was for dry plates.—Ed.]

METALLIC SPOTS ON ALBUMENISED PAPER.

To the EDITOR.

SIR,—So much complaint continues to be made by the consumers of albumenised paper, on account of the innumerable metallic spots upon the surface, that any means by which this great annoyance can be prevented, or at least mitigated, should be used.

With regard to the cause of these spots, many attribute them to being in the pulp of the paper in its manufacture. This may be to a certain extent probable, but, from experience, I have proved the great cause is in the rolling of the albumenised surface,—the public generally looking so much after a beautiful surface, to obtain which, in the rolling, great pressure must be used: thus the particles of metal which, by friction, are broken off the cylinders are firmly embedded in the paper. If the manufacturers of albumenised paper were to carefully dry and press it well, and in that state supply the public, this great vexation, I am certain, would be overcome; and, when the fine and glossy surface is required, that can be obtained by afterwards having the pictures rolled when mounted and finished. This plan would be appreciated by the photographic houses, who are too frequently blamed for faults in paper over which they have no knowledge or control.—I am, yours, &c.,

October, 1860. J. S. EIDMANS.

[It will be noticed that the assertion made in the above letter, relative to the source of the metallic spots, agrees with the views expressed by Mr. C. Jabez Hughes, in his paper on the subject.—ED.]

ENCOURAGEMENT OF ART.

To the EDITOR.

SIR,—If you have not yet seen the annexed advertisement, it must surely be owing to the innate *modesty* and *forbearance* of the principals at South Kensington, whose well-known consideration for trade interest (*vide* a big blue book) naturally prevents them from attempting to damage legitimate speculation.—I am, yours, &c., QUASHED.

[ADVERTISEMENT.]

GRAND NEWS! GLORIOUS NEWS!!

Works of Art at less than a tithe of their value!!!

MESSRS. Carbon, Greentomb, and Co., having been assisted with almost unlimited means by that well-known capitalist, Mr. John Bull, have, with an *entire disregard to expense*, fitted up an establishment for pursuing the art of photography at the classical locality well known as the BROMPTON BOILERS, where they have determined to supply the public with photographs of WORKS OF ART at prices that will *defy competition*.

Indeed, far from taking into consideration such a low view of the subject as that of profit, the charges have been fixed at a rate so moderate that the articles may with truth be said to be

ALMOST GIVEN AWAY!

N.B.—A branch at Great Russell Street, Bloomsbury.

INTRODUCTION OF PHOTOGRAPHY AS A BUSINESS.

To the EDITOR.

SIR,—I have waited for the appearance of three numbers of THE BRITISH JOURNAL OF PHOTOGRAPHY, to see if some patriotic individual more able than myself would take up the cudgels against your American correspondent, Mr. Seely. But, as no one else seems inclined to show fight, I cannot let another opportunity pass without attempting the defence of British photographers.

The paragraph in Mr. Seely's letter that I more particularly wish to notice is the one beginning with the startling piece of news that "photography was first made a business in New York, and they were New Yorkers that inaugurated the business in London." I really owe Mr. Seely my best thanks for enlightening me on this subject; for I suppose I must have, during the last twenty years, been labouring under a series of false impressions of a most absurd nature. I had always thought that Messrs. Claudet and Beard were the introducers of the daguerreotype into England, but it seems it is not so. I had also fancied, most stupidly, that the daguerreotype was first made a business in *Paris*, but I suppose I was wrong. How much I have been in error too about photography proper! I had always fancied that Messrs. Henneman and Malone, Cundall, Hennah, Laroche, and Fenton were the first "inaugurators" of photography in London; but in that I am also mistaken—or are these gentlemen just named all New Yorkers in disguise?

But a truce to joking, for the next paragraph contains a serious insinuation:—

"We have no Daguerre, Talbot, Archer, or Hardwich here, but we have men who can put their ideas into action." (!)

Now, if I understand the English language rightly, this means that these great men are nothing but idle visionaries, putting forth ideas that other men, New Yorkers no doubt, put into practice. We all of us know what Talbot and poor Archer have done for photography, and we have daily proofs of what Mr. Hardwich is now doing for it—nowhere better, perhaps, than in the articles from his pen that appear in THE BRITISH JOURNAL OF PHOTOGRAPHY. Will Mr. Seely produce a book, I care not by whom, in which there are more "ideas put into practice" than in the last edition of this author's work?

I call on Mr. Seely, as an American gentleman and an honourable man, to withdraw so obnoxious an insinuation, and to do justice to both living and dead by apologising for this unfortunate paragraph. I cannot fancy that Mr. Seely could have written it deliberately; and I feel sure that although his letter, as he acknowledges, has a tone somewhat *apologetic* and *boastful*, it is *not*, as he afterwards says, "a fair expression of American sentiment on such subjects."

I have said nothing in defence of M. Daguerre, his talented and courteous countryman, M. Lacan, can do it better than I can.

MRS. SPRIGGINS'S "TWO-PAIR-BACK."

P.S.—Mrs. S. would have written herself but is laid up with the spasms, having been dreadfully *worritted* by the goings on at the Brompton Boilers.—M.S."T.P.B."

ANSWERS TO CORRESPONDENTS.

QUERIST (Leeds).—An achromatic meniscus.

F. N. D.—Apply to Messrs. Frith and Hayward, Reigate.

SECUNDEM ARTEM.—A very small one is of no use for the purpose.

THOMAS J.—Maxwell Lyte's toning bath. Hollingworth's third paper.

EUGENE.—Cyanide of potassium, because it injures the lights less than the other.

G. M. R.—We have no notion of doing anything of the kind. If he wants an opinion let him seek it in the usual way.

R. M.—You can cut the india-rubber with a pair of scissors with readiness if you immerse it in water during the operation.

The answer to your second query will be found by referring to the letter of "A Young Photographer" in the present number.

S. MOSELY.—A gutta-percha tray will do very well for what you require. If you have any doubt about its cleanliness, use a few drops of dilute nitric acid.

STARTLING FACT.—We have no faith in the writer you mention: a very little astonishes him. He is a bit of a wondermonger, if we may coin a word for his benefit.

INTERIOR.—We think that, for your present purpose, you had better adopt our own honey process, or else Mr. Sedgefield's plan of washing in distilled water before exposure.

DREADFUL MUFF.—Procure a pneumatic holder and your difficulty will at once disappear. It is wonderful that any one manipulates without these very convenient tools, seeing that their cost is but trifling.

J. R.—Read the "Letters to a Photographic Friend," recently published in this Journal, and you will find a description of several operating tents, boxes, &c. You will then easily be able to select that which suits you best.

SPOTTY.—Your dilemma is one easily got out of: you have simply forgotten to saturate your nitrate bath with iodide of silver. Coat a plate, and immerse it, leaving it in all night, and you will most likely find that the bath will work properly next day.

F. SCOTT.—Mr. Francis Bedford took many of the same Welsh scenes that were previously exhibited by Mr. Fenton—the former adopting a more manageable size, viz., about ten inches by eight inches, though those appear to be somewhat larger than you ask for.

AGATHA.—We should not hesitate for an instant as to which of the two to select—that at £35, decidedly. There is no comparison between the two. However, we never recommend large lenses to amateurs; they are never so satisfactory in performance as smaller ones.

CALOTYPE.—We do not think that you will do any good in taking stereographs by any modification of that process. Perhaps the turpentine waxed-paper process, introduced by the Rev. Mr. Sisson, may answer your purpose if you will not use glass. A pamphlet on the subject was published some time since by Messrs. Marion and Co., Regent Street, London.

KELVEDON.—If you will turn to our number for the 1st October, in the present year, you will find an article extracted from the *American Journal of Photography*, which article was read before the American Society, and contains all that has been published on the subject. We must, however, add that, in our opinion, the writer has probably given fancy the rein, and it has rather run away with him.

J. H. SLATER.—If you use black varnish to stop out a sky, it should be applied to the back of the glass; partly in order to avoid injury to the negative, and partly to soften the otherwise hard outline. We believe, however, that the best plan is to print a proof, and then, *without fixing it*, cut out the sky very neatly; then expose the sky part to the light to blacken and fix it in the ordinary way. It may then be carefully attached to the sky of the negative.

G. F. W.—The foot in the tripod was hinged at the bottom as you have found out: it was an omission on our part not to have stated as much. If for dry plates you would find Hare's suit you. The fifth on your list is very good; but we suspect that the cost will not be less than that which you say frightens you. If you work wet plates in the field you might readily make your own camera, using no dark slide at all. We shall probably have something to say about the process indicated in our next. We have heard nothing at all of our correspondent since the abrupt close of the last letter we published.

SCEPTIC.—The light you mention *is* adapted to portraiture. The specimens are *not* equal to those taken by ordinary daylight, nor is it possible that any mode of artificial illumination can *equal* daylight, because the shadows can never be quite the same, as you will readily perceive by looking at any person—first by the side of a window, and secondly with a lamp or candle on one side of him; in one case the rays of light reach him in parallel lines, in the other by diverging ones. Still, the instrument is very useful, and, when judiciously applied, gives very good results. Your note reached us too late for reply in our last.

A NOVICE, R. T. D.—Thanks for the specimens. You cannot materially quicken old collodion; if too highly coloured, some benefit may arise from immersing a slip of pure silver or cadmium in it, to remove the excess of free iodine. We do not think you need any other book than Hardwich's: the fault of which you complain may be due to the *albumen*, which, in the process you employ, should be carefully filtered, after having been frothed, as it is not washed off as in the Fothergill process. Gallic or pyrogallic acid is better for this process than an iron developer as a rule. There is no need to lose faith in dry processes: the error is solely in the manipulation somewhere.

J. R. A.—The specimen labelled "blisters" is so crumpled that we cannot rightly judge of the cause of their appearance: it is not improbable that they are due to too great pressure in obtaining an artificial gloss on the paper. The reddish granular appearance on the card portrait is evidently due to the paper having been prepared with albumen in an improper state, probably that which has not been sufficiently frothed, and containing portions of different density. On careful examination, the reddish marks are seen to assume a tolerably regular *rippled* appearance. If the albumen used be properly prepared, then it is owing to some fault in the drying: one of the two we are certain it must be—that is, either the albumen or the albumenising operation. Your third specimen is an unmistakeable case of "measles" in a mild form. Disderi's lens is one of four inches (from back lens) focus, not diameter. Of course pyrogallic acid is added. Negatives are best kept in a racked box; but, if you want to store a large number at little cost, you can do so by gumming a thick piece of card at the back of each angle, which will keep the plate from touching the next on which it is laid.

*** Mr. Hughes's paper, *On the Mechanical Adaptation of Portrait Lenses for View Purposes*, with many others, is deferred till our next number.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 130, Vol. VII.—NOVEMBER 15, 1860.

Those learned in mythological lore assert that even Jupiter occasionally nodded; it is not to be wondered at, therefore, that a mere editor should sometimes be "caught napping." At the meeting of the Manchester Photographic Society, held on the 3rd ult., a paper *On a Modification of the Collodio-Albumen Process* was read by Mr. John Parry, which may be found at p. 298 of the current volume. We have been informed, by the courtesy of the editor of a contemporary, that Dr. Ryley feels aggrieved at our having inserted that paper without drawing attention to the fact that the method of operating therein proposed was introduced by him nearly a year and a-half ago, and that the *principle* involved was advanced so long back as the 15th July, 1858, in a letter from him which we published in our issue for that date. We never voluntarily abstain from giving due credit to those who have introduced any useful suggestion; and on the present occasion our having omitted it arose from inadvertence. When we perused the proof of Mr. Parry's article the remembrance of Dr. Ryley's previous experiments naturally occurred to our mind, and we intended noticing the fact; but we were just then deeply engaged upon the examination of the South Kensington iniquity—a subject of such absorbing interest that, like Aaron's rod, it swallowed up all the rest; and we must frankly admit that our indignation on that score fairly obliterated for the moment any recollection of this matter.

At the two meetings of the North London Photographic Association, held in April and May, 1859 (reports of which appeared in vol. 6, pp. 110 and 137, of this Journal), Dr. Ryley explained, and exhibited specimens produced by, the method of operation erroneously supposed by Mr. Parry to be new, and which he will perceive, on reference to the number for the 1st May, 1859, p. 110, was described by Dr. Ryley in almost the identical words employed by Mr. Parry in his paper. As regards the theory propounded, we are by no means prepared to accept as proved that which has been advanced by these gentlemen; but certainly the use of hot water appears to be capable of advantageous application, whether for the purpose of coagulating the albumen or otherwise. So, without being too nice about the cause of its utility, let us accord thanks to Dr. Ryley for introducing it, and to Mr. Parry for drawing attention to it anew.

At the last meeting of the South London Photographic Society, a paper *On the Photogenic Action of Colour* was read by Mr. S. Clarke (see p. 313); a subject which, we are convinced, would well repay a systematic investigation. Our object in referring to this paper at present, however, is to draw the attention of its author to certain considerations which appear to have escaped him, and to some little omission of particulars from his article. With reference to the omission to which we allude, he says, in describing experiment 8, that it "is merely a piece of sensitised albumenised paper exposed to the action of the three primary with their complementary colours," and then proceeds to compare the effects produced upon the albumenised paper and upon collodion; but in neither case is it stated what sensitising materials were employed, or whether they were identical in both cases—an omission which appears to us to nullify the value of any observation. We take it for granted that the light was allowed to act on both surfaces by transmission through coloured media; but we would direct attention to the fact that the nature of the colouring matter employed materially influences the result. It was demonstrated, at a meeting of the Blackheath Photographic Society, that porcelain slabs, tinted in various colours, by means of vitrification in contact with oxides of different metals, when photographed presented some curious contrasts; but especially that, in one instance, where the same colour to the eye was produced by two various metallic oxides, when photographed a marked difference in the result was noticed. This point does not seem altogether to have escaped the notice of Mr. Clarke, for he makes allusion to the subject in connexion with red flowers; but he regards it as "unaccountable," while no mention is made of the fact that the presence or absence of bromides or chlorides in the same "vehicle" materially influence the sensibility to certain of the coloured rays.

We trust that upon some occasion, at no distant time, probably in continuation of the previous paper, Mr. Clarke may furnish the missing particulars, and thus render available for future use that which at present is too incomplete to act as a safe point of departure towards further conclusions.

The mounting of photographs has always proved a minor trouble to amateurs: it is generally regarded as a "messy" job and a piece of drudgery. But for the unpleasant scent of turpentine, which very pertinaciously adheres to proofs mounted with the india-rubber solution, we regard that material as the best for the purpose, although it requires a little knack in its application. We have, however, been much pleased with an elegant method suggested by Mr. J. Stuart, of Glasgow, in a paper *On Printing and Toning*, published in our last Number, pp. 114 and 115. It consists in covering the backs of the proofs with *patent starch paste*, and allowing them to dry. After trimming the edges they are ready for mounting, thus:—With a wet sponge damp the cardboard all over, apply the print to be mounted in the proper place, put the two faces downwards on a lithographic stone, cover with the tympan and pull through the press. Mr. Stuart asserts that he can thus mount 100 in an hour, and we have no doubt that he can. We think this plan deserves attention, and as for the absence of a lithographic press being a difficulty, a very simple substitute could be got up at a moderate cost that would perfectly carry out the principle involved. Other adhesive materials might even be employed in a similar manner: it is the method of operating which is new to us.

We have with this number the pleasure of placing before our readers a specimen by the new process devised by Herr Paul Pretsch, for producing blocks for illustration that are adapted for surface printing by the common printing-press, or "platen"

printing machine, in conjunction with the ordinary type. The specimen now given has been printed at a "platen" machine, driven by steam power. It must not be forgotten that this is no attempt to supersede photographic printing, but simply to apply photography, in connexion with the electrotype, to the illustration of periodical and other literature in the same manner as is now in common use with wood-cuts. For subjects having much elaboration of detail, the gain both in time and cost may be reckoned as very considerable, even in the present state of the process; but, as the inventor is still continuing his labours on it, further advantages may yet be anticipated.

ON THE PROCESS OF MESSRS. PETSCHLER AND MANN; ALSO, ON TWO EFFECTS PRODUCED BY A CONTINUED ACTION OF THE SAME CAUSE, VIZ., NEGATIVES CHANGED INTO POSITIVES.

By J. Kibble.

[Read before the Glasgow and West of Scotland Photographic Society.]

The intense interest excited by the communication of Messrs. Petschler and Mann, at one of the Manchester Photographic Society's meetings, on the destructive influence of a coating of chlorided albumen when in contact with the ordinary washed sensitised iodide of silver surface, induced me to make a few experiments to satisfy myself to what extent the chloride rendered iodide of silver non-sensitive to light, as, from former experiments on the destruction of actinism, I had arrived at a conclusion somewhat different to the general opinion formed by their experiments. So as to prevent any misunderstanding of the few remarks I am about to make, I may state that plates prepared as follows, viz., sensitised, washed, coated with chlorided albumen (two grains to one fluid ounce), dried, exposed for several seconds to the influence of unobstructed daylight, immediately washed to remove the albumen; exposed for two minutes in the camera against an object; after exposure, flooded all over with a fifteen-grain solution of nitrate of silver, developed with the ordinary protosulphate of iron developer—will, in about one minute, be as free from all fogging as if the sensitive surface had been subject to actinism in the camera only. Yet, notwithstanding, as my after experiments will prove, the iodide of silver *is* sensitive to light when in contact with chlorided albumen; but is so far retarded by the chloride on washing, that an image formed in the camera, subsequent to washing off the albumen, will completely develop with a proto-salt of iron, before the previous action of light on the unwashed plate has time to manifest itself. In proof, a sensitised plate, washed, coated with the chlorided albumen, after being drained and dried by artificial heat in the dark chamber, and, while still warm, exposed in the camera for two minutes against a building about fifty yards distant, immediately on being taken from the slide, was washed under the water tap for one minute; a fifteen grain solution of nitrate of silver was then poured over and off it; the iron developer being applied, in about three minutes the high lights of the image made their appearance; in about two more all the details were *distinctly* visible. Although by no means such a negative as an aspirant would relish, it was quite sufficient to prove that iodide of silver is sensitive to the actinic rays when in contact with chlorided albumen.

These statements may appear a little paradoxical at first, but can be explained in a very simple and satisfactory manner. Imagine a sensitive surface (such as the ordinary wet process gives) to be exposed in the camera *twice*, each time to a different object; the first exposure to be one *second*, the next one *minute:* it is quite obvious, on the developer being applied, the longest exposed will make its appearance and thoroughly develop before the slightest trace of the shortest exposure becomes visible. Now, if the developing be discontinued, it might be said the short exposure had not any effect: neither has it, as far as visibility is concerned; but had the development been continued, it assuredly would have manifested itself, and a confused image have been the result. This, in one sense, I consider quite analagous to the unwashed and washed collodio-albumen plates, the whole being caused by a mere difference or increase in the time of development: in one instance, by the retarded chloride on the *long* exposure; in the other, the *short* exposure acting similarly to a retarder in giving slow development. The actinism under exposure of unobscured daylight is so far destroyed by the act of washing off the chlorided albumen—which will, on entering into solution, exercise its maximum chemical effect—that an image formed in the camera by a few seconds of action on the *washed* iodide of silver will, under the developer, manifest itself, and thoroughly develop without being interfered with by the actinism of exposure to open daylight, which is retarded, or partially destroyed, by the chloride, in addition to that, the dry iodide of silver not being so sensitive. But to this there is a limit, as the following highly-interesting experiment will prove:—Expose one of the unwashed collodio-albumen plates (which has been prepared in the dark chamber) for *four* minutes to the influence of an image in the camera. Having done so, wash it under the water-tap for one minute, and again expose in the camera to the same object; but this time let the plate occupy a position at a right angle to what it did formerly, and let the exposure be *one* minute, or one-fourth of previous exposure. This effected, pour over the plate a little of a fifteen-grain nitrate of silver solution: after having inclined it in all directions, pour it off, and flood all over with the iron developer. Now mark the result: towards the expiration of two minutes two images become visible, at a right angle to each other, as nearly as possible of the same intensity.

After having developed for two minutes, should the image not be bold enough, wash off the decomposing fluid, and repeat with silver and iron alternately until satisfied. The specimen I now produce was done exactly as given. You will observe there are four different specimens. The first was exposed in the camera for two minutes with the chlorided albumen in the *wet* state over it—a very satisfactory proof that even the wet chloride is only a retarder. The second is the same in every respect, but exposed twice to the same object:—first for *three minutes* in the unwashed state; the second time for *ten seconds* AFTER being *washed*—the plate also at a right angle to its former position. You will observe the longest exposure under the action of the chloride has developed without any interference from the short exposure on the washed surface; but in the third instance the result is very different, although all but the time of exposure is identical. Four minutes' exposure of the unwashed and one minute of the washed give as nearly as possible the same result: both images appear equally distinct. The fourth specimen differs from all the others in one respect only. After exposure, instead of washing with water, a weak solution of nitrate of silver was used for that purpose; the object being to convert the chloride of sodium into chloride of silver in the act of solution, so as, if possible, to destroy the action of the salt on the latent image. In this instance, also, the image developed but slowly; indeed the obstruction presented to the developer by the coagulated albumen holding chloride of silver embodied in it rendered the experiment comparatively worthless. To obtain satisfactory results, the chlorided albumen should be thoroughly washed off previous to using a developer which contains silver. The sixth plate, you observe, is an ordinary collodio-iodide of silver (no albumen), which was washed, and, after drying by artificial heat, exposed in the camera for two minutes; taken from thence, steeped in water, exposed again for *one* minute, at a right angle to former position, then flooded with weak nitrate of silver. On applying the developer, both images appear simultaneously, and of nearly equal force. In a former experiment, in which the times of exposure were the same, the one image came out much in advance of the other. As far as these experiments go, the dried iodide of silver appears to have lost one-half of its sensitiveness which it gains on being wetted. It is more than probable both states have lost their sensitiveness to a certain extent by the drying.

The day on which these last experiments were made was so dull from fog that distant objects could not be taken with the camera; hence the reason that a lithographic portrait was made use of. Should similar experiments give similar results with others, the question naturally suggests itself—Will this process be suitable for instantaneous results? This I leave for those who pursue this fascinating science to ascertain. It must be borne in mind that all of the above experiments were exposed and developed immediately after preparation. It is possible, indeed highly probable, that sensitive surfaces which have been exposed to the influence of light, and retained in the dark chamber or box for days previous to development, may have the action, which in my experiments is only retarded, wholly destroyed by the prolonged action of the moist chloride. But that point also I leave for some of you who have better opportunities than I have to investigate.

I now beg to call your attention to some remarks I made at one of our former meetings under the title of *Influence of Light and Heat in Changing the Physical Properties of Bodies*, where I state:—"It is well known to all of you that a certain amount of exposure of one of the sensitive surfaces, viz., iodide of silver, to the actinic rays produces a certain effect which is again destroyed by a prolonged exposure. Indeed I attribute the great success in producing what is

termed instantaneous results to accident in shutting off the exposure in the camera at that particular time when the intense light, such as from clouds and water, at the angle of reflection has, as it were, to a certain extent neutralised the actinic force after it had reached its maximum—the action of the high lights *decreasing*, whilst the feebler lights *increase* their force." I now lay before the meeting a proof not only of its being possible to balance the action of an intense and a feeble light, but to cause the feeble lights to make their appearance under the developer first as *positive*, and the intense lights to come out slowly afterwards as the negative portion of the image. In the specimen exhibited you will observe there are two objects at a right angle to each other. The positive was obtained by an exposure of *ten* minutes, the negative by *one* minute. When the intense light of the face in the *second* exposure falls upon the intense light of the background of the *first* exposure, it subjects that particular portion of the sensitive surface to actinism for twelve minutes, or the combined exposures. The intense light acting continuously for such a time appears to have neutralised the action established to such an extent that the feebler lights, not having exercised their maximum effect, but continually increasing in force, take the position of the high lights under moderate exposure, and come out first; the reduced action by over-exposure appearing last. I trust it will be understood that all the remarks I have here made apply to the experiments the results of which I have now laid before the meeting. I had many more to make, but the foggy state of the atmosphere wholly precluded me from doing so. To Mr. Alexander M'Nab I am very much indebted for the use of his laboratory, also for the time and trouble he expended in manipulating, I being a mere looker-on during the operations. I observe he is present and can testify to all I have stated. On some future occasion I trust to have the pleasure of entering into the second branch of this subject, or its converse, viz., *two* causes producing *one* effect.

I am of opinion we ought as a society to give a vote of thanks to Messrs. Petschler and Mann for the very unreserved manner in which they have given their interesting discovery to the photographic world.

ON THE APPARENTLY INCORRECT PERSPECTIVE

OF PHOTOGRAPHIC PICTURES PRODUCED BY LENSES OF DIFFERENT FOCAL LENGTHS,

As usually viewed or looked at, which may be considered as a kind of Apparent Distortion.

By J. Rothwell,

Inventor of the Method of Constructing Photographic Lenses free from Distortion.

[Read at a meeting of the London Photographic Society, November 6th, 1860.]

In commencing, I wish to observe that, although some few photographers understand all that I shall attempt to elucidate, yet the great majority, not having studied optics, are completely mystified to account for the anomalies of which I am here trying to show the causes, the why and wherefore. It is a common remark by people that such and such objects are too large or too small, and the answer generally is, that "it is only imagination; it is correct, and cannot be wrong: it is impossible." But I think I shall here prove that almost all photographic pictures are more or less incorrect apparently.

I propose to treat the above subject under three heads:—

1st.—The apparent enlargement of objects approaching the margin, and diminution of those about the centre of photographic pictures produced by lenses of short focal lengths, by which I mean those under twelve or fifteen inches; and, on the contrary, the apparent enlargement of objects about the centre, and diminution of those near the margin, produced by lenses of long focus—those over twelve or fifteen inches.

2nd.—The apparently excessive enlargement of *near* objects, and extraordinary diminution of *distant* ones.

3rd.—The monstrous enlargement of objects approaching the margin, caused by those objects being out of focus, in addition to that caused by their being situated in the margin, as demonstrated under the first head.

I am supposing the lenses to be without distortion on my principle, as illustrated in a paper read before the Photographic Society by J. H. Dallmeyer, Esq., optician, and not the common view-lens, or portrait combination, which would further complicate the matter by their distortion.

Proposition 1.—*Theorem.*

In the first place I assert that in looking at all photographic pictures, to be seen in correct perspective, the eye must be placed at the point where the aperture of the stop was when taking the picture.

It is an incontrovertible truth in optics that the *angle* under which an object in a picture is seen, to be correct, must be exactly the same as the angle under which the object itself is seen in the natural view, whether that object be a near or a distant one.

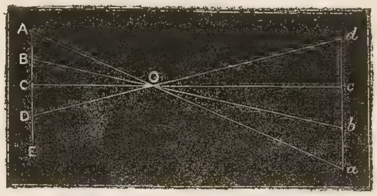

FIG 1.

In *fig.* 1, A E is the picture or plate, and O the aperture of the stop; *d c*, *c b*, *b a*, objects seen under the angles *d* O *c*, *c* O *b*, *b* O *a*; and A B, B C, and C D, the images of those objects as seen under the angles D O C, C O B, and B O A. Now it is demonstrated by a well-known theorem in geometry, that angles on the opposite sides of a straight line D *d*, bounded by the same straight lines D *d* and C *c*, are equal; therefore the angle D O C = the angle *d* O *c*: and so also with the other angles. It is axiomatic that the picture object D C will appear of the same proportionate length and breadth as *d c*, the object itself; therefore, under its true dimensions in all respects when looked at from O, whether the picture be near or distant, that is, taken with a long or short focus lens.

And to prove this more completely, and also to prove that, when the eye looks at a picture from any other point than that above indicated, thereby causing apparent distortion, and, in the particular case stated below, to show the amount or actual variation from true perspective, we must investigate fig. 2, which will require close attention, as the subject is somewhat complicated and elaborate.

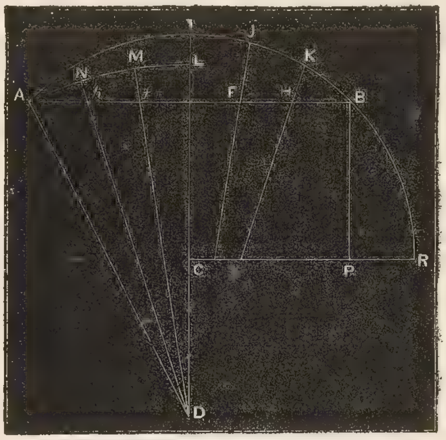

FIG 2.

Proposition 2.—*Problem.*

Referring to the right-hand side of the *fig.* as C I R, A B is the plate or picture, twelve inches across (I am supposing we are looking across the plane of the picture); I D the axis, perpendicular to the plate; E C is six inches, the focal length of the lens with which the picture was taken: therefore C E B is a right angle; and to find the hypothenuse, by the theorem on right-angled triangles, $\sqrt{}$ [(E B, half the length of the plate, 6 inches)^2 + (E C, 6 inches)^2] = C B = 8,4852. Now, using C B as a radius, strike the arc R B I A, then draw the line or radius C R perpendicular to the axis I D, by which it will be parallel also to E B; then draw the line B P perpendicular to C R and E B, by which it will be parallel to E C; then C E B P is a square, and therefore B P = E C = E B, consequently as the sine B P = sine E B, the arcs R B and B I are equal by proposition in trig., and as the angle I C R is a right angle, the arc I B R = 90°, by cor. to def. in trig.; and therefore, as the arc I B = the arc B R and the two together being = 90°, the arc I B must be 45°, being the half of 90°. Divide the arc I B into three equal

parts or segments, then each of those equal segments will $=15°$. Lastly, draw the lines C J and C K, cutting the picture in F and H. I have taken a very wide field of view—90° (I have included between 80° and 90° in a number of pictures on flat plates), whereby to show and explain the matter more palpably.

Now, the eye placed at C, looking at the three divisions of the picture, E F, F H, and H B, they will appear all of the same size, in consequence of the three angles being equal: and yet those three parts are not actually equal; to prove which I now proceed to ascertain their exact lengths, which is the problem to be solved.

By proposition in trigonometry, "In any triangle, the sides are to one another as the sines of the angles opposite to them," and by inversion (by problem in geometry, C E F being a right angle, the other two angles E C F and F E C are equal a right angle; therefore, E C F being equal 15° by construction, subtract this from 90°, which leaves the angle E F C = 75°); and as ·933, sine of $\angle$ E F C, 75°: Side E C, 6 inches : : 2588, sine of $\angle$ E C F, 15° : Side E F = 1,6643, which is one of the divisions of the half picture E B. Again, by the same proposition in trigonometry (and by the same problem in geometry), subtract the $\angle$ C H E = $\angle$ E C F, 15° + F C H, 15° by construction, = 30° from 90°, there remains the $\angle$ E H C = 60°; therefore, as ·866, sine of $\angle$ E H C, 60° : Side E C, 6 inches : : 5, sine of $\angle$ E C H, 30° : Side E H = 3,4642; and by subtracting E F, 1,6643, from E H, 3,4642, there remains 1,7999 = F H, the middle part of the half picture E B. Next subtract E H, 3,4642, from E B, which by construction is six inches, and there remains H B = 2,5358, the other division of the half picture E B.

We have now solved the problem, and found the lengths of the three divisions of the half picture E B, viz.:—

$$\begin{aligned} EF &= 1{,}6643 \\ FH &= 1{,}7999 \\ HB &= 2{,}5358 \\ \hline & 6{,}0000 = EB; \end{aligned}$$

which was the thing proposed to be done.

Proposition 3.—*Problem referring to the left-hand side*, D I A, fig. 2.

Suppose the eye to be now placed at D, twelve inches from the plate, and looking at E A, the left-hand half of the picture. Divide E A into three parts respectively equal to the three parts into which the right-hand half of the picture is divided, the lengths of which I have found by the preceding proposition. Thus, make

$$Ef = EF,\ fh = FH \text{ and } hA = HB.$$

Find the hyp. of the right-angled triangle D E A, thus:—

$$\sqrt{(AE,\ 6\text{ in.}^2 + ED\ 12\text{ in.}^2)} = DA = 13{,}4164.$$

Now, taking D A as radius, strike the arc A L; next draw the lines DfM and DhN. The problem is to find the angles EDf, fDh, and hDA, to discover whether the parts Ef, fh, and hA (as seen under those angles from D) appear equal, as they did when viewed on the right-hand half of the picture from C, and if not, to what extent they vary from equality, and consequently from true perspective. Find the hyp. Df of the right-angled DEf, thus:—

$$\sqrt{(ED\ 12^2 + Ef,\ 1{\cdot}6643^2)} = Df = 12{\cdot}1062;$$

then, calling Df radius, as Df 12·1062 : Ef, 1·6643 : : 1 : nat sine = ·1374 = 7° 54′ $\angle EDf$. Find the hyp. Dh of the right-angled triangle DEh, thus:—

$$\sqrt{(ED,\ 12^2 + Eh,\ 3{\cdot}4642^2)} = Dh = 12{\cdot}5;$$

then, calling Dh radius, as Dh, 12·5 : Eh, 3·4642 : : 1 : nat sine = ·2771 = 16° 5′, $\angle EDh$; therefore

$$\angle EDh,\ 16°\ 5' - \angle EDf\ 7°\ 54' = \angle fDh,\ 8°\ 11'.$$

Again, as D A, 13·4164 : E A 6 inches : : 1 : nat sine, 4472 = $\angle$ E D A, 26° 34′; therefore, $\angle$ E D A, 26° 34′ − $\angle EDh$, 16° 5′; = 10° 29′, $\angle hDA$.

We have now solved the second problem, that is, ascertained the angles EDf, 7° 54′ + fDh, 8° 11′ + hDA, 10° 29′ = 26° 34′; and by dividing 26° 34′ by 3, we have three equal angles of 8° 19′ 30″ each; and to see the three parts of the half picture E A with the eye at D, all apparently of the same size, as we did with the eye at C, it is evident that each should be viewed under the equal angle 8° 19′; but instead of this we have the angle EDf 7° 54′, that is, 25′ too small; the angle fDh 8′ too small, and the angle hDA 2° 10′ too large.

By the foregoing synthetic course of reasoning, I have demonstrated indisputably that all photographic pictures, particularly those taken with short focuses, when looked at from a greater distance than the focal length of the lens with which the picture was taken, appear under incorrect perspective, that is, the marginal objects appear too large and the central ones too small; and, on the contrary, it is also evident (which can be proved) that when any photographic picture is viewed from a shorter distance than the focal length of the lens with which the picture was taken, the central objects will appear too large, and the marginal ones too small. The general conclusion to be deduced is, that it is not advisable to include a wide field with short focus lenses, except in taking groups in some cases, and in which the operator has not sufficient distance to place his camera. But in taking pictures with long focuses (12 inches and upwards) there is no objection to include the widest field possible, because a picture taken with a 12-inch focus will be of such size that, to look at all the picture at once, it will be held at least that distance from the eyes, and therefore appear correct; and so on with longer focuses and larger pictures.

2. The apparent enlargement of near objects and diminution of distant ones.

I have two (what I conceive to be satisfactory) explanations on this subject. The first is, that near objects, in the majority of views, are situated near the margin, and distant ones in the centre; and if the picture has been taken with a short focus, I have demonstrated in the three preceding propositions that in this case, that is, when the near objects are in the margin, those near objects will appear too large, not because they are near, but in consequence of being in the margin, and that the distant objects, being in the centre, will seem too small.

The second explanation is, an optical illusion, which I will elucidate presently.

I believe that it is a universal practice with all photographers in taking views—yes, and groups too—to so arrange matters as to have near objects about the margin, and distant ones about the centre, if possible. Why? Every photographer knows why,—simply by so doing to get everything in good focus, in consequence of the curvature of the image; and from this practice, and what I have previously demonstrated, the majority of pictures have the evils the causes of which I have made manifest in this paper.

The second explanation, the optical illusion, is that the eye, when looking at a distant object, has not, at the same instant, a clear impression of a near object, because of that near object being out of focus in the eye; the result of which is that we do not get a strong, clear, or correct notion of the comparative sizes of near and distant objects at the same instant. Suppose two poles of equal lengths, both in the centre of the view, one at ten yards distant, the other at forty yards. If we look at the near pole, the eye accommodates itself to that distance to bring it into good focus,—*i. e.* clear sight; but, by so doing, it puts the distant pole out of focus, makes it indistinct, and *vice versâ*, by looking at the distant one; and our notion of the comparative sizes of the two poles is acquired by looking first at one pole and then at the other. But in looking at the images of the poles in the picture, the case is altogether different, for there the images are both the same distance from the eye (being both in the centre); and, in consequence of this, the eye gets a distinct view of both at the very same instant, whereby, and for this reason, we are struck with the comparative—apparently excessive—unnaturally great difference betwixt the sizes of the images, or pictures of the poles.

From this explanation of this optical illusion, it is manifest that it is immaterial in what part of the picture the poles or other objects are situated; but when the two causes are conjoined, as in the picture of a long street-view, then it requires both the first and second explanation to account for the very great and apparently incorrect perspective. In the case of a picture having a near (large) object in the centre, and distant ones receding towards the margin, the apparently incorrect perspective of such a picture is, to some extent, corrected by the same causes which produced the bad perspective in the case under propositions 2 and 3, and what remains uncorrected is readily explained by optical illusion. The apparently incorrect perspective of the picture of a long row of houses standing obliquely across the picture is easily explained by the first and second explanations together; for the near end of the row appears too large, because it is in the margin, and the farther end seems too small, by reason of optical illusion, although it is corrected to some extent by being in the opposite margin; for, if we look at the farther end, we do not see, at the same instant, the near end clearly; and *vice versâ;* but, in looking at the picture, we take in the whole view of it at once, and then occurs the optical illusion.

Under this head, too, I may refer to the case of the great—shall I say hideously deformed?—images of objects (the objects themselves not being in the same plane) produced by placing the camera very near those objects when taking them, whether using long or short focusses. The worst features of this case occur, almost universally, when taking a single portrait—that is, a portrait of one person.

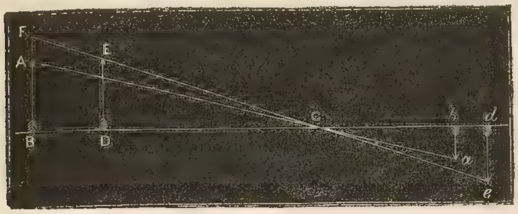

FIG 3.

Proposition 4.—*Problem.*

In *fig.* 3, suppose A B to be an object 18 inches long, and 6 feet from the camera, C the aperture of the stop, and $a b$ the image of A B. Now, remove the object A B 18 inches nearer the camera, and place it at D E; its image, in consequence, will be enlarged (and advanced to $e d$) in the proportion of D E to B F, or $b a$ to $e d$; required, the quantum of enlargement. Because (by theorem in geometry), D C E and B C F are similar triangles, and C D = C B 6 feet—B D 18 inches; therefore C D = 4 feet 6 inches,—thus, as C D, 4 feet 6 inches : C B, 6 feet :: D E, 1 foot 6 inches : B F = 2 feet; and therefore D E, or $e d$, appears one-fourth larger. Now, if we suppose in the case of a portrait of a single person, the hands at D E, and the head at A B, or still further off, it is evident that the head will be considerably too small, and the hands a great deal too large, and that, to get the portrait approximating anything near apparent correctness, when the camera is placed so near, everything (head, hands, knees, &c.) must be nearly in the same plane. Let the camera be placed now four yards from the sitter, and, by the above reasoning and similar calculation, it will easily be found that the object D E will be enlarged only one-eighth of an inch, or half of that of the above case; therefore it is quite manifest that it is better to place the camera at four yards distance, using a longer focus to produce the same size of picture, than to place it at two yards distance, using a shorter focus to produce the same size of picture; in addition to which, there are the evils under propositions 2 and 3.

3. The monstrous enlargement of objects approaching the margin, caused by those objects being out of focus, in addition to that caused by their being situated in the margin, as demonstrated under the first head; and sometimes, also, may be added the evils caused by the camera having been placed a very short distance from the sitter, as explained under proposition 4.

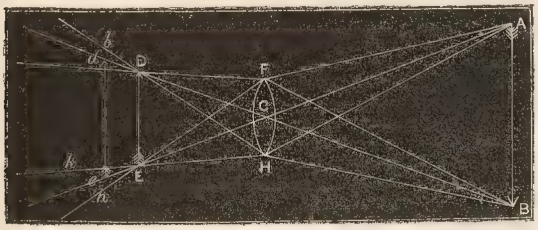

FIG 4.

Fig. 4.—Suppose A B to be the object, D E the image of that object in proper focus, and $e d$ the image out of, and beyond, the focus, F H the lens, and C its centre. Now, if we take the cone of rays, F A H, issuing from the point A, and, after passing the lens, being concentrated at E, and then, after passing E, diverging to the points $k e h$, forming there an indistinct scattered focus, it is evident that, by the outermost ray diverging to h, the image will be thereby indistinctly extended beyond what it ought to be,—that is, it comes to h instead of to e; and so also with the other cone of rays, F B H, being concentrated at D, and then the outermost ray diverging to b instead of to d, by which means the whole image will be indistinctly and greatly enlarged above its natural size. Now, if we suppose A B to be the hand of a sitter, it is quite plain that that hand will be indistinctly and greatly enlarged; and so also will it be with any other objects similarly situated,—thus proving what I asserted under this head.

I should scarcely consider this paper complete without showing the causes of the incorrect, the shocking bad perspective of vertical near objects, especially tall ones,—such as high square towers being converted into the frustrums of quadrilateral pyramids, buildings apparently tumbling into streets, &c., &c., caused by what is commonly called "cocking the camera."

All vertical objects ought to be photographed, if possible, with the axis of the lens horizontal. Suppose a tall square tower, the lens, with its axis horizontal, E F the plate, vertical, and parallel to the tower. Now it is evident that, in taking a picture of the tower in this manner, the image of the upper part of the tower will be situated in the margin of the picture, and the image of the lower part of the tower near the centre; and, in consequence of what I have demonstrated under propositions 2 and 3, the upper part of the tower will appear too large, and the bottom too small; and I have shown, under the second head, that, on the contrary, by optical illusion, the upper part of the tower, being the most distant, will appear too small, and the lower part, being the nearest, will appear too large. Now it is very evident that one of these evils will counteract the other, and the result is that we obtain a picture approximating to correctness, which will be found to be the case by experiment.

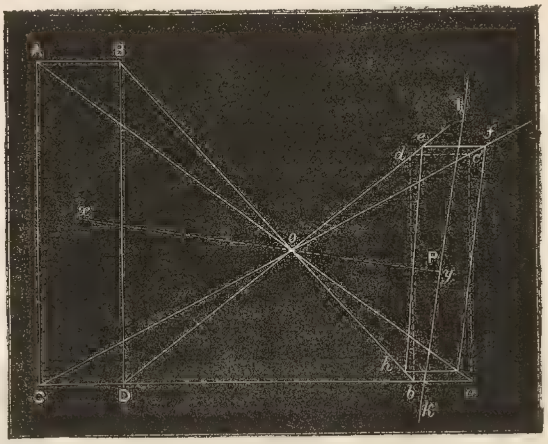

FIG 5.

In *fig.* 5, we will suppose the axis, $x y$, to be pointed to x at half the height of the tower, and the plate inclined to the perpendicular, as at I k. Now it is evident that, by the plate being so inclined, the lower half, P k, will cut the angle $b o a$ at $h g$,—that is, nearer its vertex o, and, as a sequence, $h g$, which subtends that angle, will be shorter than $b a$, which also subtends the same angle,—that is, the width of the tower will be narrower at $h g$ than what it was at $b a$, and by similar reasoning it will be plain that the image, $e f$, of the lower part of the tower will be larger than what it was at $d c$; thus, by "cocking the camera," and directing the axis upwards, the shape of the picture of the tower becomes that of a frustrum of a quadrilateral pyramid,—that is, the corners of the tower incline inwards from the base upwards, and yet, notwithstanding, the corners from the bottom to the top remain straight lines. This case, considered vertically, is exactly similar to the long row of houses standing obliquely to the plate (referred to under the second head), and considered horizontally.

We have only to suppose the open end of a street substituted for the tower, and, by the reasoning under *fig.* 5, it will be readily comprehended that the corners D A, C B of the buildings at the corners of the street incline outwards into the street from the base upwards, as if they desired to come down together into the middle of the street.

In conclusion, I wish to observe that a photographer is surrounded, as it were, with numerous evils in connexion with his lenses and mode of operation, and it has often been remarked, in relation to lenses, that "if you gain one advantage, you lose another,"—and so it is; and in this paper my object has been to show the causes of some of those evils, and to enable him to avoid them as much as possible, thereby to obtain the best and most correct results.

ON THE MECHANICAL ADAPTATION OF PORTRAIT LENSES FOR VIEW PURPOSES.

By C. Jabez Hughes.

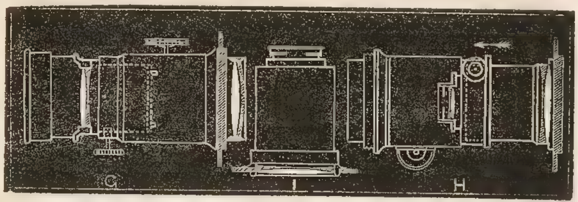
[Read at the meeting of the South London Photographic Society, October 18th, 1860.]

Many persons attach great merit to the fact that they can use the front lens of their portrait combinations as a single or landscape lens, it being a well-known fact that the general form is similar. It should be remembered, however, that in taking portraits the convex surface is turned outwards to the object, but for views it is turned inwards towards the camera. The size and position of the diaphragms being also different in the two cases, the mounting of the lens must vary according to the purpose for which it is to be used. I do not propose here to discuss the advisability of thus employing lenses: it is sufficient that they can be and are so used, and that different makers have exercised great ingenuity in adapting their brasswork for the purpose. To these various devices I propose to invite your attention, and I think we shall have occasion, in passing them under review, to express our admiration of these adaptations. Almost every maker has his own method, and some have patented their plans. Let us take first one of the earliest and best makers, Voigtländer, and see how he accomplishes the task. He first separates his tube from the flange; into this flange he screws an *adapter*, that is, a brass ring with a smaller aperture: the front portrait lens is then removed and screwed from the back into this adapter; a brass cell with small diaphragm in front is then pushed on to the lens, and it is ready for use.

[Mr. Hughes then changed the various parts of a Voigtländer lens, as described, and handed it round to the members. This arrangement, though ingenious, is so very inferior to the devices of other makers, that we are contented with giving the above description. In some of the more remarkable adaptations we have used diagrams to render the description more clear.]

Ross adopts a more simple plan. He removes the hood from the front, unscrews the back lens, and reversing the cell containing the front lens, puts it in the place of the back lens; a series of diaphragms are then fitted in and it becomes a complete single view lens. The rack-work is made thus equally serviceable for landscape and portraits, and the body of the tube serves for a hood or shade. This plan is very simple and efficient, the cell with diaphragms being the only additions to the portrait combination.

[Mr. Hughes handed round one of Ross's No. 2 lenses fitted as described.]



[In the above diagram A shows a section of the Ross portrait combination; B represents the front lens reversed with the additional diaphragms for landscape uses. It is but just to Mr. Ross to mention that though he kindly supplied Mr. Hughes with an example of this mode of mounting, he does not recommend his front lens to be thus used generally, but prefers to supply a separate lens better adapted for the purpose.]

Horne and Thornthwaite have a different method. They take out the front portrait lens, and, reversing it, screw it into a regular single lens brasswork, and, except with the flange, make no attempt to use the portrait lens brasswork.

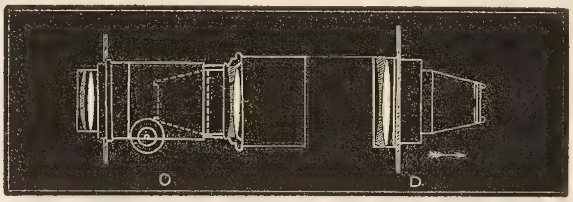
[One of Messrs. Horne and Thornthwaite's lenses was handed round, in illustration, and was in no respect different in its mountings to an ordinary single landscape lens.]

Lerebour, I believe, has two different arrangements for this same object. Neither of his plans, I am assured, are remarkable for ingenuity. I am sorry I have not been able to secure one to show you. Lenses of this adaptation by this maker are not common.

The late C. Shepherd adopted a neat arrangement. It is still manufactured by the firm bearing his name, and to whom I am indebted for the example shown. It is somewhat in the rough, being got up at short notice for this meeting; but you will perceive the principle is still the same, using the front portrait lens reversed, and placing diaphragms in front.

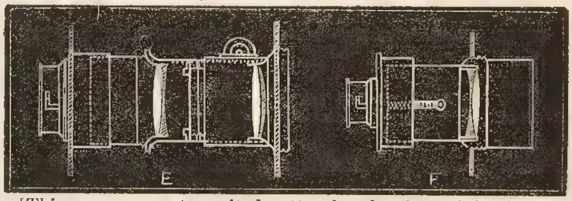
[This arrangement being rather antiquated, and moreover, open to some of the objections made against it in the course of the discussion which followed, we have not thought necessary further to describe it.]

The introduction of central diaphragms has enabled many opticians to combine appliances to serve both purposes. For example, here is Millet's arrangement:—At the back of his front-portrait lens he attaches a tube, and at the end of this tube is the central diaphragms. When this front lens is removed, and reversed for landscape work, the same tube is in its proper position, and furnished with stops.



[Diagram O shows section of Millet's ordinary portrait lens, the central tube indicated by dotted lines; D shows the arrangement for landscapes.]

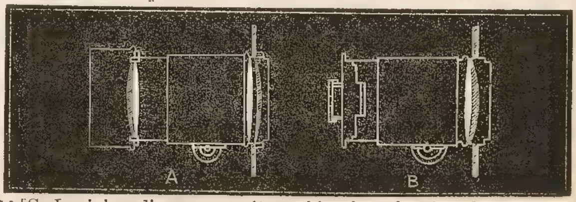
Hermagis, in his patented method, has made a very daring innovation. He cuts his tube in two parts, right through the rack, midway between the lenses. One of these screws into the other, and the stops are introduced at the intersection. When required for single lens purposes the two halves are separated, the back one removed from the flange, and the front half screwed in its place by means of a thread left on the hood; the diaphragms are then in their proper place, and, by an ingenious arrangement, that which formed the cap of the portrait lens becomes the hood and cap also of the single lens.



[This arrangement excited attention by its originality and ingenuity. E shows the Hermagis portrait arrangement; F, the adaptation for landscapes.]

Most of you will remember a peculiar and cumbrous mode of mounting his lenses that was patented by Jamin; the back lens being larger than the front, and having what he called a "centralising cone." In this arrangement the tube was in halves, one screwed on from the outside of the camera and the other from the inside. But though clumsy and inconvenient it was the foundation of his present method, which is certainly the most elegant and ingenious that has come under my notice. In this lens we have for the first time three lenses instead of two. Midway between the front and back lenses is an arrangement for central diaphragms, or for this third lens. This latter may be used or not in connexion with the portrait lenses, but its main service is in connexion with the front lens used as a landscape lens. It shortens the focus so that a sharp flat picture can be obtained in the usual camera, whereas the ordinary single lens requires an unusually long camera to be employed. The arrangements for changing the parts are very simple. By means of an extra tube the front and back lenses are instantly attached or detached. It is difficult in words exactly to describe it, but you see the instrument in my hands and the ease with which the several parts are transposed.

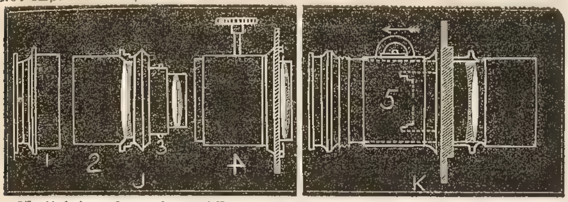
[Mr. Hughes here described minutely the different appliances of Jamin's Patent Treble Portable Combination, which excited great admiration.]



[G, Jamin's ordinary portrait combination, showing the arrangement for central diaphragms or additional lens; H, the Jamin

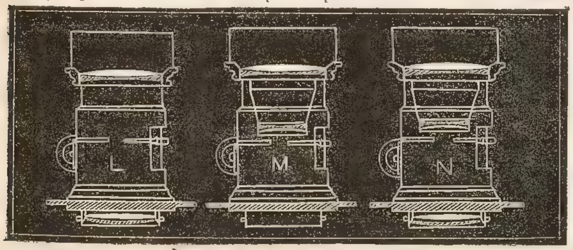
orthoscopic or double landscape adaptation; I the single lens arrangement of long focus for large pictures.]

The next lens I introduce is Derogy's. In this arrangement more is attempted than any other. The lenses consist of the usual portrait combination and two additional ones—one for lengthening, the other for shortening the focus. First we start with the usual portrait combination as it is now. To make a smaller or larger picture we separate the lenses, which is very easily done by these bayonet joints, and insert the long or short focus supplemental lens. To use it for single-lens purposes we separate them thus (disconnecting them), and remove the back lens, and in its place put the front lens reversed; to increase or decrease the size of the picture one or other of the supplemental lenses is to be used in addition. The whole arrangements are very simple; but, whether more is attempted than can readily be reduced to practice, I will not express an opinion.



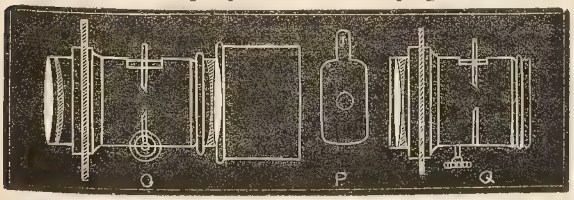
[J, disjointed section of Derogy portrait lens, showing—1, cap of lens; 2, front half of portrait combination, with bayonet point in section; 3, position for central diaphragms or additional lenses to lengthen or shorten the focus (a lens *in situ*); 4, back half of portrait combination, which unites withfront half, 2, by bayonet point. K, Derogy lens for landscapes; 5, position for diaphragms, or additional lenses to increase or decrease the size of pictures.]

The next lens is Mr. Slater's, with his Petzval Combination. It consists of the usual portrait combination with a negative focus lens used between. It makes an excellent instrument for groups when the central lens is used, as it gives more generally distributed definition than any other I know of, and is the only lens I have used that gives the head, feet, and centre of the body of a standing figure sharp at the same time. This peculiarity is entirely due to the central lens. To use it for landscapes it is only necessary to remove the back lens. It is provided with Waterhouse stops that are equally suitable for landscapes or portraits.



[L, Mr. Slater's ordinary portrait combination, showing Waterhouse stops; N, the same combination, but with a negative focus achromatic lens inserted in the centre forming the Petzval arrangement; M similar to N, but with the back lens removed, forming an orthoscopic and landscape lens.]

Before I conclude, allow me to introduce one other lens that is as remarkable for its simplicity as some of the others are for their complexity. It is introduced by myself, and therefore I do not feel at the same liberty to dilate upon any of its merits. It is sufficient to say that it is the most simple and inexpensive of any on the table, and I feel convinced will be found in practice to be as efficient. It is only necessary to remove the back lens, place the front one in its place, and the portrait combination becomes a landscape lens, as the diaphragms are so placed that, without moving, their position is equally suitable for each purpose.



[O, Mr. Hughes's portrait combination, showing position of diaphragms; P, Waterhouse or central diaphragm; Q, landscape combination.]

I have now introduced to your notice the greater number if not all of the modifications adopted to use the front lens of a portrait combination for views; and though I should like on a future occasion to listen to a discussion on the fitness of the said lens for the proposed object, yet I think at present enough is before us to express opinion on the many ingenious plans to render yet more useful our already invaluable portrait combinations.

REMARKS ON FAILURE, AND SOME OF THE CAUSES OF FAILURE, IN ALBUMENISING, PRINTING, AND TONING OF PHOTOGRAPHIC PICTURES ON PAPER.

By James Ewing.

[Read at the Glasgow and West of Scotland Photographic Society, 1st Nov., 1860.]

Mr. Stuart, in his paper treating of the particular method by which he albumenised, printed, toned, and mounted photographs on paper, touched on one or two points relative to the cause of different phases of failure, which being again referred to by others of the members, caused some brisk discussion, and has induced you, sir, and the other members, to set aside this evening for the further consideration of the same. In opening the business of the evening, I hope, as I shall have occasion to refer to points mooted in papers previously read before this Society, that the gentlemen who have honoured us with such papers will not feel themselves aggrieved by such references, as it is in the spirit of a searcher after truth I shall do so—not from any personal motive or splenetic desire.

Science presents too noble an arena for us to enter on it encumbered with petty feelings, which only retard the progress of truth, and serve to dull the keenness of our vision in penetrating into the secrets of nature—secrets which, as we discover them, teach us how harmonious are her laws, and of how much benefit it would be to ourselves "could we the bright example take." In our particular branch of science and art—for photography is a combination of both—there are many difficulties to be overcome, requiring much patience, method, and cleanliness, as often, even with those valuable requisites, failures do occur. Consequently, as we have met together as a society for the furthering of the interests of photography, it is right that we should, with the spirit of friendly rivalry, endeavour to clear away such difficulties; and I do not think there is a better way of doing so than by calmly discussing our failures, tracing as nearly as possible their causes, prescribing a cure, or, if possible, showing how to avoid such failures *in toto;* and if we happen to differ in our opinions, as very likely we shall, let such difference not be mistaken for bad feeling, but rather as a desire on the part of all to wait for further evidence.

In times past it seemed to be a point with professional photographers, in serious conclave assembled, not to show anything but what was good in the shape of specimens: failure was only known in the sanctum or operating-room; and as soon as it appeared was most ungraciously put out of sight, and, if possible, tried to be forgotten. By this error much was lost—time, material, and, more, the chance of improving by the lesson of a recent failure; in fact, failure was only known in the columns of some photographic journal, where queries in regard to the cause of failure appeared under the quaint cognomens of "Young Photo.," "Old Hypo.," "Sel d'Or," or "XX.," which host of queries would have required the aid of some Athenian oracle to unriddle, instead of the attention of an ordinary editor. But things have altered. We know not why, except the couplet of Alfred Tennyson will answer, and it really appears to answer—

> "I doubt not through the ages one increasing purpose runs,
> And the thoughts of men are widened by the process of the suns."

And seeing that the business of photographers is so much mixed up with "the process of the suns," no doubt but their thoughts have become very much widened, and hence the change that they now boldly step out to show their failures as well as their successes; and perhaps the exposition of such failures may do more good for the advancement of the science than the quiet show of success arrived at through a labyrinth of difficulties misunderstood and uncared for. Let such difficulties be cleared away—success must follow.

If I am bothered with a difficulty and you know how to solve it, do so, and *vice versâ;* or if we are both bothered, let us put our

heads together to find it out. "Two heads are better than one," is the old adage, and it holds good even in this matter. Now I will tell you of a great difficulty which stands in our way, and that is a want of permanency in our productions: our toning and printing have not as yet given us anything that we can, with any assurance, term "permanent."

To make photographs as permanent as possible should be the aim of every lover of the art, the want of such permanence being one of the great barriers in the way to the adoption of costly photographs by the public in general; and it is one of the most particular items to which our attention should be directed, as by overcoming this difficulty photography will be placed on a surer footing, and be able to class with the sister arts—printing and lithography.

Perhaps some of the gentlemen present may have tried Sutton's process: rather over four years ago he claimed for prints produced by his method a degree of permanence not to be had by any other method, and which seemed to be highly spoken of at the time by Sir David Brewster. Mr. Sutton declared at that time that they were not only more permanent, but that they improved by age. Surely this was the great desideratum met, and yet I do not know of any one in Glasgow having adopted the process; although since then I have seen many beautiful photographs, which looked clean and imposing when first mounted, assume through time that "sear and yellow leaf" tint so annoying to photograph collectors. Certainly this fact demands great attention, as we are very far from having overcome this serious difficulty. What avails our printing and toning if we cannot get the pictures to last? What avails the softness of touch and the beauty of colour, exhibited by our first-class artists, if the pencilling on which they work evaporates in a few years, "leaving only a wreck behind?"

The contemplation of such a fact is very annoying indeed, and it begins to assume a more grievous phase when such theories as those given birth to by our President (and in one of which I am afraid there is too much truth) rise grimly before us:—"That the very salt we use as our fixing solution acts simply as a wash to thin the atoms or molecules which constitute the front of our picture, these atoms being covered with too thin a coating of gold to resist actinic action when mounted and exposed."

"In very presence of the regal sun" bursts the thin shell and evolves the very substance that gave the picture birth, to the entire destruction of the print—photographers' and artists' work. Such theories, when backed by plausible experiment, should be carefully conned over—tried if possible to be exploded—or, if their foundation rests on solid truth, let them serve to prompt us to greater exertion in the making our work permanent.

In printing it is always requisite to have a good negative, as you can never produce a good picture from a thin or misty negative. A great deal depends on this, as I assure you the alkaline bath cannot be used unless you have a good dense plate; if you have not, the resultant picture will be thin, bleached, and cold, but with a good negative you can produce fine results. Mr. Stuart's pictures, exhibited at the last evening of our meeting, were practical illustrations of such. The advantage this bath has over the *sel d'or* is, that there is less bother in connexion with it, less tendency to engender acid principles, and consequently it involves the chance of rendering the prints a little more permanent, which is a "consummation devoutly to be wished." With the *sel d'or* bath a moderately dense negative may be used and still produce a good picture, seeing that it does not require any overdoing of the print; but great care must be exercised in the process:—such as washing them for a long period in clean water, placing them in a bath of weak ammonia, washing again, toning in a solution of gold, hyposulphite of soda and hydrochloric acid; again washing in ammonia, again in clean water, at last fixing in strong hyposulphite of soda, and, finally, washing for a long period. With the old hypo. bath there was little or no trouble compared with either of the foregoing, and yet I have seen prints quite as clean and beautiful produced with it as with any of the former. It being the oldest method, its faults, in point of permanence, may be more readily observed. But when we place it before the theory of our President—a theory he kindly requested us to consider, and which, if correct, gnaws at the root of our whole art—it will bear away the laurels in point of permanence, seeing that the alkaline and *sel d'or* baths tone the prints previous to their immersion in the strong hyposulphite bath; the consequence is, that the hyposulphite acts very keenly in the darkened parts, thinning their coating of gold, and, as a consequence, rendering them more apt to be acted on by the actinic rays than the prints which are toned by the old hypo. bath, seeing that the chloride is reduced as much as it possibly can be before the action of the gold commences, which action, being prolonged, gives a deeper coating, and renders it more able to withstand actinic action. I will now for a short time advert to part of the matter advanced by Mr. Stuart in his paper read at our last meeting. The first item made reference to the permanence of photographs toned by the alkaline bath, in contradistinction to the old system of toning; and he produced two prints of the same age, showing distinctly a yellowing of the whites, which I presume was not the case when they were first mounted. To have made the experiment complete, however, Mr. Stuart should have produced a print toned by each of the two baths, of the same age, and, if possible, with the understanding that the one was as carefully manipulated as the other. The next item Mr. Stuart made reference to as leading to failure seemed to me to be the laying of the albumenised sheet on the surface of the nitrate bath, in which he regretted the mode suggested by Thornthwaite, and advanced, as a better method, that of beginning at one end of the sheet and carefully letting it down until it came in contact with the solution. This we all admit. But further, continues Mr. Stuart, this must be done as carefully as inserting a collodionised plate into the bath, as a stoppage will leave a streak or wave over the whole sheet. Of this I am not so certain, although, had I not been bothered with this same twelve months ago, I certainly would have accepted Mr. Stuart's remark. But happening to have by me a print which I kept as an example of this wave line, as also of bronzing, I am led to form a different opinion; for, as in the example which I now produce, I cannot think I would stop some ten or twelve times before I had laid half-a-sheet of albumenised paper in the nitrate solution—which was not of the strength promulgated by Mr. Stuart, being only some sixty grains to the ounce, and consequently less liable to stain from careless manipulation. The bronzing also is very apparent. My opinion is, that such streaks (at least in this particular case) result from imperfect coagulation of the albumen. Some makers of albumenised paper do not seem to hot-press the sheets after they have been coated, but simply allow them to dry spontaneously, which drying, I contend, is not sufficient to properly coagulate the albumen. This we may reasonably infer from the amount of animal matter which enters into combination with the bath solution, or from the frothiness of the solution when we return it into the funnel for filtration. It seems to me, and perhaps you will find it to be the case on carefully watching the experiment, that after you have lifted your sheet from the bath, after dipping some ten or fifteen sheets, the solution in the bath begins to get a little reddened (which Mr. Stuart does not object to, but of which I cannot say the same, as I believe that reddening proceeds from a slight precipitate of sulphur) as also to get thickened. Now, from whence comes this reddening and thickening, but through the uncoagulated albumen entering into combination with the bath? The bath becoming saturated with it, will no longer take up the loose albumen from the succeeding sheet, but impart to it an albuminate of silver, which, first drying at the point where it is pinned up, goes on drying irregularly, and thickening as it goes down, leaving a residuum at every stage—hence the wave line and the streaking. This fact also applies to the bronzing, as I believe it to proceed from no other cause than a surfeit of albumen, in conjunction with nitrate of silver, or, what is worse, albumen in a slightly putrid state; and the more am I strengthened in my idea when I remember the fact stated by our President in his paper *On the Influence of Heat and Light in Changing the Physical Properties of Bodies.* There he pointed to an important result in regard to albumen used as a varnish in the state it came from the egg as destructive to the material of which the picture was composed: this he concludes, and I think correctly, to be due to the small quantity of phosphorous and sulphur existing in the albumen forming phosphate and sulphuret of the metal, both of which are subject to re-arrangement of the particles under the actinic rays. Now the albuminate of silver being acted on before, the chloride or the rays of light passing through it before arriving at the actual chloride produces, according to my notion, the bronzed appearance. This bronze I have often wished to wipe off that I might get the picture beneath. I do not mean to say that bronzing happens so in every case, but in this particular one it seems certain. The next item touched on was failure as arising from a mealy appearance in the prints. No solution was offered for this unhealthy phase, but it was stated that the mealiness could be observed in the printing-frame before the print was put into the bath. I have a small specimen of this phase of failure, or what I call mealiness; but perhaps it may not coincide with the mealy notions of others. As this same disease caused some keen discussion last evening, perhaps some of our friends present may have other phases of the same failure.

This failure seems to me to arise from the paper which is to be albumenised being of a porous nature, the pores absorbing a greater quantity of the albumen and salting, whilst the more even portions absorb a lesser quantity. On the sheets being subjected to pressure, those pores containing more of the albumen are compressed to a greater extent than the more level portions are, consequently more hardened and horny than the other. The sheet being placed on the silver solution, the softer parts of the albumen absorb a greater quantity of the silver than the horny parts; and if the sheet is quickly snatched from the bath, those more hardened parts not being thoroughly saturated, on being exposed to the light, are not so quickly reduced as the other parts, and here we are enabled to discover the mealiness even in the act of printing. I observe, especially when such prints are placed in the alkaline bath, that those parts which seem to be subjected to most pressure remain brown and horny like, whilst the intermediate spaces become quickly darkened.

With regard to the measles, or those hard gritty specks which mar an otherwise good print, I am not sufficiently familiar with their nature to offer an explanation why they occur; but I have observed that in some sheets of paper where the glaze did not appear so high as on the other parts, or where the paper was more bibulous, these (after the toning, especially in the old hypo. bath) gritty spots appeared in great number. I also believe that the more the salting solution is allowed to saturate the paper the greater the chance of producing this nauseous blemish, which a prolonged immersion in the strongest hypo. does not seem to move. I have not a specimen of this particular phase of failure, but it appears to me to be the formation of some double salt of sulphur in the body of the paper; for, on burning portions of such paper, I find a blue flame rises at the points where the gritty knots are—a crude experiment indicating the presence of sulphur.

Another phase of failure looms forth in the yellowing of the print. Perhaps this is as troublesome a phase as we have to encounter: it seems to be the most familiar in working with albumenised paper, as I have found it commence on immersing the print newly from the printing-frame into a bath of clean water. I have found the same taking place in the *sel d'or* bath, especially if I was pushing the print to a deep black: the whites turn to that annoying jaundice colour; and I have found the same ignoble colour rise in the print, after passing cleanly through the whole washing and toning process, on its immersion in the hypo. bath. Nor is it confined to the albumen paper alone; it peers out often on the plain paper. And even allowing that the print is beautiful from the beginning of the process until the end, having black purple shades, and clear, well-defined lights, is carefully mounted—for a photographer, when he gets a batch of prints through all the circumstances of washing, toning, and dressing, is very mindful of them till the whole operation is finished, which indeed gives him pleasure, as he feels that his labour has been rewarded—how perplexing is the fact that this same disease after a time returns, and that in the space of five or six years we find our darling subjects spoiled by an incurable attack of yellow fever! To the honour of the alkaline bath, be it said, I have found very few failures of this kind, so far as the toning is concerned; but there are difficulties attending the use of this bath also, as one sample of chloride of gold may be stronger than another, which happening often causes us to loose a good print, from a cold, blueish-black tint, or from the possibility of the alkaline dissolving or softening the albumen, raising blisters, at the back of which hyposulphite of silver gets lodged, which in the after-washing is difficult to clear away. Again, there is a series of secondary failures, resulting from the salting bath being stronger than the silver bath, and *vice versâ*, as also dirty spots arising from air bubbles getting between the surface of the solution and prints, or from prints in the toning or fixing baths lying too closely together; but those defects are more readily cured in comparison with those just enumerated.

I have now adverted in a rough way to what I consider some of the chief difficulties we have to encounter in the pursuit of our art, and tried to give an exposition as to the cause of some of them. I may not be correct in my notions in regard to those matters, but I am willing with others to lend my aid, however humble the effort, to have such cleared away. I may not be correct either in my conception of the remarks which came out in papers to which I have referred; but I am very willing, as I have already stated, to be corrected. When any notion of any particular theory seems false to us we should endeavour to eradicate that notion from the minds of others, or, if we are wrong, to have it properly understood by ourselves, thus fulfilling the end of mutual improvement.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

The members of this Society held their first meeting for the season at King's College, on Tuesday Evening, the 6th instant,—the Right Hon. Sir Frederick Pollock, the President, in the chair.

The President said he could not help congratulating the members of the Society who had met on the present occasion, that they were at length assembled under the roof of King's College, and that they were there with every prospect of success, and with a very great saving to their funds. They must be well aware of the expense they had been put to in hiring that out-of-the-way place in Leicester Square, which, although taken with every promise of success, had failed to prove attractive. To use the words of Milton—

"Here we may range secure."

He wished to express the great pleasure he had in meeting them, and in looking at the productions of M. Joubert, Herr Pretsch, and Mr. Thomas, which those gentlemen had so kindly presented to the Society. He thought few things were more beautiful. If they had cast their eyes over what was spread on the table, they must have seen there what spoke in far more eloquent language than he could employ—the beautiful photographs which had been presented to them that evening. Some of the specimens would be the subjects of papers to be read to them, and others would be explained by those who had done the Society the favour of introducing them there for the purpose of making them known, and he was sure the Society was under the greatest obligation to those gentlemen.

The following gentlemen were duly elected members of the Society:—John Scott, Esq., Russell Gordon, Esq., and W. Plumtre, Esq.

Dr. Diamond read a paper *On the Apparently Incorrect Perspective of Photographic Pictures Produced by Lenses of Different Focal Lengths, as Usually Viewed or Looked at, which may be Considered as a Kind of Apparent Distortion*, by Mr. J. Rothwell. [See page 327.]

A vote of thanks was given to Mr. J. Rothwell for his paper.

Mr. Shadbolt said he had a few observations to make upon the paper they had just heard, and he was sorry Dr. Diamond had omitted reading the mathematical portion of the paper, as upon that the question raised principally turned. He was glad that Mr. Rothwell had treated the question mathematically, instead of making use of the mere cant terms so frequently employed. He was glad to see in the chair one who was used to weigh words, and to ascertain their true meaning, whether used for the purposes either of explanation or mystification. He, however, did not charge Mr. Rothwell with having endeavoured to mystify the subject, On the contrary, he considered he had treated it in a very lucid manner. It had been said that "nothing was so false as facts, except figures;" but in his opinion it was not the facts or figures that were so often false as the deductions presumed to be based upon them. He found that several of the deductions drawn by Mr. Rothwell were open to controversy, and that there were several charges brought against photographs which were not reasonably founded. He (Mr. Rothwell) pointed out the cause of some kinds of distorted effects in photographs; but he did *not* state what was equally true—that precisely the same faults existed in pictures delineated by the hand of the most skilful artist, if viewed from a distance different from that maintained while producing them. He should endeavour to rescue photographs from some of the charges so made against them in particular, as they are shared in equally by all pictures. The facts detailed by Mr. Rothwell were indisputable; but he did dispute some of that gentleman's deductions. Mr. Rothwell stated that if pictures were taken by a lens of twelve inches focus they would probably appear correct in drawing; but that, if pictures were taken by lenses of shorter focus, they would be incorrect. Now he had said, and truly, that if a picture, taken by a lens with a focal length of twelve inches, were viewed at a distance of twenty-four or sixty inches, it would appear incorrect; and therefore, when he said that a picture, taken by a lens twelve inches in focal length, would appear correct, the assertion was true only if viewed at that distance. He did not acquiesce in the explanation which Mr. Rothwell had attempted to give, relative to the apparent enlargement of near over distant objects. In his (Mr. Shadbolt's) opinion that was owing to the altered *power* of the lens. On bringing an object nearer to the lens than the general area of the picture being delineated, a readjustment of the focus of the lens was necessitated, whereby the power of the lens was interfered with, and the object was delineated comparatively larger than the rest of the subject. Mr. Rothwell had attempted another explanation—the alleged fact that two poles, at a distance of ten and forty yards respectively, did not appear distorted when viewed by the eye, because the eye was naturally adjusted to each when looking at them. The single eye, however, could not be adjusted in a manner to judge of distance, both eyes being required for this purpose. If the two eyes were brought to bear on one object, and then shifted to a more distant one, there was a certain movement in the inclination of the axis of the eyes which by experience enabled the spectator to judge the proportional distance of the object from him. If the eyes were adjusted first upon a distant object and then upon a near one, a convergence of their axis would take place, and a movement would be perceptible, even although the objects were in the same line; but if one

eye were shut, and the two objects were alternately looked at, there would be no movement of the eye perceptible, and both objects would appear equally distinct, provided they were in the same line from the spectator. The size of the object was judged of by that of the angle subtended, together with the distance of the spectator from the object. Thus few people except astronomers were acquainted with the real difference in size between the sun and the moon, because those bodies were placed at such a distance that the convergence of the axis of the eyes in looking at either was as nothing. Even in looking at a familiar object the spectator could not form a correct idea of its size until he had brought both eyes to bear upon it. If he saw a man approaching from a long distance, even with both eyes, he would not be able to say whether he was a short or a tall man until he came near him, because the convergence of the axis of his eyes would be so small that he would be unable to judge of his distance, and hence would not know the value of the subtending angle. Therefore, it seemed to him that the alleged apparent disproportion between the two poles, as seen in the picture, arose simply from the fact that two eyes were used to look at it; and hence the fact was revealed that both images were at the same distance from the observer; but if one eye only were employed at the right spot, all the proper perspective would be restored. He thought artists were instinctively conscious of that fact, for frequently in viewing pictures they made use of a small instrument by which they prevented one eye seeing them at all. Mr. Rothwell again asserted that the near objects of a subject were usually in the margin of the picture. That proposition he denied *in toto*. In taking a landscape it was generally necessary that the lens of the camera should be raised above its normal position, for the purpose of taking in more sky and excluding the useless foreground. That proposition of Mr. Rothwell's therefore fell to the ground.

The next point to which he would draw their attention was the remark Mr. Rothwell had made relative to the distortion in portraits. It appeared to him (Mr. Shadbolt) that Mr. Rothwell was charging to other errors that which was due simply to the bad selection of the point of view. In taking the portrait of a sitter, a point of view should be taken up by which the whole of his person could be included; but if the camera were pushed up to within two or three feet of him, the nearer features would entirely eclipse those which he might call the background features. Thus, if the camera were pushed nearer still, the ears would be entirely hidden by the cheeks. Therefore, when Mr. Rothwell said that a lens of too short a focus produced this kind of distortion, he meant if it were brought too near the object. In the next place Mr. Rothwell spoke of the enlargement of objects out of the focus. To that expression he demurred, as he contended there would be no *material* enlargement, so long as the object were at all defined, but merely a blurring—a thickening of the lines, as if copied on blotting-paper. Mr. Rothwell next proceeded to mention the distortion produced by viewing an object obliquely. "Cocking" the camera was the special point to which he drew attention—that was turning the camera so that it leant upwards to an object. Although he (Mr. Shadbolt) admitted that pictures delineated in that way looked distorted, yet he contended that, if viewed in the proper manner, they were not so in fact. If one stood near a building—Westminster Abbey for instance—and looked up, a certain picture was depicted upon the retina, the nearest equivalent to which would be a plane held up between the eye and the object at right angles to the axis of the eye, and if the picture as seen by the eye were drawn upon it, it would appear distorted if viewed in any other position. Mr. Russell Sedgefield had sent him a stereograph (which he exhibited) that appeared, when viewed in the ordinary way, to have a hideous amount of distortion, but in a paper which Mr. Sedgefield published in The British Journal of Photography some months ago, he pointed out the fact that, if in viewing that picture in the stereoscope the spectator turned it up to the sky as if he were looking up at the building, he would immediately perceive that the distortion disappeared. If there were a stereoscope in the room the members present might perceive that it was exactly like looking at the subject in nature. He had left to the last a remark which really ought to have come first. He found it stated that the paper was by Mr. J. Rothwell, "inventor of the method of constructing photographic lenses free from distortion." He regretted exceedingly that Mr. Rothwell was not present, as he should have been glad to have been informed by him what particular point he claimed as his invention. The only reference to the subject was made at the close of the first portion of the paper, in which he spoke of *his* principle as explained in a paper read before this Society. He did not recollect any principle which had been laid before the Society that could be truly claimed as novel in producing lenses free from distortion. At the time that the paper to which Mr. Rothwell alluded was read, he (Mr. Shadbolt) pointed out the fact that, from the earliest days of photography—apart from daguerreotypes—being first practised in this country, lenses had been constructed upon the same principle as that indicated in the paper. He presumed that Mr. Rothwell claimed the insertion of the diaphragm between the lenses. But he thought he was in a position to prove that that was not invented by Mr. Rothwell, but by a gentleman at Liverpool, who worked with Mr. Robert Hunt in the earlier days of daguerreotype. Moreover, in 1851, he had the pleasure of seeing in Dr. Diamond's possession, or in the possession of a friend of his, one of Archer's arrangements which had that peculiarity.

Dr. Diamond said a friend of his had that lens at the present time.

Mr. Shadbolt continued.—Before the earlier date to which he alluded, he believed double combination lenses were scarcely in use, and in all made by Mr. Archer he did not think that diaphragms were ever placed in any other position. It was well known to every practical optician that when so placed distortion of the marginal lines was avoided. But if Mr. Rothwell claimed to have originated the notion suggested by Mr. Sutton, that it was necessary that the back and front combinations should be identical in form, to prevent distortion, he was ready to dispute it. Before he sat down he could only say that he was obliged to Mr. Rothwell for laying before the Society a lucid explanation of certain facts that most persons had observed, but that few had been able to fix an exact value upon.

The President said he was quite sure that he should be permitted to say that they were very much obliged to Mr. Shadbolt for the information he had given them. He, however, was not quite so certain as Mr. Shadbolt was that the single eye did not alter its focus in viewing objects placed at different distances; for he recollected the exhibitions that used to take place of the phantasmagoria, in which, upon the same plane, the shadow of an object was thrown. The image of it was made to start apparently from a great distance, and to advance until it appeared to be close upon the spectators. That effect was produced not by the motion of the plane upon which the image was formed, but by altering the focus, and, at the same time, to change the position of the instrument used for producing the image, in order to keep the latter distinct; and it was only by this double motion that change of size and distinctness could be given to the image. He did not feel competent to give any definite opinion; but he believed most philosophers considered that the single eye, in looking at a distant object, adapted itself to the distance exactly as a telescope was pulled in or pulled out when used for the purpose of looking at objects at various distances. In the same way, when looking through an opera-glass at a person in the next box, the glass must be differently adapted to what would be required when looking at a person at the further end of the stage. This was perfectly familiar to all who used spectacles; and for his own part, although he could see well enough the paper before him, he could not, without the aid of his concave glasses, recognise a friend at the end of the room. There were persons who were able to adapt one eye so as to see an object at a great distance as well as one near; others had more limited powers of vision, and were able to see near objects, but were unable to see objects at a distance. With all due deference to Mr. Shadbolt, he did not agree with his explanation on this point. He recollected having seen several ingenious specimens of pictures drawn upon a plane in a distorted manner, which, when regarded from a certain point of view, acquired a natural appearance. There was one instance he recollected of a castle and a tree and some other objects being delineated upon a plane in a distorted manner, and if it were looked at from a particular point all the objects appeared to rise up, and the castle and the tree took their proper form. There was another still more extraordinary instance, where a human face was spread out and twisted in a most extravagant manner; but on looking at its reflection in a glass of a certain shape, all deformity vanished, and it became the face of some well-known person. All those instances were well known to those who studied optics. He knew enough of optics to be aware that the image of a straight line became a conic section in certain cases, or a part of a circle, or a part of an ellipse, just the same as the shadow of the top of a lamp if thrown upon a wall sometimes assumed the form of a hyperbola, or that a circle became a porabola under some circumstances. Those distortions were common in all cases where images were formed either by lenses or by reflecting glasses; and probably the best instance of the distortions which arose in photography was the image reflected in the camera-obscura upon a flat and not upon a concave surface. There, as in photography, the centre was perfect, but the surrounding margins were distorted; and in order to make the camera-obscura an instrument of instruction and amusement, the image was received on a concave surface, whereby the edges were rendered distinct, and a decent picture was obtained. He might add, with the greatest deference to the opinion of Mr. Shadbolt, and with many thanks to him, that he had endeavoured to show that some of the observations of Mr. Rothwell might not be so entirely out of place as they might appear to Mr. Shadbolt.

Mr. Davis said he had a few words to say upon the question of the enlargement of the picture towards the margin. Mr. Shadbolt considered there was only a blurring, and that there was no enlargement. He, on the contrary, thought there was an enlargement; for, presuming they had a plane upon which the picture could be delineated, the lateral lines would become an arch, clearly showing that the edges were somewhat enlarged. The second point he would refer to was with regard to the appearance of distortion produced by turning the camera obliquely to an object on bringing it to within a short distance of it. He thought if he got near to an object, according to correct perspective, that the upper part of two lines forming the sides of a high building *ought* to appear to approach each other. If a person measured the apparent width of the base of a tower, and compared it with the apparent width of the top, he would find the top much less than the base. The lines appeared to converge at the top to the eye the same as they did in the photograph.

The President said, in confirmation of what had fallen from Mr. Davis, he must say that it was impossible to doubt that if a spectator stood in the middle of a plane, with four lines rising perpendicularly from the

north, south, east, and west, and were conceived to be of infinite length, they must actually meet in the centre of the heavens over his head. There could be no doubt upon that point to a philosophical mind. At an infinite distance the interval between any two of the lines must be comparatively nothing—the consequence of which was that they must appear to meet.

Mr. Bull said he could not help thinking that Mr. Shadbolt was wrong in saying that the single eye could not appreciate distance, for he could not see the back and front sight of his rifle with one eye at the same time, and to see them distinctly he had to alter the focus of his eye backwards and forwards.

Mr. Shadbolt asked permission to say a word or two in explanation. A slight error had been made in attributing to him the assertion that the single eye made no adjustment when looking at a near after a distant object. What he did say was, that the spectator was not conscious of the adjustment. He admitted that the eye might make an adjustment for focus, but he denied that it made any that would assist in judging of distance. Therefore it was impossible that the single eye could give a true idea of relative distance.

The President said, "Then God help the one-eyed people!"

Mr. Shadbolt said he thought it would be found that all one-eyed people moved their heads from side to side, and thus obtained the value of the subtending angle by displacement of position. A very old illustration of this fact—for it was a fact, capable of proof—was to blindfold one eye of a person, and then to let him try to snuff a candle placed at an uncertain distance before him. Nine times out of ten he failed in doing so, being deprived of the means of judging of the correct distance between himself and the candle. There were two other points to which he wished to call their attention. Sir Frederick had remarked that perpendicular lines drawn from the four quarters of the compass must meet in the heavens. Now that point he disputed.

The President said they must meet if they were visible, and were prolonged indefinitely.

Mr. Shadbolt said there was a proposition in Euclid which was indisputable, namely, that parallel lines, however much prolonged, never could meet.

The President said it was a question of appearing to meet. At an infinite distance one hundred miles would appear as a mere point. Supposing the four poles which were thus to be extended were five hundred miles distant from each other, when they had got to about the distance of the moon from the earth their points would appear to meet, or would be so near together that it would require a very powerful telescope to distinguish them. Mr. Shadbolt was imputing to him that he meant that they met in fact, but what he really did say was that they would appear in perspective to meet.

Mr. Shadbolt said that if the poles were visible at the distance supposed *the space between them, being so much greater, must be even more visible.*

The President said that these purely scientific questions were hardly worth discussion.

Mr. Shadbolt said then he would refer to the remark by Mr. Davis, that when looking at a distant object, it subtended a much smaller angle than when the eye was directed to it when near. He perfectly concurred in that; but Mr. Davis forgot that at the same time the angle would be the same on looking at the plane of delineation, if interposed *parallel to the object delineated*, producing the same effect to the eye as if the object itself were looked at, and the subtending angle would be the same. If the paper of Mr. Rothwell were carefully read, it would be found to prove that proposition distinctly.

Mr. Davis said that it was impossible to place a plane of delineation parallel to the object, unless the plane was equal in size to the object to be delineated.

Mr. Shadbolt said that was an error, as Mr. Davis must perceive on reflection.

Mr. Davis said that it was quite true, as Mr. Shadbolt observed, that parallel lines did not meet, however prolonged; but the sides of a road certainly presented the appearance of converging.

Mr. Malone said there was a photograph of a railway bridge which had been presented to them, wherein the four sides of the entrance occupied the whole of the sheet of paper, whereas the far end was a *small white spot* in the centre—the distant sky being shown clearly through the whole length of the tube. It was there clear that the whole distance, upwards of two miles, was represented by the convergence of the lines towards the centre of the picture. If Mr. Shadbolt were to look at that bridge through a piece of gummed glass, he would perceive the same effect in nature, and he would see that the lines appear to meet to his eye in a small point. Supposing he looked up through a perpendicular tube, instead of through a horizontal one, the apparent convergence would be the same.

Mr. Heath said the other day he was detained at a railway station in the country, and he had an opportunity of noting the effect of the convergence of the rails on a peculiarly straight line. At both ends they appeared to meet. He did not think that what was in nature, and in accordance with natural vision and perspective, ought to be considered distortion in photography.

Mr. Hughes said Mr. Heath had met the real question. It was very strange that they should now have to discuss the first principles of perspective. Things were called distortion in photography which, if severely tested by the rules of perspective, would be found to be correct. In order to correct such apparent distortion, Mr. Rothwell stated that in viewing a picture the eye must be placed at the point at which it was supposed to be when the picture was delineated. Supposing they took a portrait, and, by placing the lens near the sitter, obtained a figure with prodigiously large feet and with a comparatively small head, if they placed the eye in the same position all disproportion disappeared. However, although it might be scientifically correct, the distortion was very offensive. Of course his remarks would not apply where the distortion arose from a defect in the lens itself. The tendency of a short focus lens, when used to cover too large a surface, was to exaggerate the apparent distance between near and distant objects, so that near objects were comparatively larger than the rest of the picture. As a rule, photographers were apt to employ too short focus lenses. They tried to obtain a half-plate picture with a quarter-plate lens, and a whole-plate picture with a half-plate lens; whereas they should do exactly the reverse, and take half-plate pictures with whole-plate lenses, and quarter-plate pictures with half-plate lenses. With regard to one remark made by Mr. Shadbolt, he wished to say that he did not know who had introduced central diaphragms, but he knew that they were used prior to 1850, as he had used one himself originally, and he had an old American journal, dated before that time, in which central diaphragms were mentioned.

Mr. Malone said he thought there must be some misunderstanding on one point, and he thought it only fair to Mr. Shadbolt to ask him whether he disputed the apparent convergence of perpendicular lines. It was so elementary a point, that he was sure he would not dispute it. With respect to another point made by Mr. Hughes, he begged to say that M. Claudet had been for a long time impressing upon his pupils the necessity of using long focus lenses. Although the apparent distortion of the picture might be defended by the rules of geometry, it could not be defended by the rules of that which ought to govern them—the rules of good taste. Mr. Collen had refused to take a loft door some distance above the ground, stating that, as he could not produce a good picture from it, it was better not to take it at all. There was a question he had frequently asked photographers and artists, without obtaining an answer, which was—What description of lens ought to be used, and what distance and angle the lens ought to be placed from the object, to produce a satisfactory result? It appeared to him that they were left entirely to hazard upon those points. Some accord ought to be come to between the rules of perspective and the power of photographic lenses. He had seen a most hideous caricature of the maker of certain lenses, which was exhibited for the purpose of showing how large a picture the lens would take.

Mr. Shadbolt said that he thought nearly every observation upon what he had said had been made under a misconception. The proposition he started with was, that if a picture were required to be delineated correctly, *the plane of delineation* ought to be *parallel* to the object delineated. If he looked up at a tower, its sides would appear to converge; but if his plane of delineation were interposed *parallel to the tower*, the lines drawn from the eye to the marginal lines of the tower would cut the plane of delineation by lines which do *not* converge, but which would be parallel as in the tower itself. He would reply to Mr. Malone's observation relative to the tubular railway bridge, by pointing out that in that case the plane of delineation was at *right angles* to the apparently converging lines, and, therefore, it did not apply to his (Mr. Shadbolt's) remarks; but even in that case, as bearing upon the President's supposition of the four poles meeting overhead, although at a distance of *two miles* the angles did *not appear to meet*, there was still the small white spot, although the lines of the angles themselves had disappeared.

Dr. Diamond then read a letter from Mr. Dallmeyer, enclosing some specimens. He had also to announce communications from Mr. Thomas and Herr Paul Pretsch, explaining some of the specimens on the table.

The President said that he held in his hand a specimen of the actual work of light upon copper. It was not exactly an original invention, but it was a great improvement on the former process, as the picture presented the appearance of having been worked on by an engraver, although Mr. Pretsch gave his word that such was not the fact, but that it was entirely the effect of photography. Thus copies of that picture could be produced in great numbers, at a trifling expense. M. Joubert had produced photographs fixed upon glass, and Mr. Barnes exhibited his enamelled photographs. Mr. Malone also exhibited specimens of pictures printed by electric light. [The various specimens alluded to were handed round to the members.]

Mr. Malone said he was happy to lay before the Society the pictures he had produced by electric light, as it might be of great use under certain circumstances. He had often experienced great difficulty in printing in the winter, and having turned his attention to electric light, he found that he could print from a negative in a quarter of an hour, by simply exposing it to the light produced by carbon points. He found that it answered better than the natural light on a dull day. Thus good effects might be produced at any time of the day or night. He had used one of Duboscq's lamps, belonging to Mr. De la Rue. He thought he had shown that electric light was superior to atmospherically-deteriorated sunlight. It was no doubt expensive, but still, under certain circumstances, people would not mind the extra expense. With respect to M. Niépce de St. Victor's alleged discovery of bottled light, he considered that the effects produced were owing entirely to the vapour of the ink used by the French in printing their newspapers. He had found by experiment that, without

any application of so-called bottled light, a French newspaper would leave its print on sensitised paper, whereas the heading of *The Times* made no impression at all. He had not exposed the paper to the light at all, the whole operation having been performed in the dark. He had thus deprived M. Niepce de St. Victor of the power of bringing against him the same charge he had against Mr. Busk, namely, that he had exposed the engravings to the light previously to commencing the experiment. He thought the effect was caused by the vapour of the printing ink suspending the action of the chloride of silver.

A Member asked whether a negative or a positive had been obtained.

Mr. Malone said he at first thought he had obtained a positive, but he subsequently found that that appearance was caused by the transparency of the paper, and that in reality it was a negative. On the back, however, was a very distinct positive.

A vote of thanks to Mr. Malone was then passed.

Mr. Heath said he knew the trouble and expense of Duboscq's lamp, and he should be sorry that it should go forth that it could be cheaply and usefully applied for photographic printing.

Mr. Malone said he had mentioned the expense. The light cost about 10s. 6d. for half an hour. But still good effects were produced by it, which, under certain circumstances, would entirely counterbalance the expense.

The President said he had to present to the Society, as coming from Mr. Silmer, a beautiful specimen of the application of photography to the reproduction of old manuscripts.

Votes of thanks were then passed to Messrs. Dallmeyer, Joubert, and Pretsch, for their specimens and papers.

The President announced that the next meeting of the London Photographic Society would take place on the first Tuesday in December.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of this Society was held on Wednesday evening, the 31st ult., at Myddleton Hall, Islington,—George Shadbolt, Esq., V.P., in the chair.

Mr. John Barnett, Hon. Sec., having read the minutes of the last meeting, which were confirmed, the ballot for new members took place, when Mr. George White was declared duly elected a member of the Society.

Mr. D. W. Hill, Hon. Treasurer, read a paper, entitled *A Photographer's Holiday in Derbyshire.* He also exhibited a number of fine stereographs of Derbyshire scenery. [We are at the last moment obliged to withdraw Mr. Hill's interesting paper. It will appear on Dec. 1st.]

The thanks of the meeting were tendered to Mr. Hill for his paper.

The Chairman said there was then a nice little opening for a discussion upon dark tents and boxes; and if any one had visited the places described by Mr. Hill, there might also be a useful discussion got up upon the best points of view from which to take the photographs. He had had an opportunity of inspecting those exhibited by Mr. Hill, and he had been particularly struck by one of them—the *Stone Staircase leading to Haddon Hall*—which was one of the best of that place he had ever seen. It came out beautifully in the stereoscope. There must have been some difficulty in getting the avenue of yew trees so successfully.

Mr. Hill observed that he had been to Wingfield Manor, which appeared to him to be a very beautiful spot, and which would have been fifty times more beautiful if the hill had not been completely obscured by the rain and mist.

The Chairman: There is one point which I think might be advantageously considered, namely, whether it is desirable to make use of the dark box partially as a camera, or to have a dark tent and to use the camera separately. It has been thought by some that the internal space of the camera might be used for the purpose of manipulating plates in; but they had forgotten one material point, which was, that it very rarely happened that the camera was dropped down at once on the exact spot from which the photograph was eventually taken; and if the camera and tent were together, a large amount of material would have to be shifted about.

Mr. Hill said if his camera and tent had not been separate he could not have worked, in consequence of the heat of the sun. He could assure them it was no joke working in a small box during hot weather.

The Chairman asked whether Mr. Dawson had had any experience in the use of dark tents out of doors.

Mr. G. Dawson replied that he had made some little use of it. About five years ago he had some experience with one of Archer's cameras, which they had doubtless seen. He, however, never could see comfortably the progress of the development through the yellow glass. On one point he had come to a decided opinion—namely, that the larger the tent the better it was. The best he had seen was Smartt's, which was larger than Archer's, and was easily carried. In that he performed operations easily that were almost impossible in a small one; as, when working in the latter, it was absolutely necessary to go out for air after a short time. If uniformly good results were desired, it was necessary to have a large tent, which, however, did not at all mean a heavy one. Some tents were made to carry a number of heavy bottles, which was quite unnecessary, as it was not requisite to wash the plates at the time; for, if a strong solution of hyposulphite was poured on, it would do all that was wanted at the time. Some beautiful results had been obtained by Mr. Ross, of Edinburgh. He operated in a tent about three feet high—at least, he had a little hunch-backed boy who crawled in and developed the plates. He himself preferred to keep outside; but he said he should certainly have a large tent—one that a man could breathe in—one that three or four persons could stand in in case of a shower of rain. He had been able to take a picture sometimes in five minutes after commencing to set up his tent. Most people objected to large tents; but he preferred them, especially in cold weather, as the collodion then worked better in a large tent than in a small one.

Mr. Hill said that with Rouch's box the operator escaped the vapour of the chemicals; and this, in his opinion, was a great advantage, especially to persons in ill-health.

The Chairman handed round several stereographs of the scenery around Beddgelert, North Wales, from collodio-albumen negatives, taken by Mr. Morris Beck.

Mr. Maltwood then exhibited a portable operating-box of novel construction, weighing from eighteen to twenty pounds. The box itself forms the stand for the camera, which, by an ingenious arrangement, can be made to slide from side to side, and to revolve without being unfixed from its stand, the base of which is much more extended than that of the ordinary tripod-stand, and supports the box with great steadiness. Attached to the box is a portable flexible cistern, which holds sufficient water for several hours' work. The bath is placed in a corner, so that no mistake can be made. From the manner in which it folds, and the arrangement of the straps, any objection against it on the score of weight is removed, and it can easily be carried for miles.

The Chairman then called the attention of the members to the large composition photograph on the table, called *The Holiday in the Wood*, by Mr. Henry P. Robinson, of Leamington, which he (the Chairman) had the pleasure of exhibiting.

Mr. Simpson exhibited some of Mr. Skaife's chromo-crystal photographs for bracelets, brooches, &c.

The Chairman said Mr. Skaife prided himself upon being able to take those pictures with his pistolgraph without the knowledge or consent of the involuntary and unconscious sitter.

Mr. Simpson having stated that Mr. Skaife had promised to attend their next meeting to produce and explain his pistol camera, then proceeded to exhibit and explain Meagher's improved portable camera.

Mr. Hill said he was sorry Mr. Morley was not present, as he had invented a portable mount for the lens, whereby all screwing was avoided.

Mr. Simpson observed that the mount consisted of a cell into which lenses of various focal lengths could be dropped. The brass mount was always kept on the camera ready for use, and the necessity for a rack and pinion dispensed with, as all the focussing was done from the back of the camera.

Mr. Hughes asked how the hood was provided for?

Mr. Simpson said there was no hood at all. It had brass stops, and the lens was chiefly inside the camera. Mr. Morley would shortly show them his invention.

Mr. Hughes remarked that some person—he did not know who it was—had taken out a patent for a new mode of mounting lenses. He did not know that it was in the market, as he had not seen it for sale. The mounting was for a single lens, and its peculiarity consisted in its being a series of rings put together on the principle of a telescope—in fact, on much the same principle as the bellows body of Mr. Meagher's camera. He thought at first that that invention was the same as Mr. Morley's.

The Chairman having been requested to ask Mr. Morris Beck to give them some account of his proceedings in taking the Welsh views,

Mr. Morris Beck said there was nothing new in the way he had proceeded. The pictures were taken by the old collodion process with Keene's collodion. Until this year Keene's collodion had never failed him, but it had done so this year in some instances, as he found that the two edges where the collodion was poured off had peeled.

Mr. Shave observed that he had found the same fault with Keene's collodion when using it in the Fothergill process, and he thought it was occasioned by its being thicker than ordinary.

Mr. Beck said that in some instances when the plate was drying after the second washing, the collodion had completely peeled off. He covered some of the plates with albumen, and the edges where the peeling commenced with albumen or copal varnish, both of which answered the purpose. So far as stains went, he did not think he had a single stain in any plate which he could attribute to the process. The great difficulty, so far as he could make out was, that the lights were apt to be too light—of a snowy whiteness—if the development were carried sufficiently far so as to get a strong negative.

Mr. Hughes said they had an element in the dry process which they had not in the wet—which was albumen; and, if sufficient care was not taken, they would most assuredly have their lights too hard. Any person who had seen the dry process must have been struck with the fact that a very thin negative would produce a very brilliant picture. The fact was that nearly every person who adopted the dry process went in for quickness, and the consequence was that their deep shadows were not well done. With the collodio-albumen process it was a good plan to expose for the shadows and leave the lights to take care of themselves, as it was almost impossible to over-expose with this process. He should like to know if any one had tried the effect of various proportions of water with the albumen.

The CHAIRMAN said he had tried every possible quantity between one thirty-second part and pure albumen, and the result in his mind was that, provided there was sufficient albumen to combine with all the free nitrate of silver which was left upon the plate, the result would be satisfactory. Mr. Hughes's observations really were to the effect that where albumen was used a much less intense-looking plate was obtained, and was necessary, than where collodion alone was used.

A vote of thanks was unanimously accorded to the exhibitors.

Mr. SIMPSON then exhibited some photo-lithographs.

Mr. HILL exhibited a positive on arrowroot paper, which, although rather cold in tone, was otherwise very satisfactory.

After the usual vote of thanks to the chairman, the meeting separated

MANCHESTER PHOTOGRAPHIC SOCIETY.

A MEETING of the above Society was held in the rooms of the Literary and Philosophical Society, 36, George Street, on Wednesday, the 7th instant,—Professor Williamson in the chair.

Mr. Henry Miller, Mr. Richard Guest, Mr. George Nelson, jun., and Mr. Rogerson, were unanimously elected members of the Society.

Mr. Sidebotham presented two beautiful prints to the Society from negatives, fifteen by twelve, taken by the collodio-albumen process; and Mr. Wardley a print from his admired negative, *Manchester from Victoria Bridge.*

Mr. NEVILL laid upon the table several pictures presented to the Society by Mr. Dallmeyer, and read the following explanatory letter :—

19, Bloomsbury Street, W.C., 5th November, 1860.

SIR,—It may, perhaps, be of some interest to the members of your Society, to inspect a few of the prints taken with my new "Triple Achromatic Lens," more especially since one of your townsmen, Mr. J. Rothwell, was the first who drew my attention to the subject of "distortion," as produced by the various forms of lenses hitherto employed for the photographic art, namely, the ordinary single combination view lens, and that of later-date invented by Professor Petzval, and sold under the names of Orthographic, Orthoscopic, &c., Lenses. The character of distortion, as appertaining to each group, is now well known to every lover of the art.

My portrait combination, in which I at first introduced the principle of freedom from distortion, has been received with favour by the public at large, and is extensively used for views up to pictures 10 by 8; but when required for larger sized plates it necessarily becomes expensive, on account of the large diameter of glasses involved in its manufacture, hence I was requested on all sides to construct a lens "free from distortion," more especially designed for views and copying, for larger sized plates.

After a series of protracted investigations, experiments, &c., extending over several months past, I have arrived at a form of lens which produced the results submitted to you this evening; and I will now state a few of the particulars respecting the instrument with which the pictures were taken. It has a focal length of about 18 inches, and consists, as its name implies, of three achromatic combinations. The front and back are "positive,"—the former $2\frac{3}{8}$in., the latter $3\frac{1}{4}$ in. diameter; between the two is situated an achromatic "negative" combination of $1\frac{1}{2}$ in. diameter. Each of the three has its contact surfaces cemented with Canada balsam, and the total number of "reflecting" surfaces, therefore, does not exceed those of the portrait lens. The negative combination is of such form and focal power as is required for the correction of both the central and eccentrical pencils, and with full aperture the lens is free from spherical and chromatic aberrations, both at the centre and margin of the picture, and the field is flat.

With the whole aperture ($1\frac{1}{2}$ in., or rather $1\frac{3}{4}$ in., for the pencils of rays are convergent upon the negative combination) the lens covers a plate 10 by 8 equally illuminated to the corners, and with this aperture the portrait of "Rifleman" was taken.

With 1 in. aperture the lens covers a plate 12 by 12 to the corners, and with this the views of "Interiors" of Winchester Cathedral were taken.

The maps were copied with $\frac{1}{2}$ in. stop; they are a little less than twice the originals. The negatives from which the prints were taken exhibit much more detail, but I was afraid to trust them into the hands of railway porters.

The view on plate 15 by 12 was taken with $\frac{5}{8}$ in. aperture. The lens and camera were very much tilted.

When the negative combination is removed, the focal length of the lens is reduced to about 8 in., and will take portraits in the same time as the ordinary half-plate lens: the chemical and visual foci coincide, but the field is not so flat as that of my portrait lens.

It is needless for me to offer any remarks in regard to the performance of the lens, since the results speak for themselves; and if they should be approved of by the members of your Society, and establish the fact that photographers can now possess themselves of an instrument which reproduces the objects of nature and art with perfect truthfulness, and is otherwise generally useful, I shall consider my time and labour well spent.

The pictures were taken by Mr. Downes, of the firm of Cundall and Downes, who kindly devoted some time to the testing of my lens.—I am, sir, yours, &c.,

J. H. DALLMEYER.

Mr. WARDLEY: I have anxiously looked for some time for such an improvement as Mr. Dallmeyer's lens appears to afford. This picture of the *Interior of Winchester Cathedral* is a severe test, and the lines of the columns are, I perceive, absolutely straight. They are slightly convergent, and that is all. In this picture of the cross that fault is seen to a greater extent; but it is evident that the camera, as Mr. Dallmeyer states, must have been much tilted, and with other lenses the lines would have been distorted to a far greater extent. In the copy of the map the lines are absolutely square and straight.

Mr. HOOPER: Many lenses which give bad results as regards the straightness of the lines may be improved by shortening the distance between the stop and the lens. I have found that Grubb's lenses are comparatively free from distortion.

Mr. WARDLEY: That does not agree with my experience. I have found them defective in that respect. In reference to the situation of the stop, you may cure distortion by bringing it near; but then you partially destroy the definition.

Mr. PYNE: It does not appear from Mr. Dallmeyer's letter that Mr. Rothwell was the *designer* of this arrangement, but that he had only suggested that something should be done to cure the distortion so common to lenses. I may, I believe, state confidently that Mr. Rothwell originally supplied the diagrams for the combination.

Mr. NEVILL: That is, I think, unintentional on Mr. Dallmeyer's part; for here is a printed paper on the subject, which was read last June before the members of the London Society, in which Mr. Dallmeyer says:—"To Mr. Rothwell belongs the credit of first suggesting the remedy, and to Mr. Sutton of bringing it before the public." I think that should satisfy the objection.

Mr. HOOPER: The time occupied in taking these pictures is not mentioned, and we cannot, therefore, judge of the quickness of the lens.

Mr. WARDLEY: I do not consider that important. The first thing to be considered is good results.

A vote of thanks was then passed to Mr. Dallmeyer.

The CHAIRMAN: I think that all particulars connected with the production of these pictures, and of all others presented to the Society's portfolio, should be written upon them. It is impossible to imagine the interest that may attend such information at a future period: whether the prints may last for one hundred years or for twenty years, changes may have taken place in the art which will render its history incomplete, unless the photographers of that day are able to avail themselves of such information as that which I now propose you should secure for their use; and I would, therefore, impress it upon you to make it a rule that no opportunity should be lost of storing up materials for those who may see photography in a very different position.

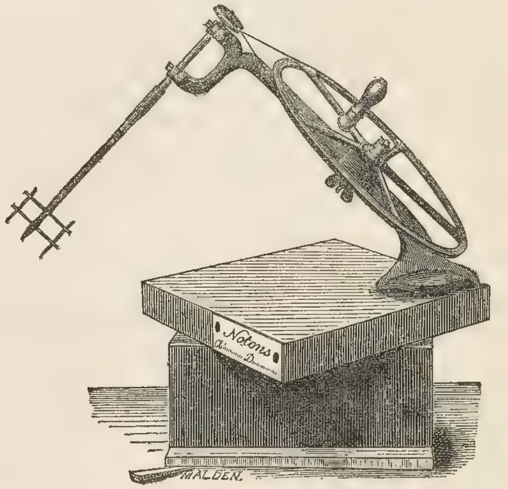
Mr. MABLEY: I have been requested by Mr. Petschler, whose modesty is only exceeded by his ingenuity in photography, to lay before you the results of some experiments he has lately made. These results, as you will see, are very imperfect; but I have advised him to secure the assistance of his brother members by at once making the thing known. I think that the aim being so great, it deserves investigation. Here are some negatives, the plates of which were prepared as for collodio-albumen, the whole of the free nitrate of silver from the last silver bath having been decomposed by a chloride. Upon one-half of this plate was poured a weak solution of chloride of gold, and the exposure in the camera (for twenty seconds) took place about three hours afterwards, with a stereo lens, one-quarter inch aperture. You will perceive that on the half treated with gold there is a picture of full exposure; on the other half not a trace of development. The picture is certainly very foggy, but there it is, and if some means be found of preventing the fog, we have perhaps the key to a quick dry process; but the question at present certainly appears to be full of difficulty.

After some remarks by Mr. HOOPER and Mr. MABLEY respecting the cause of fogging,

Mr. WARDLEY asked Mr. Petschler what prompted him to make the experiment?

Mr. PETSCHLER: I was printing on a dull day, and tried to finish the printing by development. Upon one of the pieces of paper some solution of gold had been splashed, and on those parts the picture started out with great rapidity when treated with gallic acid, while the lights remained pure.

Mr. NOTON and Mr. HEYWOOD exhibited machines for beating up albumen—that of the former gentleman being his own invention, and the first apparatus made known, we believe, for the purpose. Mr. Heywood's was purchased. The distinguishing feature of these machines is simply this:—In Mr. Noton's "albumen disentegrator," as that gentleman styles his apparatus, of which we give the annexed diagram, an



open work beater is caused to revolve rapidly by means of two pulleys, the one of much larger diameter than the other; in Mr. Heywood's there is a compound beater, the one revolving within the other, and in an opposite direction. This is accomplished by a face-toothed wheel which drives two pinions from opposite sides of the centre of motion. The albumen of six

eggs was measured to each competitor, and a performance began which at any rate gave rise to considerable amusement. Mr. Noton was satisfied with the operation in five minutes; but Mr. Heywood, in a minute less, produced a result which was pronounced fully equal to that of his rival. It was remarked, however, that, if the albumen were sufficiently beaten up, Mr. Heywood appeared to be sufficiently used up; and as no one could discover any material difference in the result, the saving of time and the relative prices of the machines were the only considerations; the former of these was too trifling to carry much weight, especially as it was only to be gained by a considerable excess of physical labour. Mr. Noton's apparatus is much more costly; but it must be stated that it has the advantage of greater simplicity, and that its higher price is mainly due to superior workmanship.

Mr. Pegg exhibited six negatives, taken on plates prepared by coagulating the albumen in hot water, according to Mr. Parry's process. One of these negatives was weaker at one side than at the other, by reason, apparently, of the albumen having been driven towards one end. With that exception, especially considering the dull weather, they were all that could be desired—remarkable indeed for softness and half-tone. The exposure this month, after three o'clock, with a quarter-inch stop and stereo. lens, was from twelve to fifteen minutes.

Mr. Mabley: The pictures have now been delivered to the members of the Exchange Club. Before we break up for this evening, I have a suggestion to make in reference to future proceedings in that direction. According to the plan which we have just carried out, nearly another year must pass before we could effect a second distribution; and I therefore propose another plan, the basis of which should be, that a portfolio be kept for the reception of pictures which may at any time be exchanged by members of the Society. Not only would this provide for a perpetual exchange, but it would obviate many difficulties to which the scheme we adopted has been found liable.

Several members having expressed a desire that this principle should be properly considered, the following gentlemen were appointed to report thereon:—Mr. Mabley, Mr. Mann, Mr. Sidebotham, and Mr. Wardley.

A vote of thanks having then been passed to the Chairman, the meeting was adjourned.

CITY OF GLASGOW AND WEST OF SCOTLAND PHOTOGRAPHIC SOCIETY.

The second monthly meeting of the above Society was held in the Religious Institution Rooms, on Thursday, the 1st instant,—J. Kibble, Esq., the President, in the chair.

Mr. Ewing read a paper—*Remarks on Failures in the Albumenising, Printing, and Toning of Positives on Paper*, illustrated by several prints showing failures commented on. [See page 331].

On concluding the reading of the paper Mr. Ewing sat down amidst much applause.

A conversational discussion ensued.

The Chairman remarked that the cause of the measly appearance in prints was the use of too weak hyposulphite, causing the formation of sulphuret of silver; that the brown spots were sulphuret of silver, and that no amount of after-washing or immersion in hypo. would dissolve them.

Mr. M'Farlane exhibited prints having the two kinds of disease which were designated measles; the numerous small red spots on the surface, and which all now agreed was on the albumen; and the brown spots or patches best seen by transmitted light, and which he thought were caused by too weak hypo., as explained by the Chairman.

The Chairman showed some small pieces of paper which had become spotted by being kept in a damp place. A small piece of the paper on which he printed his forty-inch pictures showed these numerous transparent spots very evidently.

Mr. Hugh Wilson directed the attention of the meeting to the getting of what the engraver would call a metallic surface on the paper before printing on it.

Mr. Stuart explained that he had recommended that in his paper read at last meeting.

Mr. Wilson said he proposed it at a former meeting.

Mr. Ewing said he believed neither of them were the original proposers of this simple matter.

Mr. Stuart showed a print produced on the paper enclosed in the preservative case at last meeting; but, having been two days in printing, it could scarcely be considered a fair example of what the case would do.

The subject of printing was again to be continued at the next meeting; Mr. A. M'Nab to lead off.

The Chairman then read a paper on some experiments he had made in reference to Messrs. Petschler and Mann's process, and showed the various pictures referred to in his paper. [See page 326.] He concluded by proposing that the thanks of the Society be awarded to Messrs. Petschler and Mann for the unreserved manner in which they had given their discovery to the world.

The Secretary then intimated that he had been deterred by some business requirements from referring at last meeting to his safe return from the Holy Land, but he would then take the opportunity of proposing that the thanks of the Society be given to Mr. J. Spencer, jun., for his faithful discharge of the duties of secretary during Mr. Cramb's absence.

The thanks of the meeting were then given to Mr. Kibble and to Mr. Ewing for their papers.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

The Fourth Annual General Meeting was held on Tuesday evening October 30,—Mr. W. B. Osborn, vice-chairman, in the chair.

The Treasurer, in the absence of the Secretary, having read the notice calling the meeting, a letter of apology for non-attendance from Mr. C. L. Haines, V.P., and the minutes of the previous meeting, which were confirmed, then read the Report of the Council, which stated that, although the Society was in a prosperous and satisfactory state as regarded its financial position—the Treasurer's statement of accounts showing a balance in hand of £14 14s. 11d.—still the Council could not but regard with regret the apathy and indifference evidenced by the members in their attendance at the meetings of the Society, and which had been so long continued, in spite of the exertions of the Council to provide subjects of sufficient interest to induce the members to attend, and to the so great discouragement of the Council, that several of the officers had intimated their intention of resigning their offices and membership at the close of the session just concluded. During the past session one presentation of photographs had been made among the members, and papers upon the following subjects had been read:—*Hints connected with the Dry Process*, by Geo. Shadbolt, Esq.; *The Serio-Comic Aspect of Photography*, by Mr. W. B. Osborn, V.P.; *The Fothergill Dry Collodion Process*, by Mr. Alfred Keene, of Leamington; and one very interesting evening had been spent in a discussion upon the relative merits of the "Wet" *versus* "Dry" processes, on which occasion a large number of magnificent photographs were exhibited, as specimens of the productions of each. During the past session five new members have been elected, and eight tendered their resignations,—the number at present on the books of the Society being *thirty*.

The report of the Treasurer showed that a balance remained in his hands of £14 14s. 11d.

The following list of officers, proposed by the Council for the ensuing year, having been ballotted for, were duly elected:—*President:* The Right Hon. Lord Calthorpe; *Vice-Presidents:* Mr. W. B. Osborn and Mr. C. L. Haines; *Treasurer:* Mr. Jno. Thos. Brown, Jun.; *Secretary:* Mr. Jno. Thos. Brown, Jun., *pro tem.*; *Council:* Dr. Hill Norris, Mr. Rejlander (Wolverhampton), Mr. Hart, Mr. Morris, Mr. Robinson (Leamington), Mr. J. Turner, Mr. Hunt, Mr. H. H. Plante.

On the motion of Mr. Jno. Thos. Brown, Junr., seconded by Mr. Rejlander, it was unanimously resolved,—That Rule 6 be altered as follows:—"The Council to have the power of electing Honorary Members."

Mr. Rejlander having laid upon the table, for the inspection of the members, a portfolio of his inimitable pictures, "Studies from Life," and Dr. Hill Norris a series of very beautiful specimen prints from his new extra sensitive dry plates, together with the negatives from which they were produced, a vote of thanks was given to those gentlemen.

An interesting discussion on Dr. Norris's prints and negatives is anticipated at the next meeting.

During the evening Mr. Rejlander promised a paper for the forthcoming meeting of the Society *On the Camera of Horrors*. It is hoped that the photographers of the neighbourhood generally will muster largely on the occasion.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

[Owing to the great pressure on our space for this number, we are compelled to postpone the continuation of Mr. Wall's valuable "Instructions" till our next publication.]

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent, with a stamped and directed envelope *for their return, to* A. H. Wall, Esq., 11, The Terrace, Walworth.

Notice.—I am compelled, by the increased number of correspondents who have forwarded stamped envelopes for private replies, to state that my many duties (willing as I am to oblige, and anxious as I am to please where I can) quite prevent the sending of such to any but personal acquaintances or friends. Besides this, the publication of replies in many cases kill several birds with one stone; as the information "J." wants may be exactly that which "K.," "L.," "M.," and the rest of the alphabet, thought of, or were about writing to me for. Letters I now have shall be replied to on the first leisure evening I have, but for the future I hope not to receive such requests.

Rosabelle.—See an advertisement in the present number (to which also I should be glad to direct the attention of several other pupils who made similar inquiries some time since). The picture did not reach me.

L. Goodwin.—Such a vehicle may be made as follows:—Take gum anime half-an-ounce, with one ounce of gum sandarach; reduce to a fine powder and dissolve them in spirits of wine; place the solution in the sun until the gums are perfectly dissolved, and then filter into bottle for use. This is very useful for glazings.

L. M. and G. R. are referred to portions of these articles now published. The repetition of information already given would, justly enough, displease regular readers and subscribers.

Foreign Correspondence.

Paris, November 10, 1860.

DECIDEDLY our laborious tribe of photographers are almost exclusively occupied at present by two questions—the amplification of pictures, and the carbon-positive printing. The opening meeting of the French Society of Photography was nearly wholly taken up with communications on these two subjects. Among the general public also, nothing has been talked of for some time past but the full-length, natural-sized portrait of the Emperor, executed by M.M. Mayer, Brothers, and Pierson, and exhibited every evening at their door on the Boulevard des Capucines, with an ample accompaniment of gaslight. Those who know Paris and the Parisians, will easily conceive how this curiosity is looked upon as an event. "Have you seen the Emperor's portrait, by Mayer?" "No." "Well, you must see that—a photograph of natural size." "Indeed!" "And perfectly executed; go and see it this evening." "I will, certainly." And so people go there and keep up a constant crowd before the portrait. There are only a few among the spectators who can account for the manner in which the gigantic picture was obtained.

Before the exhibition of the Emperor's portrait, the pony of M. Edward Delessert drew the strollers toward the windows of one of our publishers, where it was on view. A pony of natural size—a picture six feet by five feet! Count Aguado, who, the other evening, presented to the Society a series of groups of animals—likewise amplified with the apparatus of Woodward, but in more limited proportions—had to do with a less easily-satisfied and more competent public, which did not prevent his beautiful picture from being greatly admired. I have seen them, and that by Mayer and Co., and I can assure you that they are all extremely remarkable. But now there comes a new process and a new apparatus to surprise us, and to fix the attention of connoisseurs. A few weeks ago, a M. Wothly, of Aix-le-Chapelle, forwarded to the Academy several portraits photographed at two-thirds of the natural size. In the note accompanying them he says:—"I have arrived at unhoped-for results by a combination of means which constitutes almost a new art. An optical arrangement, analagous to that of the heliostat, gives me a pencil of rigorously parallel rays, which passes through the negative obtained upon the collodionised half-plate, carries with it the image, becomes positive, and spreads out in an immense cone of divergent rays, which fix the picture upon a sheet of sensitised mechanical paper. The intensity of the rays is sufficient to produce the positive in from fifteen to twenty minutes when the operation takes place in the open air. The regularity of their distribution and direction is such that the impression is as clear at the extreme edges as it is in the centre, even when the picture is eight feet six inches in height, and five feet in width. To bring down the duration of the printing to so short a time, I have had recourse to new combinations of sensitising agents. For the operations of washing, toning, and fixing upon such unwieldy sheets, manipulations as rapid as they are efficacious have taken the place of the impracticable dishes. My half-sized and full-sized portraits have, it seems to me, a character of their own; having a greater attraction for the eye, and charming it more agreeably. The harmony and the blending of the tints are such, that these portraits remind one, more than do the ordinary photographs, of the pencil-work of some talented draughtsman. I may say that they are scarcely affected by the influence of the light, as my fixing process renders them proof against all sulphuration."

Two or three days after this communication, it was learnt that Disdéri had just purchased from the author the secret of his invention, and the right to work it in France, at the price of 20,000 francs. I have seen the specimens of this new process at Disdéri's, and I must say that they are strikingly beautiful. The advantage of M. Wothy's discovery is said to be specially in the preparation of the paper. I can readily believe it; for it would be difficult to find pictures superior to these in clearness, in modelling, and in harmony of tone. In all points they are complete. As to the apparatus which produces them, I know nothing more than what is said by the author in his note.

Will M. Quinet have this apparatus and the specimens seized, as he did those of Bertsch and of Woodward? Up to the present time I have heard nothing said on the subject; but, at the opening of the meeting of the French Society, I witnessed a scene which will give you an idea of the unpleasant position in which the said M. Quinet has placed himself with respect to photographers. Without being a member of the Society, and without having received an invitation, he went to the meeting, at which were to be present most of those whose labours he had interrupted, or whose works he had confiscated. Great was the general surprise at his appearance. In spite of the representations of the Secretary, who had taken him into his cabinet, he persisted in staying. He was then requested aloud to retire, which at last he did, though not without attempting to discuss the vigorous measure which he had so unfortunately provoked.

Two communications relating to carbon-positive printing were made at this meeting. The first was from M. Poitevin. His process is based on the property possessed by a mixture of perchloride of iron and tartaric acid of absorbing the ambient humidity of the atmosphere when exposed to the light. If, then, a negative be placed upon a layer of this mixture, the parts upon which the luminous rays have acted will alone absorb this humidity: the other portions will remain inert. The author operates upon glass, porcelain, ivory, and paper: in this last case he transfers. The following are the three examples which he gives in his communication:—

To operate upon ground glass: clean well, and pour upon the glass a mixture of 10 grammes of perchloride of iron, and 4 grammes of tartaric acid dissolved in 100 grammes of water, and then let it dry. If it is polished transparent glass, we first cover it with collodion; and while the layer is still wet, we pour upon it the above mixture, which we then let dry. In both cases, when the surface is completely dry, we expose it for five or ten minutes under a *cliché* in the sun. On leaving the frame, the picture is not very visible, but the parts acted on absorb the humidity of the air, and can retain the colouring powders laid upon them with a pencil. If it is a transparency that we wish to obtain, we wash with alcoholised water, acidulated with chlorhydric acid; we dry and then varnish. To obtain a picture upon glass, we use an enamel or metallic oxide as a colouring matter, with a flux, and we pass it on to the fire. Lastly, to transfer to paper, as soon as the carbon design has been obtained, we cover it with normal collodion. We wet this layer abundantly, then wash it, first with acidulated water, then with common water; after which we lay upon it a sheet of gelatine paper, and let dry. In taking away this sheet, we also take away the collodion upon which the carbon design has become fixed. We varnish, and then fasten the picture upon cardboard.

Such is the method. It is certainly very ingenious; but it has not yet sufficiently answered in practice. If we may judge from specimens sent to the Society, and which were obtained directly upon paper, M. Fargier's method is much more applicable. Unfortunately M. Fargier keeps the secret for himself.

The presentation of two portable operating-rooms, one by M. Bertsch, and the other by M. Titus Albitès, which latter I have already described to you, completed the proceedings of this meeting, in the course of which M. Girard had also presented some pictures of the eclipse, obtained by him at Batna, in Algeria.

ERNEST LACAN.

TO SUBSCRIBERS AND AGENTS.

☞ **Should any of the Subscribers or Agents to this JOURNAL require additional Copies of the present Number, they should address the Publisher on the subject not later than the 20th instant.**

Correspondence.

☞ **We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.**

ATTACHING THE FILM, &c.

To the EDITOR.

SIR,—From remarks recently made in THE BRITISH JOURNAL OF PHOTOGRAPHY, it seems that the adhesion of the film to the glass is still a desideratum. If so, I trouble you to say that I have for some time albumenised the edge of the plate with a camel-hair pencil, to the extent of about one eighth of an inch; when dry, collodionise, &c., and it will bear any amount of washing the collodion itself will support.

I have thought that, were the proof immersed in gelatine, no evil would result from the use of even common paste; and I believe the paper would be also fit for colouring. I may be in error: if so, will you kindly tell me?—I am, yours, &c., T. L. MERRITT.

November 20, 1860.

[We are glad to greet an old correspondent again. Is the albumen on the edge of the plate only less trouble than having it all over? We scarcely think so. Without doubt, immersion of the proof in *pure* gelatine might afford some protection; but what are we to regard as *common*

paste? that which we make of flour and water only, or that which we buy? If the latter, we do not know what injurious matter it may contain. We recommend you to read the close of a paper by Mr. Stuart in our last number, pp. 314 and 315.—Ed.]

AUTOMATIC WASHING TRAY.

To the Editor.

Sir,—Your correspondent, "Mr. W. Church," seems to be in error as to the action of a syphon, such as described by "H." Directly the level of the water in the washing apparatus falls below the end of the short leg of the syphon the air rushes in and entirely empties it, so that the water will not begin to run off again until it reaches above the level of the bend, when, owing to the great excess of exit area over that of the ingress, the trough will be speedily emptied; and this alternate action will proceed for any length of time (until the supply of water ceases) without any attention whatever.—I am, yours, &c.,

November 5th, 1860. AMATEUR MECHANIC.

[It is our present correspondent who is in error. Mr. Church was quite right in objecting that the great excess of exit area over that of ingress would prevent the water from filling the orifice of the exit pipe above the level of the bend, and, consequently, prevent the syphon being brought into play *as a syphon*.—Ed.]

A FEW WORDS IN REPLY.

To the Editor.

Sir,—On perusing an article in the last number of the Journal, intituled, "Photographic Comments, No. 14," by T. F. Hardwich, I feel tempted to ask your permission to make a few remarks upon it.

In the article in question, Mr. Hardwich takes me seriously to task on account of some observations I made in an address to the members of the Chorlton Photographic Society, in September last, *On the Present unsatisfactory state of our Knowledge of Photographic Chemistry.*

I have just refreshed my memory, by a reference to the report as it appears in your Journal of the 1st October, and I must confess my inability to discover anything in it to give rise to the views advocated in these comments; for I cannot suppose it to be because I call in question the *absolute* perfection of the formula recently given by him for the production of a "definite gun-cotton, well suited in *every* respect for making collodion."

I did not arrive at that conclusion after a slight and superficial acquaintance with the subject, nor without having ascertained what were the opinions generally of others more practically acquainted with its results.

In making that statement I had not the most remote intention to detract from or undervalue the importance of the researches of Mr. Hardwich, but rather to point to them as worthy examples of what had already been accomplished by diligent and careful experiment.

With regard to the opinion expressed, that such addresses tend to retard, rather than advance, the progress of the science, I will only observe that others, in common with myself, from their experience, hold a contrary opinion.

I may be wrong in thinking that, if the attention of members of photographic societies were more frequently directed to the comparatively imperfect state of photographic chemistry, many ardent admirers of the art, who now mechanically perform all the delicate operations which its practice involves, without ever troubling themselves about the why and the wherefore, would be induced to apply themselves with energy to the solution of some, at least, of the problems that remain to be solved.

I feel persuaded that the sooner we disabuse our minds of an idea, which is very prevalent, that the investigation of the chemical phenomena of photography belongs to, and ought to be left exclusively to, the professional chemist, the sooner are we likely to have the number of minds engaged upon it increased; and, as a consequence, we may reasonably expect that its progress will be more rapid and satisfactory.

I am not insensible to the difficulties that attend all purely scientific investigations; nor am I so sanguine as to expect that we can, without much trouble, or in a short time, bring our researches to a satisfactory conclusion.

The Chorlton Association may or may not include some who require to be constantly patted on the back by way of encouragement, in order that they may be prevailed upon to continue any scientific or other investigations upon which they may be engaged. But admitting the policy of pursuing such a course, with minds so constituted, it does not therefore follow that the simply passing in review some of the facts and phenomena which still remain unexplained will have the effect of paralysing their energies. On the contrary, I believe its tendency would be to produce an opposite result.

The hypothetical case, of the president of a medical society opening a session by an introductory lecture on the present unsatisfactory state of our knowledge of medicine, is not such an one as is applicable to the case, for, however desirable it might be in itself that such lectures should occasionally be given, the fear of disturbing public confidence would at once point out their impolicy.

I do not know whether the majority of the readers of photographic journals agree with Mr. Hardwich, that the matter they are expected to contain should be of such a light and easily digestible kind as to entitle them to take rank only with the daily newspaper or other periodical literature. For my own part, I have always looked upon them as partaking more of the scientific character, and as such deserving and requiring more than a passing glance.

It is with extreme regret I find myself at variance, even in such minor matters, with a gentleman so distinguished, and to whom we owe so much, in the chemical department of our art. But holding the views I do, however erroneous, as to the manner in which the science can be best advanced, I have felt it incumbent on me not to allow the opinions of even so high an authority to pass unchallenged.—I am, yours, &c.,

W. GRIFFITHS.

November 8th, 1860.

ANSWERS TO CORRESPONDENTS.

T. G. —Received with thanks.

Geo. M.—It is not of sufficient interest to be entitled to a notice.

F. P.—We do not coincide in your view of the matter in any way. Perhaps one of our contemporaries may, though we doubt it

R. S.—It must depend upon your requirements. Without you state what you want to do exactly, it would be impossible to say what amount would provide you a proper outfit.

Thos. Quinlan.—Mr. Wilson, of Aberdeen, will be able to supply your wants; or you may procure his productions in several of the shops of the London dealers.

Dipper.—We are constrained, from press of matter, to postpone your communication; it shall, however, appear in our next.

R. F.—Your sensitising bath has no doubt become impoverished: add more nitrate of silver.

Tinner.—Your crystals are protosulphate of iron, and require no preparation to fit them for use—except perhaps, if dirty, solution in pure water and re-crystalisation.

J. Magrath.—The third on your list is in our estimation the best; but different operators work most readily with different kinds. Much also depends upon the class of work which you wish to execute.

Quartz.—We believe that geological illustrations are to be had of Mr. Gutch. We remember to have seen some excellent specimens, by this gentleman, at one of the Photographic Society's Exhibitions a few years ago.

F. B. D.—You have not properly removed the iodide of silver from the edges of your plate: hence the white patches in the print. Leave the hyposulphite solution on a little longer, or use it a little stronger. The pose is not bad.

Troubled.—Asking us to recommend a camera is like asking a stranger to recommend you a house. How can we advise discreetly without knowing to what purpose you wish to apply it?

Margaret L.—We think that Mr. Skaife's small apparatus, which he calls a "pistolgraph" (a tool infinitely better than its name), is exactly suited to your requirements; and with very moderate care you need not soil your fingers.

R. Peers.—A swing-back camera does not require a sliding front any more than an ordinary camera, but for landscapes we should regard both as imperfect without sliding fronts.

J. A. R. (Retford.)—1. A small-sized portrait combination by a first-rate maker. 2. Possible; but not advantageous or economical. 3. A quarter-plate, or a smaller one better still. 4. Same as the preceding, with diaphragm between the lenses. 5. Sometimes the last-named, at others the ordinary view lenses.

Victor.—Too late for our last. If you develop with pyrogallic and citric acids the colour will be bluish black; if with pyrogallic and acetic acids a reddish tone will result. By mixing the two in various proportions, browns of almost any shade between the extremes may be obtained. Covering the film while wet with hydrosulphate of ammonia and water will also turn the deposit of a brown colour.

A Printer's Devil.—Too late for reply in our last. Sensitised paper discolours very rapidly in the presence of *moisture*: it is therefore probable that your blank paper book is damp. Use a little free nitric acid (very little) in your sensitising bath; dry the paper thoroughly, and keep it in a tall wide-mouthed bottle, well corked. We have never seen the effect you describe in the skies. We do not advise any automatic washing apparatus.

Kelvedonensis.—1. Use a little ox-gall and gum-water with the colouring matter. —2. We do not know the preparation you mention, except by name; but *good* negatives and positives cannot both be obtained with the same collodion without some modification.—3. Chloride of calcium greedily absorbs moisture, hence it hastens the drying of bodies enclosed in a case with it.—4. We believe the advocates of the process named say for several weeks: we do not personally think well of it.—5. See a note from Mr. Rodgers in the present number.

We are informed by a correspondent that a tent purchased by him in consequence of a description he read of it in the letters by Simeon Headsman, although well adapted to his purpose in other respects, was so badly made that, by a tolerably strong shake it would come to pieces—that rods described as of brass were, in his specimen made of iron—and that a gutta percha tray with a tube to carry off the waste water, had the tube so far projecting into the tray that its intended use was completely obviated, and the tent flooded with the washings, &c. from the plate.

We can depend upon the correctness of the description of our contributor; but it is impossible for him to divine that inferior articles to those exhibited to him will, in some cases be supplied to the public. It appears also, to us, very dishonest on the part of the dealer.

R. T. D., a Novice.—No apologies: we are always willing to lend a hand. There is a very simple and cheap vessel in which you can prepare your arrowroot that is preferable to a tinned saucepan—we mean a common earthenware pipkin. It is probable that the paper may be properly coated by floating. A very satisfactory proof upon arrowroot-coated paper was exhibited by Mr. D. W. Hill, at the last meeting of the North London Photographic Association. We note your remarks on "what to avoid," and will give a hint. Skies should *not* print white, especially if the negatives have been taken in dull weather—a condition of things which we perceive existed when you took the National Schools (in which the sky is stopped out), though a slight gleam of sunshine appears in the other. The fact is, that from the low actinic power of the light at the present season a long exposure is required to obtain details, and sometimes the sky is thereby very much weakened in density. A small quantity of dilute albumen added *while developing*, will materially increase the vigour of your negative—but beware of developing too far.

⁂ An unusual pressure on our space has obliged us reluctantly to hold over till our next many valued contributions, among which we may enumerate *Photographic Comments, No.* 15;—*Observations on Albumenised Paper and Alkaline Gold Toning, No. IV.; Photogenic Tribulations;—Photographer's Holiday in Derbyshire;*—Continuation of Mr. Wall's *Practical Instructions on Colouring;*—Mr. Malone's interesting paper, read at the late meeting of the London Photographic Society, communications from "W. R." and "R. G.," &c., &c.—all of which are in type.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

All Advertisements *and* Letters *on the* Business *of this* Journal *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 131, Vol. VII.—DECEMBER 1, 1860.

NOTICE TO SUBSCRIBERS. — With each copy of our number for December 15th will be presented to our readers a MINIATURE PHOTOGRAPHIC ALMANACK, produced under the superintendence of Samuel Highley, F.G.S., F.C.S., &c., which will contain, besides a Calendar for the year 1861, " A Retrospect of our Photographic Year;" Days, Hours, and Places of Meeting of Photographic and Scientific Societies in Great Britain and Ireland; Formulæ for Wet, Dry, Instantaneous, Negative, and Positive Collodion Processes; Waxed-Paper Process, Printing Process, &c; "Photographic Olla Podrida," Useful Tables, Measures, Notes, &c. The particular form adopted has been selected in order to facilitate frequent reference at *all times*. It is proposed, also, to issue copies of the Almanack to non-subscribers to the Journal, at 3d. each copy, in order still further to encourage attention to our fascinating Art-Science.

In our number for the 1st ult. we published a communication from our esteemed correspondent, Mr. Corey, of Liverpool, in which he called upon us to express our opinion relative to the dry process originally suggested by the Abbé Despratz, and which some of our Liverpool friends, including Mr. Corey, have found to be in their hands highly satisfactory. The process consists in employing collodion containing a small quantity of pure white rosin in addition to the other usual ingredients. The manipulation is precisely the same as for ordinary wet plates, with the exception that, after being taken out of the sensitising bath of nitrate of silver, they are copiously and freely washed, and then set aside to dry. It is alleged that these plates retain their sensitiveness unimpaired for a very considerable time, and are more quickly impressed than any other dry plates which our correspondent has ever tried.

We regret that we are unable to share the enthusiasm of Mr. Corey in favour of the rosin process, for the following reasons, viz.:—We find that the film formed by this kind of collodion is unusually liable to be defaced by small white spots, about the size of a pin's head, no doubt from the presence of very minute particles of insoluble matter in the rosin, which have not sufficient gravity to cause their perfect deposition, by allowing the collodion to remain undisturbed for a considerable time. We find, also, that the film, after development, is particularly apt to strip off the plate in the subsequent drying, splitting up into innumerable shreds and fragments. It is contended that this latter evil can be remedied by coating it with albumen before the final drying—a proposition which we admit. We have compared the sensitiveness with that of plates prepared by the Fothergill process, and in our hands they are unquestionably inferior in that respect to the latter; while, as regards "keeping" qualities, we have found that it is quite possible to preserve the Fothergill plates for upwards of *ten months* in a highly sensitive condition. We have been favoured with several specimens of prints from plates by the rosin process; but, with the exception of one by Mr. Corey, they all displayed the evidence of weakness in the negatives—the exception, in our judgment, exhibiting under-exposure, though in this case we are informed that the operation took place during a shower; therefore, we may presume that, had the weather been more favourable, the result would have been, in Mr. Corey's skilful hands, satisfactory. We have, however, kept to the last our chief objection to the process, which is, that the introduction of the rosin ought, upon theoretical grounds, speedily to throw the sensitising bath out of order. We cannot imagine that an organic substance like rosin, brought into frequent and intimate contact with nitrate of silver, can possibly fail of contaminating it in such a manner as effectually to deteriorate, if not eventually destroy, any certainty of actinic action upon the film: judging from the pernicious effects of carbon, even when used merely as a centre of crystallisation for nitrate of silver, as distinctly proved by our *collaborateur*, Mr. Hardwich, we are unable to believe that a carbonaceous substance like rosin can be innocuous when introduced into the nitrate of silver bath. We do not *know* this from actual experiment, simply because we have held the process in sufficient disesteem, upon these scientific grounds, to deter us from making more than a few trials of plates prepared by it; and the result of these trials, being discouraging, has not induced us to pursue the investigation further.

We demur, also, to the alleged pre-eminent simplicity; because, if it be necessary to coat the plate with albumen at all (*e. g.* to prevent destruction of the film at the final drying after development), it is surely no more trouble to perform this operation before the first drying, and prior to exposure; while the advantage of this proceeding is obvious in the entire or partial coagulation of the albumen by contact with free nitrate of silver, and thus its non-liability to decomposition by moisture to some extent is effected.

If our allegations be well founded, we submit that we have adduced sufficient for holding the rosin process in disfavour; but if not, we shall only be too glad to be obliged to recant, by the excellence of the productions which we trust that our Liverpool friends who follow this process may show at some of the forthcoming exhibitions. We by no means claim infallibility for the correctness of our views, and are ready to change them if proved to be wrong; but, as we do at present entertain them, called upon publicly as we have been, we have no option but to give expression to them. Liverpool photographers are far too earnest seekers after excellence to feel annoyed at the non-agreement between themselves and us upon what is, after all, but a mere matter of opinion.

We certainly experienced no small amount of surprise at the turn which was given to the discussion on Mr. Rothwell's paper at the last meeting of the London Photographic Society. We can well enough understand how thoroughly unintelligible such a paper would be, even to minds of a mathematical bent, when not only all the geometrical and arithmetical calculations, but the diagrams also, were omitted; but to the generality of those present it might almost as well have been delivered in the vernacular of the Cherokee Indians. That which makes the proceeding the more singular is an announcement in the September number of the Society's organ, at p. 330, that "Mr. Rothwell is desirous that gentlemen should come prepared to discuss the merits of the subject on which he treats;" yet, in consequence

of his own absence, which we much regret, and presume was unavoidable, his communication was mutilated, and the discussion was really diverted from the subject of the paper, chiefly to a consideration of some of the first principles of perspective, as indeed was noticed by one of the speakers. While upon this subject we cannot forbear remarking that, had those gentlemen who advocated the propriety of depicting parallel lines in nature by converging ones in the drawing when the plane of delineation is placed parallel to the object, only perused the conclusive papers *On Perspective and Distortion*, by Mr. Grubb, published in the current volume of this Journal, at pp. 74 and 143, they would in all probability have had clearer views on the subject; and we strongly advise those who feel an interest in it to re-peruse the articles to which we refer.

An elegant application of photography has been made by Mr. John Louch in multiplying copies of monumental "brasses," as they are termed. From an ordinary rubbing, a negative is formed in the pressure frame by exposure to light, and this is fixed and waxed in the ordinary manner. Sensitised chloride papers are then exposed under the negative until the parts which are bright in the original "brass" are thoroughly *bronzed*, and the parts corresponding to the *blacks* of the negative (that is the *lights* in the positive print) have become black from very extended over-exposure. A dense and well-defined negative is that best to operate with; and the positive paper should be both rich in chloride and also in free nitrate of silver, but not highly albumenised. The printing should be slowly performed in diffused light. The proof then requires fixing and toning with gold, the bath being tolerably rich in the latter material: the effect produced being to *deposit the gold in a metallic form* upon the bronzed portions of the proof, while the other parts acquire a rich black colour, so that the finished specimen bears a striking resemblance to the original "brass."

The specimen with which we have been favoured by Mr. Louch, though not perfect, indicates unmistakeably the feasibility of the scheme; and we have no doubt that such method of reproduction will become highly popular amongst those whose taste lies in this direction.

We understand that Mr. Aspden has been appointed Local Assistant Secretary for the Manchester meeting of the British Association for the Advancement of Science, next year. This gentleman is a member of the city council, and we should imagine that municipal influence had much to do with securing his election. Judging from a photographic point of view, we should certainly have given the preference to another candidate whose general qualifications render him exceedingly suitable for this onerous appointment.

PHOTOGRAPHIC COMMENTS.

By T. F. Hardwich.

No. 15.

We have, at various times, endeavoured to prove the importance of using pure nitrate of silver for the negative bath; and a reference to the back numbers of the *Journal of the Photographic Society* will show no less than four communications of ours upon that subject. The following extracts give an idea of the facts and opinions at the time when these papers were written (May 21, 1858):—"Both the fused and the crystallised nitrate of silver are found occasionally to fail in the negative collodion process. Some samples appear good, and others bad, without any very obvious difference between them being observable. On one occasion a negative bath was prepared from the commercial crystallised nitrate of silver, the trace of nitric acid being neutralised, and the solution acidified faintly with acetic acid. This bath was taken into the field, with an ordinary landscape camera for plates nine inches by seven. The collodion was rather an intense sample, simply iodised, and inclined to give red negatives, so that success ought to have followed as a matter of course, without the use of acetate. So far from such being the case, however, everything went wrong. On applying the developer it was evident, by the manner in which the sky came out, that the picture would be a failure. The image was thrown down in the grey and metallic form, and there were numerous spots and brush-like prolongations from various parts, such as the spires of a church, &c., giving the appearance as if the image had been imperfectly focussed. The cause of the defect, however, was in the bath; and, fortunately, a friend, who lived near, was able to provide another bath, with which good pictures were taken.

"To ascertain, if possible, the cause of the above peculiarities, another sample of impure nitrate of silver was examined, and the conviction gradually arrived at was, that it contained traces of some organic matter. No positive opinion can be given as to the source of the organic matter; but attention may be called to the fact that, in the assay processes, it is usual to employ small fragments of charcoal to prevent 'bumping' of the acid, and in consequence the acid acquires a brown colour. It is questionable whether one crystallisation is sufficient to free the salt from such a contamination."

The following extract is from a paper bearing date September 21st, 1858:—"Doubts having been expressed as to the correctness of statements made in this Journal on impurities of nitrate of silver, it seemed advisable to institute fresh experiments, and especially so as the principals of a firm who manufacture nitrate of silver on a large scale, agreed to render every assistance. Samples of the acid mother liquors which furnished the crystals, were evaporated to dryness, and then pulverised and dried at 240° Fahrenheit. The following were the results obtained on comparing the impure with the pure nitrate:—

"*No.* 1 (Pure nitrate).—Time of exposure for a stereoscopic view in a moderate light, fifteen seconds. The image develops with a full amount of intensity, and has a tone of red in the sky: superficial bloom well marked.

"*No.* 3 (Thought to contain only a small amount of the impurity).—Exposed fifteen seconds, as before: this was too little. With thirty seconds in the camera a tolerable picture was obtained, but the development was less vigorous than with the pure bath; and the whole image, but particularly the sky, appeared grey and metallic. An indistinct appearance was observable about the lines of the picture, which were blurred, not from defective focussing, but by a deposit of silver taking the direction of the draining in the slide. A chimney, for instance, appeared to have smoke issuing from it, although nothing of the kind was visible upon the ground-glass of the camera. Most frequently the blurring was of the opaque kind, but sometimes the reverse obtained, and a translucent halo was seen. When the sun shone out strongly the blurring nearly disappeared. Different samples of collodion were next tried. Those succeeded best which produced red and intense negatives in a pure bath; but all gave negatives of inferior quality. One sample of collodion, rather strongly coloured from liberation of iodine, produced an average negative in the pure bath, but gave *a transmitted positive*, nearly perfect, in the impure bath."

* * * * * * * *

The foregoing will suffice as a statement of the defects encountered on the occasions referred to. Having determined, in a manner satisfactory to our own mind, that organic matter, oxidised by nitric acid, was the cause of the want of intensity, and that such nitrate of silver could only be purified by a second crystallisation, we allowed the matter to drop. Latterly, however, we have received fresh complaints of the ordinary commercial nitrate of silver; and the subject has also been brought particularly before us by some remarks made by "S. H.," at page 242 of the seventh volume of The British Journal of Photography:—"Messrs. Hopkin and Williams, in recrystallising nitrate of silver in their own laboratory, have found that they can only obtain 150 oz. suitable for photographic purposes out of 200 oz., and that the remaining 50 oz. from the mother liquor are quite unsaleable."

In consequence of the above remarks, we procured half-a-pound of the unsaleable product referred to, and examined its action in photography. In describing the defects discovered, it appeared unnecessary to write a new paper, since it would have been a mere repetition of the statements contained in those previously published. There was the same poverty in the image, and the same slowness of developing, whilst the exposure required was so considerable as to unfit the bath for use. Looking at the negatives, many would have said that the bath contained nitric acid. But it was not so, for every trace of nitric acid had been neutralised. Since the year 1858 our knowledge of collodion has improved, and we can, therefore, specify more exactly the quality of collodion which fails most signally in such a bath: it is that prepared from pyroxyline made in acids weak enough to yield a product only partially soluble in the ethereal liquid. Every picture will be blurred and indistinct with such a combination of bath and collodion. We

notice, also, an effect of *bromide*, of which we were ignorant in 1858; for, by adding it to the collodion, we were enabled to produce a picture even in the impure bath, whereas with the simple iodised collodion, free from bromide, no details could be obtained in the shadows.

To avoid wearying the reader, by going over old grounds afresh, we will content ourselves with describing one additional experiment, made with a view of indicating the nature of this foreign substance in nitrate of silver. Supposing the impurity to be organic, it ought to be nearly or quite destroyed by very strong fusion. We, therefore, melted a sample of the nitrate of silver, and afterwards raised the heat until a considerable portion of the nitric acid had been expelled, and a deposit of metallic silver left at the bottom of the vessel. The next step was to bring the material back again into the state of nitrate of silver, by boiling with pure dilute nitric acid, until everything had been taken up, and the nitrate of silver decomposed: on evaporation, a white crust of the reconstituted nitrate of silver remained in the capsule. The result of this experiment was most remarkable, and it entirely restored the lacking intensity. Negatives taken in the bath from the purified nitrate had all the bloom and redness of negatives taken at the same time in a pure bath, although, from the nature of the purifying process to which the nitrate of silver had been subjected, we cannot suppose that any inorganic body, such as nitrate of copper or nitrate of lead, had been removed. Everything, in fact, present before must have been present after, with the sole exception of organic matter, which would have been burnt away.

A question arose with reference to this impurity in nitrate of silver: has it anything to do with the difficulties which sometimes occur in the alkaline chloride of gold toning process? Our experiments, as far as they have gone at present, give a reply in the negative. On dividing a sheet of albumenised paper in half, and sensitising one portion on a sixty-grain solution of the pure, and the other on a similar solution of the impure, nitrate, both were found to tone in a satisfactory manner.

NEW PORTABLE OPERATING CHAMBER.

By T. Maltwood.

[Most of our readers will remember that on a former occasion we described a "Finder" for the microscope, in which photography was applied to micrometrical purposes by the ingenious contriver of the following, which he has so well described that we adopt his own words.—Ed.]

That the wet collodion process is generally regarded as possessing advantages superior to any other, is pretty clearly demonstrated by the fact of its being almost universally adopted by photographers when taking pictures at home, where they can avail themselves of the comfort and facilities of a well-lighted and well-fitted dark room.

I think there can be no question that all that has been done in the way of dry plates has been brought about by the want felt of a dark room possessing all the necessary conveniences for operating in, and at the same time sufficiently portable to allow of its being transported to any desired spot, without trying either the constitution or the pocket of the tourist.

I must confess to a decided predilection in favour of dark boxes; and some time back I made one similar to those introduced by Messrs. Burfield and Rouch three or four years ago; but this did not at all satisfy me, and after trying several plans, I succeeded in making the one I am about to describe.

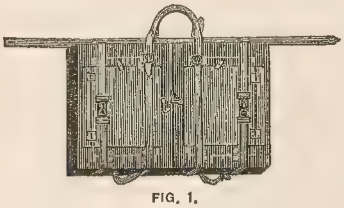


FIG. 1.

It is shown in *fig.* 1 closed, and can be carried by the handle, like a carpet-bag, or on the back by means of straps fixed on the bottom—the size being twenty inches long, five wide, and thirteen inches deep outside.

Fig. 2 represents it open and ready for use, forming a dark chamber twenty inches long, thirteen wide, and fifteen high, raised on legs, which are attached by pins fitting into brass sockets in the bottom of the box. A is a mahogany tray, five inches deep. B B, the flaps that cover it when closed, are fitted with yellow glass in a hinged frame, forming both a window and door at each

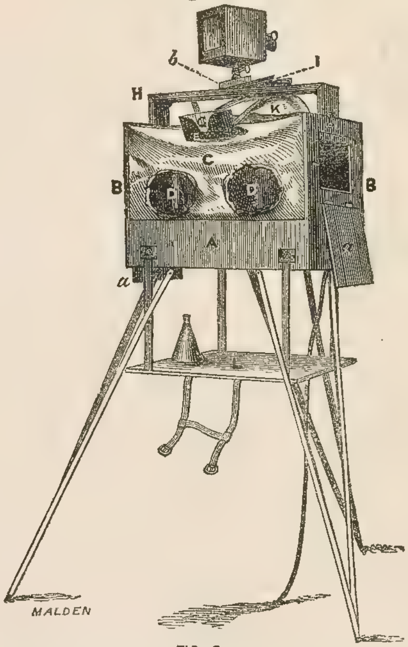

FIG. 2.

end; *a a* shutters to protect the glass when travelling. C is a piece of single texture india-rubber cloth, fixed to the sides of the tray A and flaps B B, by means of which we get three times the size of the tray, and add only a few ounces to the weight. D D are sleeves, through which the hands are passed into the inside. E is a piece of yellow glass, through which the operator looks. G, a piece of loose leather, which can be brought over E, and greatly facilitates seeing what is going on inside, by shutting out external light. The stage, H, keeps the flaps, to which it is fastened, perfectly rigid, and the upper part, I, is made to rotate, not only to get any angle that may be required for stereoscopic pictures, but so that different views may be taken all round the horizon without changing the position of the box. *b* is a small block of wood sliding into I, and is fitted with a spirit level, and a ball and socket which carries the camera. K is a flexible portable cistern (*fig.* 3), capable of carrying about a gallon and a half of water, having a brass cock fixed on one side. This cistern is laid on the top of the box (or may be fixed at the back), and the brass cock, passing through a hole in the india-rubber cloth, places the supply in the cistern at the command of the operator.

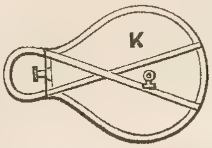

FIG. 3.

The bottom of the tray is divided into three spaces, as shown in *fig* 4, each being separately watertight, and affording convenience for packing the camera, chemicals, &c. The silver bath drops through a hole in the back left hand corner, the large space at the right being reserved for developing and washing, and has a hole with a piece of flexible tube attached, through which the waste water is discharged. L is a shelf, suspended under the box by two straps, which draw up and fasten with hooks and rings, as shown in *fig.* 1.

FIG. 4.

The weight of this box, containing stereoscopic camera and lens, one dozen glass slides, and an abundant supply of chemicals for a long day's work, is as nearly as possible 20 lbs. This may seem a good deal to some; but the convenient form, and the arrangement for carrying it like a knapsack, considerably lessen the difficulty. This I can say from experience, having carried mine during a three weeks' tour last summer, over all sorts of ground, and into every place I could possibly have reached without it.

PALESTINE IN 1860;

OR, A PHOTOGRAPHER'S JOURNAL OF A VISIT TO JERUSALEM.

No. I.

By John Cramb.

Walking into the office of a friend one day towards the end of last March, I was accosted with the interrogation:—"How would you like to go to Jerusalem?" Who would not? No wonder that, without further thought, I replied:—"Few things would please me better; but," I immediately inquired, "why do you ask that question?" "Because," said my friend, "a gentleman of my acquaintance has been for some time hunting up and down for some one to go out to Syria and Palestine, to take photographs of the places of scriptural interest in those countries, and I told him last night I knew the right man for the place, if he would go. "Now," said Mr. B., "will you go?" But, without waiting for my reply, he continued,—"Go home, and consult over it. My friend and I will call on you to-morrow: make up your mind, for there is no time to lose."

Sitting comfortably round the tea-table, after sipping our "Lapsang Souchong," the reader may suppose how I astonished our home circle by the announcement—"I am thinking of going to Jerusalem!" Explanation followed, and we were soon deep in *Murray's Handbook*, *The Tent and the Khan*, *The Land and the Book*, &c.

Next day brought the searcher after Syrian landscapes to my domicile. I soon learned what he wanted; and, among other conditions, found he had made up his mind that no one would answer his purpose who had not been accustomed to working a dry process. We will see afterwards how far this was a wise or necessary requirement. I had for several years successfully practised the old, simple albumen process on glass, which was at once deemed dry enough for any purpose; and it seemed my partial friend had not over-estimated my photographic suitability for the journey. Though I would not probably have been willing to confess I was at all ignorant of the geography, history, and, above all, the present social and political position of the Holy Land, yet I fear it was so; and, to make up, books of travel had to be gone through at an express-train rate their authors never contemplated, and in two or three cases the information so obtained had to be confirmed and supplemented by an interview with the authors themselves. An immense amount of information was wanted in the shortest possible time, and in the fewest words. I wanted to learn, if I could, all that I now know, and mean to tell in this series of papers. All that I could not. On two or three points satisfactory information had to be got before the enterprise could be entered on. The climate, I understood, from the position of the country, would approach the tropical; but on that point I found little distinct or reliable information in the journals of travellers, or by *viva voce* interrogations of those who had been throughout the country. Few of those who write on Palestine have lived in the country, and only a very small number attempt to indicate its temperature, even at the time they were there. And, again, I could find no one who had been there during the months I would likely have to spend in the Holy Land, if I went this season. English travellers are recommended to visit Syria and Palestine in spring, or late in autumn. Spring was already begun, "in name at least," and before I could be there, though I left immediately, it would be far advanced: to delay till autumn the publisher thought would be out of the question for his purpose. And yet why be so anxious for knowing the heat in figures? How much information does it convey to us of how we would feel to be told the temperature at such a place is 56° or 106°? There is so much to modify our feeling under such circumstances,—the amount of moisture in the air, &c. But suppose the proposition be accepted, that whatever heat the people of the country were able to bear I could,—would the chemicals be as accommodating? There was no denying I had to *leap* over this preliminary difficulty by the desire to visit scenes of such transcendent interest; but that could scarcely be expected to extend to iodised albumen. Photographs had been done before, but at what season? A sentence in one of Mr. Frith's descriptions was not very hopeful. He speaks of the collodion *boiling* in the bottle; but adds, he got over that difficulty: he does not, however, say how? I was not proposing to use collodion, and perhaps I would get along, operating at a temperature that boiled ordinary collodion. There was still a "lion in the way." Is the country safe for Europeans, and, above all, is it likely to be so for one travelling alone, as I would have to do? Friends interested in my safety and welfare are alarmed by accounts of plundering Bedouins and equally unscrupulous Fellahs, and visions of a solitary Scotchman enacting the part of a "certain man who went down to Jericho, and fell among thieves," without the prospect of any Good Samaritan to pour oil and wine into his wounds, and the certainty that there was now no inn to which he could be taken.

Not to tire my readers, all objections were overcome, or overridden I should say; and having resolved to go to Palestine, how could I get there? Jaffa, the port for Jerusalem, can be reached in three or four different ways. A French company, the Messageries Imperiales, have a line of steamers, which sail each alternate Sunday morning from Marseilles, *viâ* Malta and Alexandria, to Jaffa. Marseilles is easily and quickly reached by rail through France. This route I chose, to avoid the Bay of Biscay, being a very poor sailor. The cheapest and most direct way of going to the Holy Land is by the excellent screw-steamers plying between Liverpool and Beyrout; and many English travellers, who prefer going by an English ship as far as they can, go by the Peninsular and Oriental Company's steamers from Southampton to Alexandria, and from thence take a passage in either the French, Austrian, or Russian steamers, which call at Alexandria, and land passengers at Jaffa or Beyrout. The Peninsular and Oriental Company also take passengers from Marseilles to Alexandria. Another course may be followed:—go to Trieste by rail, and from thence to Jaffa or Beyrout, by the Austrian Lloyd's steamers.

Presuming it will be interesting to the readers of the Journal, I will now briefly state what I purposed doing, photographically, in the Holy Land; what preparation I made before leaving; what instruments I took with me, and what chemicals; and how all was packed.

It was intended I should take a series of 8 by 10 in. views of all the places and objects of interest I should visit, and as many pairs of stereoscopic negatives. I resolved to albumenise all the glass I should take before leaving. It was considered desirable, in order to reduce the weight as much as possible, that not more than twice the number of glasses should be taken that we wanted of good negatives to be brought home—a rather narrow margin I thought then, and still think. It was resolved I should leave on the 9th April, or in less than a fortnight from the time I decided on going. About 600 glasses had to be coated within that period.

I do not know that it would be interesting to tell exactly the quantity of each of the various "chemicals" I took,—or the number of dishes, funnels, measures, &c., as a different number and kind would be required for another process, or a different manner of working even the same one. I found it somewhat difficult to estimate the quantity of each substance; and in one case the quantity taken fell far below the actual requirement—namely, of acetic acid. I would have required at least three or four times the quantity, or about 124 ounces. The modern photographer's main requisite, collodion, I did not expect to require. I, however, took a little to try a wet plate perhaps, or a collodio-albumen, or a Fothergill one, and as much as anything to see how it behaved in the transit, and under the expected high temperature of the country.

In the apparatus department I took scarcely any duplicates, and would not recommend any to be taken. I had long been accustomed to take my stereos with a camera which, I suppose, I may call of my own invention, though really the principle of its construction is described in an early number of the *Journal of the Photographic Society*. There are no slides, and the plates pass from the box into the camera, and are again returned after exposure into the same grooves in the plate-box. I use two cameras on one stand, a considerable distance apart, but adjustable. As the cameras are but the thickness of the wood larger than the plates used, they are very *small*. I resolved to have my camera for 10 by 8 in. size placed on the same stand, in the middle, between the two stereo. ones. This arrangement I found answered admirably. By it I was enabled to take the large and stereo. pictures at the same time with one stand. I had no 8 by 10 in. camera suited for the journey, and had to have one made. Though made, I presume, as carefully as possible, it stood the climate very indifferently. Its twisting and cracking cost me several plates, and more than once risked the loss of a subject altogether. My old well-seasoned stereos never gave me any trouble more than working at home would, and they were no gems of cabinet work: their superiority mainly lay in being old and well-seasoned, and something in the plan not requiring so exact fitting as slides do. No photographer should risk going with newly-made instruments on such a journey. My lenses were by Ross, and had not their character to gain; and I need not say they were quite as reliable in photographing the *Mosque of Omar* as they had before been in doing the same thing for *Glasgow Cathedral* and the *Arc de Triomphe*.

Having got the apparatus and materials, we had to have them suitably and safely packed. I may premise that there is no wheeled conveyance in Palestine. Everything is carried on the

back of mules, camels, or donkeys. The ordinary behaviour of the first and last in this country did not seem to promise much security for the safety of the glass and the other fragile materials of a photographic outfit. We were, however, assured that Syrian donkeys had more respect for the property of their owners or hirers than their British-born brethren generally manifested. The stock of albumenised glass I packed in the following manner:—Pieces of card-board were cut of the size of the glasses, and their centres taken out, so as to leave about a quarter of an inch all round the margins. These card-board slips are then placed between each pair of glasses, albumen sides to each other, and placed in paper. These are again tied up in packets of twelve, or of six pair rather, and put in paper. The packets so tied up are put in a box, with deal partitions between each parcel. This box, when filled, and having sufficient soft material in each compartment, is again placed inside of another and larger box, having a space of at least two inches all round, filled with soft material. By this arrangement I was able to send home my negatives from Syria without so much as a scratch—not one broken or otherwise damaged. The plan of slinging the boxes over the mule's back require that both sides be equal. It is, therefore, desirable that each box have as near as possible a counterpart in weight, and size, too, in fact.

I had some difficulty in ascertaining how much a mule could carry. I now know that any mule will carry easily, over any Syrian road, bad as they are, about two hundred weight, and a good one nearly double that amount. What a deep sea of terrors this same carrying of glasses and porcelain dishes on donkeys' backs was to me before leaving this country! The reality, I found, with ordinary care, to be as safe as any mode of conveyance I can think of, and incomparably more so than by rail, as ordinarily done. I can as easily suppose a traveller returning from an Oriental country with quite an opposite tale, if he had been accustomed to handing over himself and baggage to the railway or steam-boat company for safe transport to his destination. He would find the ever-imperturbable, large-promising, but scant-performing, Syrian Mukhari no very safe custodiers of either valuable or fragile property, if treated in the manner he had acquired in his Western travels. The muleteers are only reliable when very sharply and continuously looked after; and the ordinary practice of the country is to do everything with the largest possible amount of bullying and scolding. A carefully-loaded mule will travel a day over the most hazardous roads without stumbling; while if the load be improperly put on, it will be a continual source of delay, and may risk the safety of breakable materials, even with the most careful supervision while travelling. As I had always been accustomed to "look after my luggage," to use the language of the railway bills, I had no difficulty in acquiring the habit of being always near my traps while loading and unloading, and never far from them on the road either.

My readers may not be interested in knowing the contents of my portmanteau; and yet I wished the authors of the books I had access to had given more information on common things. The dress required in Palestine during all but the coldest day of winter is as light outer-clothing as we ever wear in this country. Calico or linen suits are best, and most worn in summer. The less one can think of doing with the better during the warm weather. The head is the only part of the body requiring consideration; and European travellers should learn of the natives, of whom it is humorously remarked that they carry their whole wardrobe on their heads. On a Syrian summer day, the stalwart son of Ishmael may be seen clambering the steep sides of the dreary mountains, or scampering over the fertile plains of his ill-governed country, with less than the most liberal modesty would require as a covering for his person, but with as much as a pair of English blankets wrapped round his head! The purpose of this is to keep the head *cool* by protecting it from the direct rays of the sun; to save the wearer from sun-stroke—that most terrible and too-frequent consummation of a residence in eastern countries. A very light kind of hat, made of pith, is the most perfect protection for the head I can conceive; and I would take the opportunity of recommending them to all intending travellers in warm climates. As usually made, they are helmet-shaped, and not over-sightly to our eyes; butth at is soon got over when the time for their use arrives. I use essly loaded myself with under-clothing, as I had been informed the washer-woman was not one of the institutions of Syria. To the lover of spotless linen I can now, however, say:—"Fear not; you can have your 'eureka' done up to the satisfaction of the most fastidious in Jerusalem and the larger cities of the Holy Land."

I must skip much of my preparations, as time presses. In my next I will give the first part of my journal proper.

ON AN ALLEGED NEW PROPERTY OF LIGHT.

By T. A. Malone.

I have, from the first announcement of M. Niepce de St. Victor's alleged discovery of a new property of light, taken a constant interest in the controversy to which it has given rise. I have ever been sceptical as to its truth, thinking it might be explained by a reference to known physical laws. Although I had formed several opinions as to the cause of the result, I took no experimental steps until after the appearance of Mr. Crookes's demonstration that the heat and moisture of the tube, joined to the tartaric acid used, were sufficient to account for the result of M. Niepce's main proof experiment. M. Niepce, thus apparently set right, replied to Mr. Crookes by making the same experiment under a freezing mixture arrangement. He still got the result he had along insisted upon; but he owned that heat and other agents could simulate his original results. Not observing any reply from Mr. Crookes—who I believe was then much occupied—I determined to read M. Niepce's original papers in the *Comptes Rendus* of the French academy. I there found that M. Niepce set out in a manner dangerous for most experimenters, namely, with the notion that light *might* be absorbed by bodies in such a way as to be given out again; the action to be made manifest by photographic papers. A great number of experiments, made in a variety of ways, convinced him that he was right in his conjecture. Disregarding, for the present, his earlier forms of experiment, I decided on examining most scrupulously his latest result, given in reply to Mr. Crookes. I read carefully his note, and was at once struck with the form of his experiment He places between the vessel containing the alleged stored-up light a piece of paper, having impressed upon it what he calls *gros characteres*, which by some odd association of ideas I interpreted to mean the heading of a newspaper. I came upon this thought by recollecting that the French printers use an ink which is very offensive to an English taste; and it at once occurred to me tha the tarry ink might be at the bottom of M. Niepce's result. I had previously made experiments with creosote of wood-tar, and found it to act upon nitrate of silver. Whatever these notions were worth, they induced me to resolve to try at once M. Niepce's experiment, minus the chief agent—the light. I took advantage of the opportunity the London Institution newspaper-room affords to secure a freshly-arrived copy of the *Indépendence Belge*, the bituminous odour of which was unmistakeable. It was the evening edition, and arrived here early in the morning. I at once placed it in a dark room, with its title-page in contact with a paper washed over with a neutral solution of nitrate of silver. I left the whole in the copying-frame for an hour. M. Niepce names six hours. After that time, just as I anticipated, I got by a wash of gallic acid a distinct impression of the printed letters. They appeared to be positive; but on looking at the paper against the light, I found this appearance to be mainly due to the penetration of gallic acid wherever the letters had been in contact: a *differential action* was evidently at work, and accounted for all the appearances. *No light was used by me during the experiment.* A copy of *The Times* newspaper, similarly treated at the same time, gave only the faintest indication of its title: only that I looked for it it would have escaped notice. The other paper was distinct in its action. Upon drying the result a curious appearance was observed: the surface became faintly negative, as though the printing-ink had suspended, on the surface, the reduction of the silver salt. The *back* of the paper now presented an appearance well known to Talbotype photographers, namely, that of a negative become positive at its back. This I think due to the penetration of the gallic acid, and a consequent *internal* spontaneous deposit. These differential actions will doubtless now be made clear in all their relations. Upon informing Mr. Hardwich of my results, he reminded me of a paper by Mr. Busk, who proved that almost any engraving, without exposure to light, could be shown to have the power of suspending the photographic properties of chloride of silver; but, as he uses light at one stage of his experiment, his result differs from mine, and is not accepted by M. Niepce's advocates as a solution of the controversy. My experiment is, I take it, a simple repetition of M. Niepce's, minus the disputed agent, the light. I am still investigating further the exact physical and chemical causes of the varied phenomena which have so long perplexed us. I may perhaps be permitted to say that I regret that I have not been able to confirm the conclusions of one to whom we are so much indebted for the introduction of albumen into photography.

PHOTOGRAPHIC CONTRIBUTIONS TO ART.

There is perhaps no part of the work of a critic so easy as that of fault-finding, and, if he be so inclined, he may generally indulge the propensity, even with justice. To discover entirely the original idea which inspired the artist when producing his work is by no means so simple an operation; because, even if we set aside the possible variation in capacity for apprehending any given idea, it rarely, if ever, happens that the hand of even the most skilful has cunning enough to give full expression to his meaning. It is manifest that this observation does not apply to faults of conception, but to faults of execution. In general, defects of both kinds are found to exist in nearly every work of art. As the demands upon our space are large, especially at the present moment, and consequently the portion which we can devote to our own remarks but small, we purpose, in the few observations which we are about to submit in reference to some new compositions, endeavouring rather to draw attention to a few of the beauties which undoubtedly exist, than to enter into any lengthened analysis.

At the October meeting of the North London Photographic Association we were enabled, by the kindness of the artist, to lay before the members a copy of Mr. Henry P. Robinson's last new composition photograph, entitled "The Holiday in the Wood"—a work which he has had in preparation for many months past, upon which he has expended no small amount of labour, both mental and physical, and which, though possessing some faults, is one that will deservedly earn a large share of commendation. The dimensions of the picture are about 21 by 16 in., and it contains ten figures of considerable size, very gracefully and effectively grouped. The attention is immediately arrested on first glancing at it, and it is not until some time has elapsed that the spectator becomes aware that it possesses any weak points.

The scene is a moderately clear space in a wood, where the ground is uneven, and rises into a little bank—just such a spot as a party of children are sure to select for their playground. Seated upon the bank, a girl is busy making a garland of wild flowers, while another leans against her shoulder, looking on at the work. On the other side is one reclining in an easy attitude, and with a mirthful (perhaps too mirthful) expression depicted, as if enjoying the serious way in which a little child seated in the foreground is being decorated with a wreath of convolvoluses by an elder girl. The child's lap is full of lilac blossoms; and on the right hand two more little ones are seen approaching from the distance. These last-mentioned figures are somewhat too near in fact; but we have no doubt that by a little judicious management they can in future specimens be thrown further back to the eye. In the upper part of the left side of the subject a girl, with the skirt of her dress pinned up behind and right arm raised with her hat in her hand, is chasing a butterfly, while a companion at her side and a boy in the foreground are both intently watching the issue of the chase. The figure of the little huntress, whose back is towards the spectator, is extremely well designed and full of action. Some of the outlines are a little too hard. There are one or two defects from distortion, and we have admitted that some few other faults are also apparent; but, upon the whole, Mr. Robinson has done much in carrying out a happy idea, while some of the existing drawbacks are remediable in future impressions.

PHOTOGRAPHERS THEIR OWN ARTIFICERS.

By Thos. Gulliver.

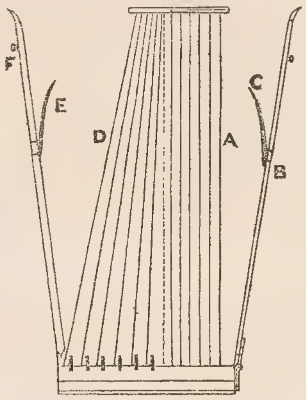
No. IV.

Improved Plate Box; Double Stereo-Camera without Dark Slide; and Improved Washing-tray.

During the past season I have constantly used the tent described by me in No. 104, October 15th, 1859, and in that time have taken upwards of 200 negatives and positives, and found it the most portable and convenient of any that have come under my notice. It has been my aim, as much as possible, to reduce the weight of the apparatus and get rid of every superfluity.

The washing-bath, with its 14 oz. of liquid, I have superseded by a light washing-tray, 9 in. long by 6¾ in. wide, and 1 in. deep inside. This requires only 7 oz. of syrup, and after washing over the plate the syrup is returned to a wide-mouthed bottle; and the 7 oz. of syrup is sufficient to wash and preserve half-a-dozen plates 8½ in. by 6½ in.

In lieu of the usual plate boxes, I have made one box that occupies but little space, and is very light. I have at present one made of wood, but intend soon to have one made of metal, in this form:—



The front compartment A will contain six plates, ready cleaned for use: they are kept in place by the spring C, and shut in clear from dust by the hinged lid B, which has a slight rim turned round the edges. The other part of the box is for the negatives when removed from the syrup bath. They are reared against the middle of the box, and two small brass points near the top keep the plates from injury: they are kept in place, at the bottom, by small brass pins about ½ in. high, at regular intervals. The lid or shutter F is not hinged, but dropped into a groove, and is fastened by a brass button. The spring E keeps the plates in place, and they travel safely, and thus all the risk of rubbing the film by sliding the plates down a groove is done away with. The bottom of the box is double, and all draining from the plates runs out at a small hole in the corner. The box would also do for dry plates, but I never use such things now.

Another encumbrance I have done away with is the dark slide and focussing frame of the camera: thus more weight than is necessary is avoided. In the old Daguerreotype times a narrow dark slide did very well, as all was to be kept as dry as possible, when collodion was made, and still continues to be made; hence a great variety of stains and failures in working wet collodion plates arose from this defective form of dark slide.

The late Mr. S. Buckle, of Leamington, made his cameras and dark slides suitable for the collodion process. The slides were about 1¼ or 2 in. thick: this allowed enough room for the wet plate to be clear of splashes. The plates themselves rested on three wood points. The sliding shutter ran in a groove about ¼ in. wide. The shutters were the same thickness: this did well for the portrait room, but for landscape photography my advice is, use no dark slide at all. I have now used a double stereo-camera all the season, and found it far more convenient than the usual form of camera. Thus there is less danger of admitting light; there is less time required to take the view; there is no need of covering the camera with the focussing cloth, so the wind has less effect upon it; the plate is certain to be in the same plane as the ground-glass; and last, but not least, there is somewhat less weight to carry.

A SIMPLE AND EFFICIENT PRESERVATIVE PROCESS.

By John Sebastian Davis.

[Read at a Meeting of the South London Photographic Society, October 15, 1860.]

The glass plate is to be covered with a good negative view collodion, and excited in the usual thirty-two grain nitrate of silver bath. Upon its removal, the free nitrate of silver is to be washed away, with an abundance of filtered river or rain water poured over its surface. The film is then to be covered with a preservative solution, containing a mixture of grape sugar, gum, and diastase, as naturally mixed in the dried grape. It is to be extracted by the following method:—Take four ounces of stoned plums, and mix them with an imperial pint of boiling water; as soon as cold strain through fine muslin; and, finally, filter through ordinary filtering paper. The washed plate is to be covered twice or thrice with fresh quantities of this extract, and afterwards gently washed in an upright bath, or in any other convenient manner. The object of the latter process is to remove the greater portion of the preservative solution from the surface of the film, without disturbing that which is retained within its interstices. The development is to be effected with—

Pyrogallic acid	1½ grains,
Citric acid	½ grain,
Water	1 fl. ounce,

previously mixed with twenty minims of a sixteen-grain solution of nitrate of silver.

The usual photosulphate of iron fluid is somewhat to be preferred in cold weather; but the negative will require to be slightly intensified with the pyrogallic developer. It is to be fixed with hyposulphite of soda, dried with a gentle heat, and varnished.

PHOTOGRAPHIC ENGRAVING OF BLOCKS, TO BE PRINTED WITH ORDINARY LETTERPRESS.

The Invention of Mr. Paul Pretsch.

We have had the pleasure of presenting our readers, in the last number of this Journal, with one of the first blocks produced by the above-named process. It was printed by steam with ordinary letterpress. However, for the sake of making the advantageous application of this process more striking to the public, we have now inserted one of these blocks amongst the types themselves.

The process consists, as already stated, in a combination of photography with electrotype. Photography furnishes the engraving of the picture in the proper and desired effect. It appears wonderful how Nature can be used and guided (it can never be compelled) to meet the requirements of technicalities—to produce the engraving just in the very same style as it is wanted. An experienced engraver, examining some of these blocks, may be misled in his judgment, and believe that some portions of them have been executed by the graver, or by some other assistance of the human hand.

The engraving produced by photography is not solid, but is transient; consequently it must be transformed into something solid, to print from. This is done by the means of moulding and electrotyping, resulting in a solid block—the face of copper, backed with type metal, and mounted on wood in the usual manner.

Our readers will easily perceive that all originals which are serviceable to photography can be used for reproduction by this process; consequently almost every subject of art or nature can be transformed into a block for ordinary letterpress, without the interference of a draughtsman or engraver. Therefore, the real touch of the artist, or the true finger of nature, will be preserved and reproduced. Science and art, the faithful followers of nature, will receive authentic illustrations, and the influence of the press, already in active power for general distribution of knowledge, will be increased. Experience and time will very soon bring to light the results, to be seen in our books, periodicals, and newspapers.

Printing from blocks by ordinary letterpress cannot be surpassed in cheapness and rapidity by another mode of printing; it is, therefore, literally the art for the million. However, for high works in the fine arts, where a few thousands of copies only are required, there is still Mr. Paul Pretsch's first process available, in which are used similar means, and results in the production of an engraved copperplate, which can be coated with iron, and printed with the usual printers' ink on the ordinary copperplate printing-press. This is called *Intaglio Printing*, contrary to the explained process of printing from blocks, or *Surface Printing*. We hope and wish that both processes may be cultivated and applied in the most extensive manner.

DOVER CASTLE.

PHOTOGRAPHED FROM NATURE BY FRANCIS BEDFORD.

Printed with ordinary Letterpress from a Block produced by Photography and Electrotype, absolutely untouched by the graver. The invention of Herr Paul Pretsch.

STEREOGRAPHS.

Picturesque Scenery of the Highlands of Perthshire, by WILLIAM RODGER, *Montrose.*

> "Then slowly climb the many winding way,
> And frequent turn to linger as you go;
> From loftier rocks new loveliness survey."
>
> *Byron.*

THERE are perhaps few localities that have been more frequently explored by the disciples of the camera than the Highlands of Scotland; and we may add that there are few that have had more justice done to the enchanting spots with which they abound. Some of our best operators are natives of the northern section of our island, and the proverbial *amor patriæ* may possibly have had something to do with the extra, we had almost said filial, care with which the more charming lineaments of their beloved land have been delineated by them. In July last we noticed some of Mr. Rodger's Tweedside views: we now come to some of his Perthshire studies. Along most of the valleys traversed by the numerous mountain streams in Scotland, the otherwise stern and rugged rock is generally clothed with a mass of fir-trees and other gymnospermous specimens of vegetation; and it is no doubt owing to the constant humidity of the atmosphere, produced by the spray from the numerous "falls" with which these streams abound, that vegetation flourishes in places where the soil would appear to be but scanty.

There is a peculiar character about most of the Scotch valleys that stamps them with an impress almost unmistakeable, although there is no more sameness than we notice in the various members of one family; and while each one possesses an individuality it is not the less distinguished by a distinct nationality.

THE UPPER AND LOWER FALLS OF BRUAR (Nos. 23 and 25) exhibit this nationality in a marked degree. In the former the deep ravine, with its steep rocky sides, is almost entirely concealed by the thick plantation of fir-trees, across the feathery tops of which the sunlight glances, gilding each with an artist's touch, while the little stream leaps from step to step of its rocky bed like a child just loosed from school. In the latter the waters have worn a deep chasm in the hard rock, in a zig-zag form, while here and there it has fairly forced away the softer subsoil, leaving a natural arch, through which it pours its ever-ceaseless stream.

THE UPPER FALLS OF MONESS, BIRKS, ABERFELDY (No. 15), is one of those scenes which once visited can never be forgotten; nor have we forgotten this, albeit we have never visited it but by Mr. Wilson's aid on a former occasion. From beneath a rustic footbridge, on which a couple of spectators are to be seen, the stream shoots out over the dark stratified rocks, breaking quickly into a light veil of foam. Here, besides the pines, we have beech and birch trees, and other frequenters of more sheltered haunts than are to be found amongst most of the Scottish hills. This is a very beautiful slide.

Of THE SECOND FALLS OF MONESS we have two illustrations (Nos. 16 and 17), each gems in their way, the former being conspicuous for the gracefully drooping branches of some gigantic fir-trees, between which the waters of the "fall" are seen in the distance, the latter for the elegant broken curve of the stream as it foams along its step-like bed.

THE HERMITAGE BRIDGE ON THE BRAUN.—This is a spot which we well remember having spent some hours at; and, although we were not fortunate enough to see it in its summer luxuriance as here depicted, yet the loss was not all uncompensated, for the rush of waters from the melting of the winter's snow was unusually fine. This is a spot which the following lines from *Childe Harold* well describe:—

> "The roar of waters!—from the headlong height
> Velino cleaves the way-worn precipice;
> The fall of waters! rapid as the light
> The flashing mass foams, shaking the abyss;
> The hell of waters! where they howl and hiss,
> And boil in endless torture; while the sweat
> Of their great agony, wrung out from this
> Their Phlegethon, curls round the rocks of jet
> That gird the gulf around, in pitiless horror set,
> And mounts in spray the skies, and thence again
> Returns in an unceasing shower, which round,
> With its unemptied cloud of gentle rain,
> Is an eternal April to the ground,
> Making it all one emerald. How profound
> The gulf! and how the giant element
> From rock to rock leaps with delirious bound,
> Crushing the cliffs, which, downward worn and rent
> With his fierce footsteps, yield in chasms a fearful vent
> To the broad column which rolls on and shows
> More like the fountain of an infant sea
> Torn from the womb of mountains by the throes
> Of a new world, than only thus to be
> Parent of rivers, which flow gushingly,
> With many windings, through the vale!"

The views from below (No. 3) and from above (No. 7) are both equally beautiful, though in neither of them is the "fall" itself, which recalled the preceding lines to our memory, seen; so vividly, however, did these stereographs remind us of the spot, that instantly the recollection of the surging waters rushed upon us in all its original freshness. The best view of the waterfall is from the window of a small building called the Hermitage, which confers the designation on this "fall" to distinguish it from another about a mile and a half higher up the stream, near to what is known as THE RUMBLING BRIDGE, of which also we have two illustrations (Nos. 9 and 10); and in viewing these we are again delighted with a flood of pleasant memories. A very ordinary-looking bridge of one small arch spans the chasm like an awful "gash" in the black rock, through which, deep down, the water hisses and boils, a small portion of it being visible in No. 10. In our opinion the best view of this spot is obtainable from the other side of the bridge; but to take it involves a rather "ticklish" bit of climbing, and the "perch," when reached, is none of the safest, being covered with a treacherous, slippery kind of moss, as we know from experience, having planted our camera thereon, somewhat to the dismay of our Scotch friend, who thought our lowland legs unfitted for the work, and felt responsible for our safety.

The best view of the "waterfall" is from a spot which we reached, also, in our friend's absence, but where it would be in vain to expect to plant a camera—being a rock in the middle of the stream, and which is only to be reached by some dexterous gymnastics, and when there, one is very speedily soaked to the skin by the copious spray which is thrown up. When at this spot we witnessed the magnificient effect of a brilliant rainbow, which appeared to form a nearly perfect ellipse from where we stood. It must not be forgotten that we are on classic ground, being in the immediate neighbourhood of "Birnam Wood," alluded to in *Macbeth*.

No. 2 is a view of DUNKELD from the old trees of Birnam. The bridge across the Tay, the old Cathedral, the principal part of the town, the finely wooded hills belonging to the Duke, are all included in the picture.

DUNKELD CATHEDRAL is a ruin possessing no particular architectural beauty; but, overgrown as it is with ivy, and taken with its picturesque surroundings, it is a very attractive subject for the photographer. We scarcely think Mr. Rodger has been as judicious as usual in his selection of a point of view with regard to this slide—not, however, that we have aught to object to what is before us, but we remember to have found a better one, close to a summer-house on the further side of the bowling-green, in the Duke's ground, from which not only the whole of the cathedral is included, but in addition a couple of magnificent trees, which add much to the artistic value of the subject.

BISHOP CARDNEY'S TOMB, in Dunkeld Cathedral, is admirably rendered, in a style to give satisfaction to the artist as well as to the antiquary. Being unaquainted with the correct antiquarian "slang" in which to describe this particular kind of tomb, we can only state that it consists of a slab, on which reposes the time-worn remains of a recumbent sculptured figure, in an arched recess in the wall of the edifice. On the left is a gothic window, destitute of glass, through which the stem of the ivy has found an entrance from the outside, the branches of which serve to adorn the mouldering walls. The floor consists of a few flat stones recording spots sacred to some memories, now, alas! no longer remembered, between which the rank grass and a few small tree-shoots find their way towards the light. On the left is a stone pillar possessing no beauty of its own, but glorified by the chequered sunshine streaming in from the opposite window.

Such are a few of the beauties of Bonnie Scotland—a most appropriate designation by the way—to which Mr. Rodger introduces us; and, whether regarded as records or as works of art, they are equally interesting.

INSTANTANEOUS PHOTOGRAPHY AND COMPOSITION PRINTING.

[Read at a meeting of the South London Photographic Society, 15th November, 1860.]

By SAMUEL FRY.

IN the midst of our discussions on dry processes—the failure of one, the success of another, and the peculiarities of a third—it may not be amiss to halt a moment and consider certain advantages pertaining to the wet collodion process in its most sensitive form. I consider it an error of judgment on the part of those who would utterly repudiate either method of manipulation in favour of the other, as each has, beyond doubt, great and manifest advantages for its own class of subjects; and I trust to be able to show you this evening, to your satisfaction, that whilst, as at pre-

sent constituted, wet collodion has unquestionably the most rapid action, and produces more atmosphere as a rule, that it is far from hopeless to expect that ere long we may be able to prepare dry plates capable of producing all that wet collodion now does.

I have also in view, in troubling you with this paper, to impress on photographers the primary importance of introducing artistic feeling and true *chiaroscuro* into our landscapes, &c., rather than making that incubus of the art, sharpness, take the pre-eminence.

The mass of chalky white sky is a great fault in a fine landscape, and I have brought a few specimens to illustrate the improvement easily obtained by the very simple operation of printing in a cloud sky from a second negative. I will also explain the method I adopt of taking from nature these cloud negatives, and adjusting them to various subjects.

I may perhaps commence by describing the chemicals and apparatus used by me for taking instantaneous stereoscopic and other negatives of the waves of the sea, copies of which are now in the stereoscopes before you, and also other large pictures on the table.

In making the bath I use crystals in preference to fused nitrate of silver, and choose always a sample which has no perceptible odour of free nitric acid, as that would of course tend to retard the action. I consider the bath should certainly be of the strength of forty grains to the ounce, and I have frequently, with advantage, used it with as much as fifty, but there is with this strength a considerable inclination to attack the plate when kept for more than five minutes. I keep this bath carefully neutral, in fact, I have frequently, adding acid in proportion to the developer, had it with a slight alkaline reaction; but I do not recommend it in this condition, as being most difficult to manage, the slightest *soupçon* of diffused light in the camera or dark-room being enough to cause fogging. The collodion I prefer is that sold for positive photographs, and there are so many excellent makers in the market that it would be invidious to specify any particular maker; but I strongly suggest it should be mixed not more than a week before using. Negative collodion may of course be used with perfect success, but most samples so rapidly lose their normal sensitiveness that I have found more difficulty in obtaining the best results with it than with positive. Of the pictures now before you, the one taken with the shortest exposure is that numbered 2, the ground-swell, in which the breaking wave has thrown water high into the air, each transparent drop being accurately rendered in the photograph, and was done with Mr. Hardwich's collodion from a sample he prepared expressly for me; but the same collodion failed to produce an equally good result when mixed twenty-four hours, and I may say that having tried the negative collodions of the best makers, I am inclined for this special work to prefer a positive one, as being thinner, and thus giving a peculiarly smooth, even film, free from spots and blemishes, and, above all, more sensitive when developed with iron, which I generally use. It will occasionally occur when the light is not particularly brilliant that an iron negative will refuse to gain intensity on applying the subsequent negativing pyrogallic solution; but such is not, I think, frequently the case: when it is, I have used, with much success, first a saturated solution of bichloride of mercury, and when equally whitened, wash and use a weak solution of hydrosulphide of ammonia, which gives a yellow image possessing much more printing power than a cursory inspection would lead one to suppose. Samples of such negatives are on the table, though in these the final solution of hydrosulphide of ammonia being too strong, they are almost too dense to print well.

A binocular camera is on the table which has the interior arrangement of shutters I prefer and use for instantaneous work: by the slightest imaginable movement of finger and thumb the exposure is achieved. I am a sceptic with regard to those fabulously small fractions of a second in which some would have us believe exposures are made and pictures taken, as I find much rougher methods of exposure even than those before you perfectly practical in taking objects in motion. In a recent letter from Mr. Wilson, of Aberdeen, whose charming works we all know, he tells me he covers his lenses with his own Scotch cap, and simply lifts it off and on again. If such simple means are so successful for obtaining good pictures, surely there can be no advantage in having any of the costly and complicated affairs which have been recommended in the way of sliding shutters, which are almost certain to stick at the critical moment from damp, or else they shake the camera in moving.

I have invariably used a pair of double lenses, made for me by the late C. Shepherd, and think them equal, at least, to any made by far more expensive makers.

I place a stop of 3-16ths of an inch between the lenses, which will bring foreground and horizon into perfect focus.

The iron developer I use is—

Iron	20 grains.
Ac. Ac. Beaufoy	1 drachm.
Ac. soda	1 grain.
Aq. dist.	1 oz.

I pour a considerable body of this in one sweep over the plate, and let it develop the picture as far as it will, sometimes adding a few drops of a fresh solution of nitrate of silver, not having any iodide in it. I then carefully wash the plate with a good stream of water, and proceed to densify with

Pyrogallic	3 grains.
Ac. Ac. Beaufoy	1 drachm.
Water	1 oz.

or—

Pyrogallic	3 grains.
Citric acid	1 grain.
Water	1 oz.

As a general rule, I can at once obtain sufficient density on adding a few drops of the above-named solution of new nitrate of silver; but when it fails I use, as hinted before, the bichloride of mercury, followed by hydrosulphide of ammonium.

I conduct the intensifying in daylight, but not in strong light.

I will now speak of three small paper photographs before you, representing sea, and clouds, shipping, &c., also moving figures on the land: these were done with dry plates, prepared by Taupenot's method. I wish I could say they were by Fothergill, which I must prefer for its certainty of result and simplicity; but I confess I have not yet succeeded in producing quite the same degree of sensitiveness in this latter, though from recent experiments I am persuaded it is to be done, and intend next season to pursue it. They perhaps scarcely fulfil the desired conditions of instantaneity, being done with a ¼ Ross lens, double combination, and stop of two inches; but the exposure was undoubtedly sufficient, and proves that more is to be done in that direction. The clouds are printed in four different negatives, and add very greatly to the general effect; and I will now describe the means I use for taking the cloud negatives, some of which are in the room.

If for the previous operation the highest possible sensitiveness is required, here we have the very reverse, and I therefore use old port-wine-coloured collodion, an acid bath, and a long focus landscape lens, and a weak developer. The exposure is generally nearly instantaneous, and it suffices perfectly to cover a cloth over the lens and lift it during exposure.

To develop I use half a grain of pyrogallic acid, 1 drachm of acetic acid, 1 oz. of water, and bring it up very slowly: by this means very admirable clouds are produced, possessing wonderful half-tones, and yielding every shade from intense white to black. I usually take the cloud negative not larger than 5 × 4, then print a transparency on a Fothergill plate, and enlarge that up to 18 × 15. In the enlargement it gains in detail, and acquires exquisite softness and beauty, and from a negative of that size may be printed different skies into twenty or fifty other pictures: each portion of sky may, by judicious printing, be made to yield different characteristics suitable to the subject to which it is joined.

I will in a few words explain my method of composite printing, as shown in the circular picture, *The Break in the Clouds*, and also *The Heavy Sea at Brighton*, now before you: the latter picture is printed from three negatives, which I have here. The first to be printed is the foreground of boats, and whilst this is in the frame, a mask of cardboard, cut roughly to the shape of the upper edge of the negative, and edged with cotton wool, is laid outside the pressure frame, over that part of the prepared paper which is intended to be kept white: the frame with the mask in it is then placed in diffused light. To examine the printing, I invariably bring the frame into the dark room, or the pure white of the picture will be degraded: when this part is sufficiently done, I take the sea negative, and which has a light paint mark on the lower part, corresponding with the outline of the previous plate. The plate being laid on the paper in proper position, as shown by this line, has two masks superimposed on it: the lower one covers the part already printed, and the upper that reserved for the sky. Again the frame is exposed to light until the central strip of sea is printed; then the cloud negative is placed on the paper, and a mask covering both the lower parts is placed in position. The operation is much more simple in reality than in description; and, if ordinary care be taken, no part of the picture can overlap the other. By this means highly artistic effects are produced, such as can scarcely be obtained in a simple negative. I will now say a few words with respect to printing clouds into architectural and landscape pictures, which I do by making lightly on the back of the cloud negative a line corresponding with the outline of the picture: the two are then placed in the frame, and a mask placed over the landscape or building already done; the cotton wool at the edge of the mask and the thick glass of the pressure frame combine to prevent any hard line round the picture.

I have to thank you for the kind attention which you have given me; and though there are many present to whom anything I have read to-night must be perfectly well known, still I trust that the discussion raised upon points I have alluded to may not be without its advantages.

A PHOTOGRAPHER'S HOLIDAY IN DERBYSHIRE.

By D. W. Hill.

[Read at the Meeting of the North London Photographic Association, October 31, 1860.]

It has more than once been remarked, that in the absence of any definite instruction in matters photographic, a mere detail of the failures, successes, and experiences generally, of almost any photographer, will always furnish material for profitable discussion at our meetings; and, understanding that there is no more important subject to engage your attention this evening, I have been induced, at the suggestion of one of our members, to lay before you a short account of my own fortunes while seeking a renewal of health and recreation in Derbyshire, during the month of July, in the present year—a selection of time which I cannot but regard as fortunate, seeing that the almost uninterrupted wet

weather of necessity almost put a stop to photographic operations, out of doors at least, while the first fortnight of the month in which I took my holiday proved as fine as could possibly be desired.

I started on the 5th, taking with me my stereoscopic apparatus, and Burfield and Rouch's dark box, with a good supply of chemicals for the wet process. Just before arriving at Matlock it began to rain, but cleared up in the evening, and remained fine for ten successive days. In order not to lose any time I commenced operations the next morning after my arrival; and as I had not previously used the dark box, I had to familiarise myself with the method of working in it.

The weather being warm, I found much difficulty in developing when employing Ponting's collodion, as I could not cover the plates evenly before the action commenced, although I increased the amount of acetic acid. But Bolton's collodion I found worked admirably; it developed slowly, evenly, and without fogging—a quality which accounts for its being so much esteemed in Natal and India. In cold weather I prefer Ponting's, or a mixture of that with Bolton's.

I found the dust very troublesome, and was obliged to keep the inside of the box damp. After the first day's experience I rarely failed in getting clean negatives; and I can strongly recommend those who very naturally object to being suffocated in a tent to try one of the boxes introduced by Messrs. Burfield and Rouch.

Matlock and its neighbourhood contain, within a small compass, more good subjects for the camera than any place with which I am acquainted: you cannot go a dozen yards without seeing something worth taking. It consists of three portions—Matlock Village, Matlock Bank, and Matlock Bath. The village has no particular object of interest but the church, which is decorated (!) with a very grotesquely-painted ceiling.

The Bank is identified with Mr. Smedley's hydropathic establishment, which is decidedly not ornamental, resembling outwardly a workhouse or factory. The walk from the "Bank" to the "Bath" is, however, most lovely. After crossing the bridge, some bold masses of rock, called "The Church Rocks," first attract your attention. Following the course of the river Derwent you come to the railway bridge, from which there is one of the finest views of Matlock Dale. Leaving the Boat House Inn on the right you come to some quarries, one of which requires some caution in passing, as, from the careless mode of blasting adopted by the workmen, large blocks of stone are frequently blown across the road into the river. At the back of the Boat House the rock is almost entirely composed of fossils (some of which are very fine), and is used for making mantelpieces and the other fire-place appendages. Close to this spot I took a picture, including quarries, boat-house, bridge, &c., with Matlock Bank for the background.

A little beyond this is a tollbar, from which a splendid view of the High Tor, the most striking object in the immediate neighbourhood, is to be obtained. It is a stupendous rock, 400 feet high, rising almost perpendicularly from the water's edge, and covered for two-thirds its height with trees and underwood in picturesque confusion. I took several views of it from different spots. Nearly opposite is another hill, called Masson *Low*, which is, I believe, the highest ground about Matlock, and is nearly thrice the height of the High Tor, being 1160 feet above high-water level.

About half a mile farther on from this spot the road takes a sudden turn to the right, and brings you to Matlock Bath, with its villas studding the side of the hill—the caverns, obelisks, church, lovers' walks with their rich masses of foliage—affording subjects enough to satisfy the most enthusiastic follower of our art. The scenery between this and Cromford is very fine, but, in my opinion, not equal to the other side. Near Cromford is Willersly Castle, the residence of Mr. Arkwright, which is very beautifully situated. Going through Cromford, I took a steep footpath which led to a miners' village, called Bonsall. On a fine day many very pretty pictures of the "hollow" might be taken; but on the day when I was there a mist obscured the distance; so I only tried two, which would have been much better but for that cause.

From the unusual curiosity shown by the people at Bonsall, I should think it had not often been visited by a photographer. I was quite mobbed, and prevented taking many pretty spots which I had selected. I succeeded, however, in securing the old Market Cross—a pillar, dated 1678, resting on a base formed by an ascent of ten steps.

When the children saw what I was about, they crowded up the steps, and I made an attempt to take them in that position, but just as I had uncovered the lenses, an unfortunate rat running across the road caused the whole of them to start in pursuit. While I was occupied in taking the Cross, a lad, who accompanied me to assist in carrying my apparatus, amused himself by inducing some of the boys to dip their fingers in the waste developing solution and then rub them on their noses, which under the influence of the light soon assumed a piebald appearance, decidedly more comical than elegant, and no doubt astonishing to their affectionate relatives, for I rather imagine they were puzzled to get the stains off. On another occasion, as I was fixing a plate, my factotum informed some people that I was "taking the scum off," fancying, of course, that in his "distinguished" position it would not do to appear ignorant of the object of any of my operations.

Having become tolerably accustomed to my box, I one morning took the train to Rowsley, and from thence proceeded to Haddon Hall, which is considered one of the finest and most perfect specimens of an ancient baronial mansion in existence, and forms a marked contrast to Chatsworth, which represents the modern style. Both places are generally visited on the same day.

Haddon Hall is situated on an eminence, on the banks of the Wye, and is seen best when approached from Rowsley; it belongs to the Duke of Rutland, and, though not inhabited, is kept in good repair.

Having secured six or seven negatives, I made way for a gentleman who had a small cistern about four feet square, mounted on wheels, for a dark room. He also was taking stereoscopic pictures.

I then proceeded to Bakewell to take the ancient Saxon Cross in the churchyard. In the church, which is a magnificent structure, are some very curious Druidical and Saxon remains, large numbers of which were found when the church was renovated. There are also some very handsome monuments to the memory of members of the Vernon and Manners family, which I should have attempted but for the circumstance that Divine Service was being performed.

While looking for the best point of view, I stumbled on two epitaphs, which I will venture to repeat. The first was to a defunct parish clerk, and had the following lines:—

> "The vocal powers, here let us mark,
> Of Philip, our late Parish Clerk.
> In church who ever heard a layman,
> With clearer voice say Amen?
> Who now with Hallelujah sound,
> Like him, can make the roofs rebound?
> The choir lament his choral tones;
> The town, so soon here lie his bones.
> Sleep undisturbed within thy peaceful shrine,
> Till angels wake thee with such notes as thine."

The other was as follows:—

"Know posterity, that on the 8th April, in the year of grace 1757, the rambling remains of the abovesaid John Dale were laid on his two wives.

> "This thing in life might raise some jealousie;
> Here all three lie together lovinglie.
> But from embraces here no pleasure flows,—
> Alike are here all human joys and woes.
> Here Sarah's chiding John no longer hears,
> And old John's rambling Sarah no more fears:
> A period come to all their toylsome lives;
> The old man's quiet—still are both his wives."

On the following day I went to Chatsworth, the seat of the Duke of Devonshire, which I shall not attempt to describe, as to form an idea of the magnificence of this Palace of the Peak, its contents and grounds, it must be seen. I was not so fortunate as on the previous day. A thick fog came on and increased till I could see nothing on the ground glass. I had, however, taken a view of the bridge, with a portion of the mansion beyond, and one of the entrance gateways, when I was obliged to give up, and went to see the model village of Edensor, which consists of an old Gothic church, handsome fountain, and cottages built in the Elizabethan, Swiss, and almost every style of architecture but the one usually adopted by villagers.

My last trip was to Wingfield Manor. The morning was dull, but not sufficiently so to deter me from going. When I arrived at Ambergate, it rained heavily, and only held up while I walked from Wingfield Station to the Manor, when it poured in torrents, and continued to do so till I left. This was not exactly what I wanted; but having come a long distance, and it not being likely I should have another opportunity, I determined not to go away without some reminiscence of the place. So I borrowed a tarpaulin from the farmer who resides there to cover my box, and set to work, and succeeded in taking seven negatives of objects near, the exposure varying from four to six minutes.

The manor was built in the reign of Henry VI. During the civil war it was twice taken, first by the Royalists, and afterwards by the Parliamentary forces, when it was dismantled. Mary Queen of Scots was imprisoned here for some time; and at the village inn they show a piece of the bedstead supposed to have been used by her. There is a fine old crypt in very good condition, and said to be only equalled by the one at Fountains Abbey, and from the principal tower on the south side there is a very beautiful and extensive view. In fact, I consider it one of the most lovely ruins I ever saw, and, notwithstanding the rain, I was not dissatisfied with my day's excursion.

During the latter portion of my stay it rained almost incessantly, preventing my going to Dove Dale, Lea Hurst (the residence of Miss Nightingale), and various other places I wished to visit. However, if every one has had as pleasant a trip this summer as I have enjoyed, they will not have much reason to complain.

I usually took with me two three-ounce bottles of collodion, six ounces developer, four ounces cyanide solution, a gutta-percha bottle holding a quart of water, a smaller one for rinsing the plate before fixing, two pneumatic holders, one dozen plates in light box with wide grooves, and gutta-percha bath, which was always annoying me by the covers sticking and having to be torn off. I used up three of them. I had a fluted glass dipper, which I like very much, as the plate cannot slip off.

In conclusion, I have only to request your indulgence for any shortcomings of which I may have been guilty in detailing what you may possibly regard as a very commonplace account of my photographic wanderings; my desire being to communicate to you some portion of the pleasure that I myself experienced in the trip, and, if possible, to open up a vein of profitable discussion, whether as regards the respective merits of tents, boxes, dry or wet plates, or anything by which amusement or information may be found. Should I have entirely failed in my attempt, I can only beg you to excuse me, and to "take the will for the deed."

NOTES OF A PHOTOGRAPHIC YACHT VOYAGE IN THE MEDITERRANEAN.

By W. J. C. Moens.

[Read at the North London Photographic Association, 28th November, 1860.]

Having recently returned from a voyage of nearly a year in the Mediterranean, during which time my friend (who had kindly asked me to accompany him in his yacht) and I took photographs in most of the places we visited, and fell in with numerous followers of the "black art," both professional and amateur, I feel it my duty, as a member of this Society, to give you my experience of the enjoyment, difficulties, and troubles, all of which are encountered in turn by the photographer when he leaves his dark room at home—the light and temperature of the country in which he has gained all his knowledge—and goes to wander from place to place abroad, in each of which difficulties arise which must be overcome before he can get satisfactorily to work. This is one reason why, out of the number of travellers who take photographic apparatus with them, so few return with good pictures. Professionals, on the other hand, from residing some time in a place, and nearly always using some dry process, get results which the amateur, in his hurried visit, finds a difficulty in obtaining.

I think it will be interesting to you to know what apparatus we took out with us to work the wet process. Tents I always considered an abomination. Burfield and Rouch's box for the sized plates we proposed using, viz., nine by seven, was so large, and when stowed with bottles, plate boxes, &c., inside, would not bear being shaken up on the top of a Spanish diligence, or slung on the side of a mule or horse, without the breakage of half its contents. What I wanted was a box which, when shut up, would hold my large and stereoscopic cameras, nitrate of silver bath, two dozen glasses, the necessary bottles, &c., and a little box of spare chemicals, and which would be sufficiently strong to bear any description of transport, and not large enough to allow all the contents to be shaken into a jelly.

The box which I have here is one which I contrived after much thought: it was made for me by Messrs. Bolton and Barnitt, of Holborn, who have the pattern. I can strongly recommend it as most convenient for working with wet collodion. It contains all the apparatus required, can be easily carried, and very quickly put up and taken to pieces.

I must now go back to the subject of my paper. We made our departure from the Start at 10 o'clock, p.m., on the 5th October, last year, and steered W.S.W., with a fine breeze, straight for the coast of Portugal. On the 11th, after enjoying all the delights of strong winds and calms, with a heavy sea in the Bay of Biscay, we sighted the Burling Islands, distant about fifty miles from the Rock of Lisbon, for which port we were bound. Fate had ordained that we should suffer all the miseries of a gale of wind before reaching land. We were hove-to for the whole of two days, the wind blowing right into the mouth of the Tagus, which is full of the most dangerous sandbanks, with only two channels sufficiently deep for the entrance of vessels. The clouds and rain rendered it too obscure for us to see the various landmarks necessary for steering our way between the sands, and the sea was so high that no pilots could come off to us. On the morning of the 13th, after two trials, we followed the P. and O. steamer, and were soon flying before the wind, in smooth water, up the river Tagus, which is about the same width as the Thames below Gravesend. We soon passed Belem Castle, the forts of which the French once knocked to pieces, when they paid a visit to Lisbon. We saw a magnificent church a little farther on, and promised ourselves a photographic visit to it as soon as possible. At about two o'clock we arrived at Lisbon, which is a very large city, built on high land, rising from the water. The houses are painted red, green, blue, and white. It has a very noble appearance from a distance; but, when you are close, the houses look mean and poor.

On Saturday, 15th October, the weather appeared more satisfactory, and we looked out our cameras, boxes, &c., and made new nitrate baths. The following Monday it rained all day, so we amused ourselves by cleaning glasses, and getting everything ready to pass the Custom-house. To do this we had to procure about twenty-five signatures to various special permissions, and, besides this, to pay a deposit of about £6 duty, and find security for £50, to ensure of our not disposing of our apparatus in Portugal. A friend in the customs' department kindly assisted us; but even with his aid it was late in the afternoon before we deposited our boxes in the Hotel Central. On Wednesday, the 19th, we rose at half-past five o'clock, with a violent photographic fever on us; got two Galligos (Spaniards from Gallicia, who act as water-carriers and porters to the Portuguese, who are too proud to carry the smallest parcel for themselves), and climbed with our things to the top of the castle St. George, which is the highest point in the town, and commands magnificent views all round. After hard work we arrived at the top at seven o'clock. To our great dismay we found that the Governor would not be up before ten; but, by continually sending up to him, we got permission to take possession of a battery at about half-past eight. We soon got to work: my friend with one of Horne and Thornthwaite's tents, and I with my box—each having one of the yacht's men to assist us. We found the light so intense that it gave us a great deal of trouble, and we were not very well satisfied with our morning's work.

I commenced with forty seconds' exposure, and found that twenty was sufficient, the focal length of my lens being about fifteen inches. We obtained water from a Galligo, who delivered over a barrel and contents for the sum of threepence, engaging to fetch the barrel when we had done with it. I found the "legs" of the dark box rather too long; so, on returning on board, I shortened them with the assistance of our carpenter.

On the 23rd we started for Cintra in a carriage—a drive of about fifteen miles. The first part of the way was very uninteresting: the fields were quite bare, the only vegetation being hedges of aloes and prickly pears, and a few dusty olive trees. The leaf of this twisted, ragged tree is very like that of a willow, but rather shorter and darker. The mountains on which Cintra is situated look very imposing as you approach them, covered to the top with firs and cork trees, and crowned with castles. We put up at the Victoria Hotel, which is kept by an Englishwoman; and the next morning got up early, procured a donkey with a large pannier on each side, in which we packed our paraphernalia, and began to ascend the mountain. Half way up we took pictures of the *Moorish Castle* and *La Peña Palace*, which bear evidence of the Mahomedan rule in this country. We then went to the top, and took sundry other views, whose only recommendation was their beauty; but this was the first and last time we took pictures unless they had something special to recommend them. The light was much more manageable to-day, and we got on pretty well, the exposure being from a minute to a minute and a-half, or about three times as long as at Lisbon: there was some amount of moisture in the air here, which I always found made a great difference, so much so, that I frequently used to consult the barometer before starting. The view from the tower of the Palace was exceedingly beautiful. All round the mountains in the foreground are covered with fir and cork trees, with enormous boulders of stone scattered *everywhere about*. The country below is spread out like a map: in the north, mountains in the distance bound a fertile plain; in the west you see Fort St. Julian, the mouth of the Tagus, with the waves rolling in from the Atlantic, breaking on the bar, and farther on the coast line, terminating with Cape Espicial; and to the east the vast city of Lisbon, and beyond that the mountains of St. Ubes.

The next day we telegraphed for a carriage, and got back to Lisbon at eight in the evening, delighted with our trip. On Wednesday morning we printed the pictures we had taken, and in the afternoon rowed down the river to Belem, in order to take the church we had noticed when sailing up the Tagus. It was that of St. Geronimo, built in honour of the discovery of the Cape of Good Hope, by Vasco de Gama: the sacristy and cloisters are particularly beautiful. We soon found out that buildings are far easier to take than distant views. It was a fine clear day, and the exposure at half-past three was one and a quarter to one and a half minutes.

On Friday, the 28th October, having got tired of Lisbon, we paid farewell visits to our friends, and sailed for Cadiz. We passed the bar at half-past three—a very different scene to what it was when we entered—the water quite smooth, and a fleet of thirty or forty little fishing-boats, looking very quaint, with their outrigged sails of every size and shape sticking out all round them; some had even square sails at the end of their bowsprits. We soon got out into the long north-west swell, which we did not lose till we rounded Cape St. Vincent, when the Atlantic, nearly always in a high state of commotion, became as smooth as a duck-pond, with hardly a ripple on it. On Monday, the 31st, we cleaned glasses, which was always a source of amusement when wearied by the monotony of a calm. We sighted Cadiz in the evening, and the next morning brought up off the town. There was nothing very particular to photograph there; and, not being able to find an interpreter, we sailed the next day for Gibraltar. As soon as we had passed the ever-memorable Bay of Trafalgar, we stood over to Tangiers, which the Spaniards were blockading: the Vulture and a French steamer were in the Bay, and the Spanish gunboats were firing at the Moorish forts. The mountains on each side of the Straits looked magnificent. The rock of Gibraltar is not visible till you have passed Tarifa Point. The wind was very light, which prevented our getting in till the next morning, when, having been woke early by the captain, a splendid sight was presented to our eyes. On coming on deck we found ourselves in the middle of the English fleet, consisting of eleven ships of the line, besides corvettes and gunboats: their boats were rowing about in all directions, with pretty little midshipmen in charge. We found we were allowed all the privileges of a man-of-war, and moored close under the new mole. But to our great horror we discovered that photography was strictly forbidden at Gibraltar, Sir William Codrington telling us, on our applying for leave, that if he allowed us, the French and Spanish consuls would immediately have particular private friends for whom *they* would wish to get leave, so that he felt obliged to refuse us.

We went over the galleries with Mr. Lee, R.A., who was also a photographer and a friend of the Governor's; but he too had to forego his pictures. The town was full of refugee Jews from Tetuan, to the number of some thousands: the greater number were encamped on the neutral ground, and had rations of meat and bread found them by our government. They were tall, fine men, not like the members of their race here, but with fine regular features, and the women very good-looking, with very picturesque costumes, many wearing the burnous. We spent a pleasant fortnight here, meeting with all the hospitality for which our military and naval stations are so renowned. During this time we rigged up another dark box for my friend, who found his tent too inconvenient from the heat and wind.

(To be continued.)

Letters to a Photographic Friend.

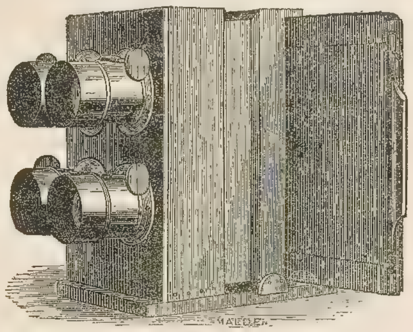
No. IX.

My dear Frank,

I have now to tell you of the novelties that came under my notice on the day that I took my last glance at matters photographic in and about London, and also to answer the questions you conveyed to me in your last communication.

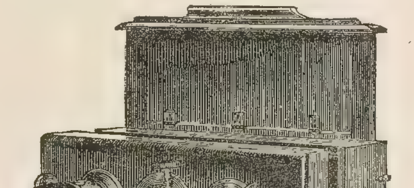
When I called on Mr. Hughes, of Oxford Street, on a former occasion, he had "something" in embryo, but that *something* was not hatched. So to him I went on my last day, and then found that he had brought forth a numerous and flourishing progeny of *carte de visite* cameras, with a slight cross of the stereo. palpably marked on their physiognomy.

In Lake Price's book you will recollect that there is the figure of a camera with four lenses, so that four portraits may be taken simultaneously in one plate. Mr. Hughes has modified this form, so that by a "repeat" arrangement eight card portraits are taken on a plate ten and a-half by eight and a-half inches. One-half of the plate frame is passed in with a lateral motion, till stopped at the point of adjustment by a spring, as in a single lens stereoscopic camera; one-half of the shutter is then withdrawn, and half of the plate is exposed to the action of the four lenses, which are then uncapped and capped simultaneously. On the shutter being pushed back, the other half of the plate is brought into position, and the operation rapidly *repeated*. The interior of the camera is divided by diaphragms into four compartments—the lower ones having greater space allotted to them than the upper pair, to allow for the lower part of the plate, usually stained by drainage, being kept out of the available field. The annexed sketch will make the arrangement more comprehensible.



Another form is arranged so that a stereo-camera may also be used for visiting-card portraits. This is nothing more than a twin-lens camera, *only* the plate, instead of being of the ordinary stereoscopic size, is equivalent to two quarter-plates, the two portraits being taken simultaneously. This is palpably a very good arrangement for amateurs, as the portraits may be mounted either as visiting-card portraits or as stereographs, as desired.

An extension of this arrangement, as shown in the following sketch, consists of three lenses placed in a row, to be used with a plate twelve and a-half by ten and a-half inches, in a frame having "a repeat" motion in a vertical instead of a horizontal

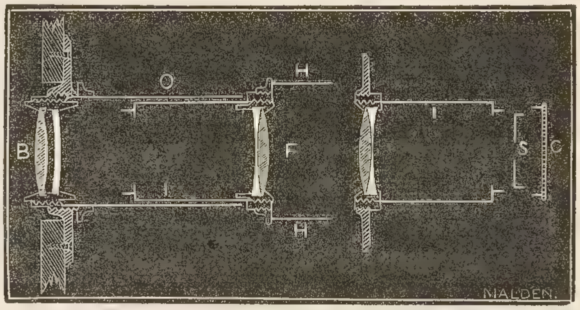


direction, as in the four-lens camera. By this contrivance three portraits are taken by one exposure, and six on one plate, which may be used either as card-portraits or stereographs—a more stereoscopic effect of course being produced by selecting the outside pair for stereoscopic purposes.

Mr. Hughes has lately made a peculiar form of stereoscopic camera for Russell Sedgefield, to be used either with view or portrait combinations. This consists of a camera with a pair of lenses, one being placed over the other if views are to be taken, the plate frame being double the size of the back of the camera. The two first counterpart views are taken, and the lenses covered; the camera is then moved over a desired angle; the second portion of the plate frame is then by a horizontal motion brought into position and exposed: thus duplicate stereoscopic views are obtained on one plate, and at the same time. If, however, portraits or groups of living objects are to be obtained, the camera is then turned over on its side, the lenses being at such a distance apart as to be in position for taking *twin* views *simultaneously* or instantaneously. This is a very handy arrangement for a travelling stereographer accustomed to work large plates.

My attention was also called to a camera-stand to be employed in the operating-room. This was made in pollard oak, the table-pillar being raised or lowered to the required height by an Archimedean screw acting on a cog-wheel and rack. Another screw motion caused the back of the table to be raised or depressed, so as to allow of the camera being inclined as required. A clamping screw rendered the whole arrangement perfectly rigid. I was struck, not only with the efficiency of this operating-room stand, but also with the very moderate price at which it is to be supplied.

Ere this you will have read in the last number of The British Journal of Photography a paper by Mr. Hughes on the various methods of mounting lenses [see p. 330]. When this was read before the South London Society, the president wished the author to give a "summing up" of the respective merits of the various contrivances; but this he declined doing. Now, you know the saying, that *a certain class* "step in where angels fear to tread;" so I will give you my ideas as to a good form of lens mount. In the first place, I own that I should prefer having my portrait and view lenses distinct, if I wished to secure *the best* optical results; and this opinion is founded on a conversation I once had with the late Andrew Ross. But we also know that very efficient lenses *are* obtainable, wherein the front combination of a portrait lens may be employed as a view lens; and such an arrangement, wherein a view and portrait combination is contained in the space of an ordinary lens mount, is certainly very convenient to the travelling photographer, especially for stereographic work. Well, then, I would have such a lens mounted thus:—



In the first place, each of the lenses in the back combination, B, should be burnished into their respective cells; so that when they were separated for cleaning they could not by any possibility be reversed. The lens cell would screw into an outer tube, O, which should screw *directly* into the flange; for I would dispense with a rack and pinion-fine adjustment, and consequently with "the jacket," now that cameras can be focussed from the back by means of an endless screw. The front cemented combination, F, should screw into the end of a tube, I, that should fit accurately, easily, and smoothly into the outer tube, O. At the end of the inner tube the various-sized diaphragms should fit; so that when using the lens as a portrait combination, by simply drawing out the inner tube, any-sized stop could be fitted into the end of it, and then it could be pushed in "*home*." When this arrangement has to be used as a landscape lens, it would only be necessary to unscrew the outer tube from the flange, pull forth the inner tube, unscrew the hood, and the male screw of the inner tube, on to

which the hood fitted, would then screw into the flange; so that the front lens in a reversed position would act for views, and any suitable stop, S, could be fitted in front of it, together with a separate "cap," C.

You will perceive that this is nothing more than a combination of some of the best points in Ross's, Jamin's, and Millet's arrangements.

Mr. Hughes has just introduced a dead black varnish, suited for backing glass positives, or stopping out skies, &c., in negatives, which has the advantage of not cracking. It may also be used for blacking the insides of cameras, lens mounts, &c., where a *dead* black is required.

On leaving Mr. Hughes's I stepped across the road to M. Bourquin's, in Newman Street, to look at some very nice camera stands suited for operating rooms, all the requisite motions being effected by powerful iron racks and pinions, the woodwork being in walnut. Some of these were very handsomely "got up," whilst others, of more homely appearance, retained all "the points" that would be looked for by a professional photographer, in the same way as a jockey looks to a horse.

Having got thus far in the description of my last day's photographic sight-seeing in London, and having much more yet to say, I must defer its completion till tomorrow, when you shall have a few more "last words" from

Dear Frank,

Yours, sincerely,

SIMEON HEADSMAN.

Meetings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting was held on Thursday, the 15th ult., at St. Peter's School Rooms, Walworth,—the Rev. F. F. Statham in the chair.

The minutes of the last meeting were read and confirmed.

Mr. Wall exhibited specimens of photographs by Mr. Wilson, Aberdeen.

The Chairman said the proceedings for the evening were to have been commenced by a discussion upon Mr. Clark's paper read at the last meeting, *On the Photogenic Action of Colour;* but he regretted to say that Mr. Clark was unable to attend, although he had sent a letter, which would be read by Mr. Wall.

Mr. Wall said before he read that letter he must inform the members that the experimental committee had commenced their labours by experimenting upon the dry process, to endeavour to find out whether they could approach instantaneous photography by that method. Several interesting experiments had been performed from which important results might be expected; but at present none of them were sufficiently far advanced to be brought before the meeting. At their next meeting a very interesting paper on the subject would doubtless be read by Mr. Hannaford, the Secretary of the Committee. In The British Journal of Photography of that day there appeared a few short remarks upon Mr. Clark's paper by Mr. Shadbolt, a member of their Society, who, doubtless, for good reasons had not hitherto made his appearance among them. Mr. Wall proceeded to read the article in question, which appeared in page 325 of this Journal, and then read the following letter from Mr. Clark in reply:—

Shooter's Hill, November 15th, 1860.

Dear Sir,—Will you kindly refer the Society to an article in The British Journal of Photography of to-day, in which the Editor calls my attention to "certain considerations" which have escaped my notice, and which will certainly heighten the value of the paper by being made known. In the first place the Editor notices the fact of my not "mentioning what sensitising materials were employed," and more particularly refers me to my last experiment, viz., the difference in the action of light by transmission through different coloured glasses on albumenised paper and collodion, and asks if the materials "were identical in both cases." My answer is, they were not; the albumenised paper was sensitised in a solution of nitrate of silver as usual, of the strength of eighty grains to the ounce, whilst the collodion was iodised chiefly with the iodides of potassium and ammonium, with a slight trace of bromide, and sensitised in the usual negative bath. The whole of the experiments referred to in my paper were made with the same collodion and bath, whilst the light in each case was (as nearly as could be guessed), of the same intensity. Reference is also made as to "the nature of the colouring matter employed." Of this I can say little, for I merely ordered the glazier to send me some strips of different coloured glasses, such as is commonly used for windows. The substances employed in the manufacture of this glass I am unacquainted with, although possibly this information might be obtained; and as I intend giving this subject further consideration shortly, I shall feel great pleasure in laying the results of future experiments before the members of this Society.

Mr. Wall continued: He thought the subject was a most important one, and he strongly recommended Mr. Clark to think over the points thrown out for his consideration.

The Chairman said although Mr. Shadbolt's opinion did not coincide with that of Mr. Clark, still they must be gratified to find that the latter gentleman's paper was of sufficient importance to have been the subject of particular remark in such an important Journal. He quite agreed with the Editor of the Journal and their Secretary that the subject was a most important one; and he trusted that by its pursuit the method of taking coloured photographs would eventually be discovered. It was, however, most necessary that the processes adopted and their results should be carefully recorded. He recollected on one occasion seeing Mr. Shadbolt taking some views, when he observed that the pictures on being taken out of the camera were beautifully coloured; but whilst they were looking at them the colours disappeared. It appeared to him that the question of the production of lasting colour depended more upon the nature of the surface than upon the transmission of light. It had struck him that if it could be preserved from contact with the air by being fixed under water the desired result might be obtained. It was well known that by altering the surface (as by pounding) some substances lost their colour, and that the same effect was produced by viewing them in different lights. Thus the surface of the table-cloth before him appeared green, because it absorbed the red rays, and reflected the blue and the yellow ones. If, instead of the gas which consisted of the three coloured rays, they could view it by a light composed of two rays only, the table-cloth would appear to be of another colour entirely. He should be glad if this subject were investigated by the experimental committee.

Mr. Ackland said: At the last meeting of this Society, during the discussion that followed Mr. Hughes's paper *On the Mechanical Adaptation of Portrait Lenses to View Purposes,* I was asked by a member how photographers could tell when one axis of a lens was central? and in reply, I stated that it was a "trade secret known only to a few."

In The British Journal of Photography for November the 1st, Mr. Shadbolt states, that in making this remark I must surely have been joking; and he then proceeds to divulge this secret, lest the readers of that Journal should have a laugh at his expense for allowing such a statement to remain unnoticed.

In reply to these remarks, I beg distinctly to state, that no photographer can determine whether a portrait lens is properly centered by the method proposed for that purpose by Mr. Shadbolt, even if he possess a good lathe and sufficient mechanical skill to use it properly.

I do not attempt to deny but that it would be possible by this plan to ascertain if a "view" lens was properly central, but I deny that it is at all applicable to the portrait combination.

The remarks that called forth this inquiry at the last meeting were made by myself in reference to portrait lenses, and the gentleman who made the inquiry, no doubt, referred to the portrait combination; and I again repeat that the plan I practise to determine the proper centering of lenses is a secret quite unknown to many lens makers, and even to Mr. Shadbolt himself.

Wherever I meet with a number of lenses by the same maker I carefully apply my test, and it frequently happens that not more than one lens out of six is centered properly; hence I infer that such a maker is ignorant of the plan I use, for did he possess it we may reasonably suppose he would apply it, and thus improve his productions without increasing their cost.

There are two makers whose lenses are properly centered, hence I infer they know this "trade secret."

I make these remarks lest the members of this society should imagine that I had been (as Mr. Shadbolt suggests) joking at their expense, and to disclaim being the inventor of this "secret."

The Chairman said he did not think that Mr. Shadbolt intended to cast the slightest imputation upon their Vice-President. It appeared to him that they were fighting against a shadow. He supposed that there were two ways of doing the same thing:—the one described by Mr. Shadbolt was a rough way of proceeding, useful enough in ordinary cases; and the other known to Mr. Ackland was a method by which mathematical accuracy might be obtained when required. Thus both were right in their way.

Mr. Ackland said Mr. Shadbolt's plan involved a first-rate lathe and brass-work of the best workmanship, and even then he would have the greatest difficulty in fixing the brass truly in the lathe, whereas by his plan any lens could be tested in ten seconds. Mr. Shadbolt's plan would only answer in any case for single lenses. His plan was not an invention of his own, for it had been published years ago; but it had been overlooked, and it was now a secret only known to a few.

Mr. Hughes said he could not help protesting against any one person claiming a superior method of proceeding, when he did not state what that method was. They had Mr. Ackland's word that it was a better method; but they had no means of comparing the results, or testing the working of the methods when one was unknown. They were not, therefore, in a position to give the unknown method the palm for mathematical accuracy. Mr. Shadbolt's plan was so far accurate that, if when the lens was revolving in the lathe, the image of the candle placed before it did not remain still, it was clear that the axis of the lens and of the lathe were not identical. If the lens were central, the image would not move. That was the usual test adopted in the optical trade.

Mr. Ackland asked whether Mr. Hughes could test a portrait lens accurately by that method?

Mr. Hughes said he thought he could.

Mr. Ackland said the inaccuracy of the axis arose from several causes—such as the lens being improperly ground, the cells being improperly cut, and the lens being improperly mounted. He could ascertain whether a four lens combination were accurate directly, and where the defect, if any, lay. He denied that that could be done by Mr. Shadbolt's method.

Mr. Hughes again protested against Mr. Ackland's secret method receiving the palm for accuracy.

The CHAIRMAN said he did not profess to hold the balance between them; but he thought that however true Mr. Shadbolt's method might be when testing one single lens, it could not well be accurate when testing a combination. He did not know that Mr. Ackland's method was more accurate, but he merely took for granted what that gentleman said.

Mr. ACKLAND here offered to show his method to the President, and to let him judge of its superiority. [No member having a portrait lens with him the proposal could not be carried out.]

Mr. HUGHES said that even if there had been a portrait combination present he should not have acquiesced in such a proceeding. This sort of meeting ought to be devoted to the discussion of matters in which all could join. He was sorry that their time should be taken up by invidious remarks, as it placed all of them in a false position.

The CHAIRMAN said he was not at liberty to stop any discussion.

Mr. ACKLAND said he should not have mentioned the matter if Mr. Shadbolt had not commented on his remark in the way he had done. He had only endeavoured to get out of an inconvenient question in the quietest way he could. He had not made it for business purposes, nor for the sake of making a boast of knowing what others did not know. All he could say was that he was possessed of a method Mr. Shadbolt was not acquainted with. He had considered it to be his duty to make the observations he had for the sake of his character.

Mr. WALL, the Secretary, said that at all events possessing and retaining a trade secret was not such a very heinous crime, neither was there anything dishonourable in so doing; but making that out to be a secret which was in point of fact no secret was at least ridiculous, and no person ought to be lightly charged with having done so. As Mr. Ackland had now placed himself in a proper position the matter had better drop.

Mr. LEAKE very much doubted whether combination portrait lenses could be properly tested in a lathe.

Mr. HERVE thought Mr. Shadbolt fancied Mr. Ackland was referring to a single lens. He had seen lenses tested in the lathe when the image "wobbled" or not, as the lens was accurately or inaccurately centred.

As we are at present so severely pressed for want of space, and Mr. Hervé's paper, however excellent, does not involve any actual novelty, we are compelled to omit it.—A vote of thanks was tendered to Mr. Hervé.

The CHAIRMAN said that Mr. Hervé's paper was most valuable, as containing the experience of a practical photographer. It would be of benefit not only to beginners, but to men who had met with difficulties for which they could not account.

Mr. MARTIN, referring to an observation made by Mr. Hervé whilst reading his paper, "that he preferred to filter his bath very slowly," asked his reason for preferring slow filtration, which certainly appeared to him at first to be very objectionable, as proto-oxide of iron would be formed by exposure to the atmosphere. Mr. Hervé also recommended ammonia to be added when the bath was too acid. That would form nitrate of ammonia, in which nitrate of silver was soluble. Ammonia ought not to be employed when a fixed alkali would answer the purpose better. Why did Mr. Hervé add collodion whilst preparing his bath? He presumed it was done to saturate the nitrate of silver with iodide, but he thought it was better to do so by iodide of potassium without ether, which it would acquire soon enough from the plates.

Mr. HERVE said his reason for adding the collodion to the bath was that it made the bath immediately fit for use, which it never was by the addition of iodide of potassium. With regard to the formation of protoxide of iron by exposure in slow filtration, he forgot to observe that he covered the top of the funnel with a piece of glass. The filtration removed any protoxide of iron that might be formed. With respect to the addition of ammonia, he must say he never found a bath require any, but a very slight quantity need be added, and the *liquor ammoniæ* ought to be used. If a carbonate were used it would require refiltration. Thus kaolin could not be removed under twenty or thirty filtrations, and even then it would leave a deposit on the plate. He found that that developer brought out the picture better than any other.

Mr. HOWARD said Mr. Hervé objected to the use of gutta-percha baths. Now he had a gutta-percha bath covered with shellac, which was perfectly hard, insoluble, and non-absorbent. Nothing could be better.

Mr. HERVE observed that the gutta-percha was elastic, whereas the shellac was not, and in consequence when pressure was applied the shellac would crack.

Mr. SIMPSON stated he had used gutta-percha for years successfully.

Mr. S. DAVIS confirmed Mr. Simpson's statement. He had a top once made with vulcanised india-rubber which spoiled the bath, but on altering it to pure india-rubber it answered perfectly.

Mr. HERVE said any body putting vulcanised india-rubber on a bath must be very silly, as the sulphur must of course injure the bath. He had a French-made gutta-percha bath once which turned his bath pink, and that he found arose from some soluble matter in the gutta-percha. He had several gutta-percha baths that he had been compelled to throw aside as perfectly useless. Why not use glass? It was easily carried, equally cheap, and excellent in every respect.

Mr. S. DAVIS said the vulcanised india-rubber bath he once had was warranted not to contain sulphur, but he found that it did.* He now used vulcanised india-rubber covered with a thin coating of gutta-percha.

* Vulcanised india-rubber is sometimes made with sulphuret of antimony, instead of free sulphur. A difference which, to a non-chemical manufacturer, would seem to justify him in asserting that it contained no sulphur.—ED.

Mr. HUGHES said the reason for using vulcanised india-rubber—which was open so obviously to the objection of containing sulphur—was that pure india-rubber was extremely sensitive to the variations of temperature, and that it was too elastic. Vulcanised india-rubber was not open to those objections, but it ought to be coated with a thin sheet of pure india-rubber to prevent its coming into contact with the bath. Gutta-percha might also be used for the coating, but there were some trifling objections to that to which the pure india-rubber was not open.

Mr. S. DAVIS then read a paper *On a Simple and Efficient Preservative Process*. [See page 346.]—Thanks were then voted to Mr. Davis for his paper.

Mr. WALL begged that the paper might be referred at once to the experimental committee, as there was not time then to discuss it; which course was adopted.

Mr. SAMUEL FRY, of Brighton, read a paper *On Instantaneous Photography*. [See page 348.] He exhibited several finely-executed pictures taken on three negatives.—A vote of thanks was given to Mr. Fry for his paper.

The CHAIRMAN said, by the means adopted by Mr. Fry, skies could be introduced into photographic pictures, and portraits could be taken without the sitter being compelled to look at a fixed point for a long time, whereby his face became almost burlesqued. Atmospheric effects could now be produced, and life could be given to the picture. A great number of persons objected to the principle of composing pictures by several negatives; but it appeared to him that when there was only one way to produce a given, and at the same time a true, effect it must be a fair way. If atmospheric effects and foreground could not be taken on one negative, by all means use two or even more. That which came nearest to nature was surely the most justifiable method to pursue.

Mr. Cotton said that instantaneous photography might give a better expression; but it would not give so good a photograph in portraiture.

Mr. HERVE said instantaneous photographs had been taken of different parts of the body at the same time. He did not think, however, that in a glass house in London the light was sufficiently strong for instantaneous photography. He had certainly taken instantaneous photographs in London, but it was with one of Voightlander's quickest lenses. Dust after rain would entirely prevent a picture being taken instantaneously. He thought it lay with the chemist to do a great deal towards rendering photography instantaneous.

Mr. WALL said it showed a great amount of philanthropic feeling on the part of Mr. Fry, who was a gentleman practising his profession, to come forward and give them in a few minutes the experience of years of labour. Such actions made them think better of mankind, and was one of the great benefits derived from societies like these. He was glad to see a practical photographer stepping forward to show the advantage of art culture. Nothing had been so horrible and offensive as the white paper skies—or rather no skies at all. If they would hold a piece of paper over the sky in one of Mr. Fry's pictures they would perceive that more than half the beauty of the picture was gone. He was quite sure that, if the subject were placed in a proper light, pictures might be obtained equally good by instantaneous photography as by the ordinary method.

Mr. HANNAFORD then moved the adjournment of the discussion until the next meeting.—The motion was carried.

Mr. SEBASTIAN DAVIS exhibited a new developing-box, with camera attached, for stereoscopic pictures by the wet process, folding up in a space fourteen by six inches. A hood of lined black calico cloth, under which the head can be put, does away with the necessity of looking at the plate through coloured glass when developing. He also exhibited a new box for carrying plates without injury to the film.

The thanks of the Society having been given to Mr. Davis,

The CHAIRMAN announced that the next meeting of the Society would take place on the 20th of December, when Mr. Wall would read a paper entitled *Photographic Portraiture, with a Glance at Its Comic Aspects*, illustrated by photographs, and a report of the experimental committee.

The meeting terminated with the usual vote of thanks to the chairman

BLACKHEATH PHOTOGRAPHIC SOCIETY.

THE first monthly meeting of the members of this Society was held on Monday evening, the 19th ult., at the Golf Club House, Blackheath,—the President, C. Heisch, Esq., in the chair.

In the absence of the two Secretaries of the Society, the CHAIRMAN read the minutes of the last ordinary meeting, and also of a special general meeting, which were confirmed.

The CHAIRMAN regretted that Mr. Heath, who had promised to read a paper to them that evening, was unable to do so in consequence of his specimens having been mislaid. His paper would most probably be read at their next meeting, and in the meantime he had sent down some very beautiful photographs of views in Devonshire, to one of which their attention would be more particularly directed, later in the evening. In the absence of any other paper he (the Chairman) begged to offer a few remarks upon the subject of *Toning Positives*, a subject of great importance. Latterly a new system of toning positives had come into vogue, called the *Alkaline Gold Toning*. That method possessed such manifest advantages that its disadvantages had been hardly at all considered. The rapidity with which the operation could be performed, and the very

great certainty of securing any tone desired, were two of its known advantages. It also had been said that prints toned by it possessed greater stability than those toned by the old method; but that was a point on which he thought a conclusion had been come to rather too rapidly. If it were *as stable* as the old process it would be universally adopted in preference; but they must hesitate a little before they came to a decision upon mere theoretical grounds when they had such short practical experience upon the subject. So far as his experience went he was not sure that it was so stable as the old process. The theoretical reason given for supposing it more stable than the old process was, that all the decomposition that took place between the chloride of gold and the hyposulphite of soda, mixed in the old toning-bath, was avoided, so that there was no deposition of sulphur. He believed that the old process had been very much maligned, and that it would be very much more stable if people would take the trouble to carry it out properly. Those who put their prints into the toning-bath without washing, or worse still, who added nitrate of silver to the bath for the mere purpose of more rapidly obtaining the desired tone, had, of course, no reason to complain if their prints faded. The proper method, in his opinion, of using the old process was this:—Make a solution of hyposulphite of soda, containing one part of hyposulphite of soda in two parts of water. Dissolve the necessary quantity of chloride of gold, which varies a little according to the tone required, in half as much water as was mixed with the hyposulphite of soda. Add to this a sufficient quantity of carbonate of soda to make it alkaline, and then pour it gradually into the solution of hyposulphite of soda. If that were done carefully very little decomposition would occur. If any sulphur were deposited it should be filtered off before using the bath. Wash the prints well so as not to leave the slightest portion of nitrate of silver on them, and then place them in the bath until the desired tone is obtained; then wash them well in two or three waters, and put them into a clean solution of hyposulphite of soda, consisting of one part of the salt to six parts of water, and allow them to remain in that from a quarter to half an hour, and wash them thoroughly in water. In that way he believed prints might be well toned and rendered perfectly safe. He had prints toned in that way nine years old that had been subjected to a variety of illtreatments,—sometimes being kept in the light hung up in frames and then taken out and put in dark drawers, others had been sent to exhibitions, and several across the sea. He had one that had been taken without any glass to New Orleans in an ordinary travelling box, and which subsequently made a tour through Canada. That was a trial to which few photographs had been put, considering the warm moist atmosphere of New Orleans. [This photograph was produced, and appeared to be in as good a condition as when originally printed.] His reasons for considering that the alkaline gold toning was not more permanent than the old process were these:—In that process the print was put into a mixture of chloride of gold and carbonate of soda. When toned it was taken out and put into a solution of hyposulphite of soda. Carbonate of soda and chloride of gold were thus in both processes put into the hyposulphite of soda, and any decomposition which took place in the old process in the bath, took place in this in the pores of the paper. If it were certain that the liability to fade was owing to the mixture of the hyposulphite of soda and chloride of gold, there was equal danger in both processes. In fact, he had prints toned by the new process only twelve months old which had shown symptoms of fading, although he was not prepared to say that it was owing entirely to the alkaline gold toning. He had hoped to have laid before the Society the result of some experiments he had made upon the subject. Those experiments would not have settled the question entirely, but they would have shown whether or not a print toned in the old way really contained more sulphur than one toned by the new plan. Up to the present time sulphur had been looked upon as the great enemy to the stability of photographs, and therefore the presence of sulphur would be the thing to look to in determining theoretically which was the most likely to suffer. He took a piece of sensitised paper, which he divided by weight into three equal portions, and exposed half of each to the light. He then toned the first piece by the alkaline gold process, and the second by the old process, leaving the third without any fixing at all, merely washing it well in water. He then boiled all three in nitric acid, which converted any sulphur they might contain into sulphuric acid, the quantity of which was determined in the ordinary way by sulphate of baryta. He took the untoned piece as a starting point; but he found that the whole quantity of sulphate of baryta was so small that no deductions could be drawn from any apparent differences, which came fairly within the limit of the errors of experiment. He however should repeat the experiment on a larger scale, when he would communicate the results he then obtained. He wished particularly to point out to the working members of the Society that the stability of the alkaline process required most jealous watching, and that he at present did not see any reason for considering it more stable than the other. One very great advantage in the alkaline process was that it was not necessary to *over print* the positives; whereas, under the old system, they required over printing, which was a very tiresome operation. However, he was not quite sure but that very much over printing thoroughly baked the image into the paper, and gave the stability so much desired. He saw that Mr. Thomas, in his recent paper, mentioned the fact that photographs printed in the sunlight were much more stable than those printed by diffused daylight. In this he quite agreed; but there was one point that Mr. Thomas had not noticed, namely, that the sunlight penetrated the dark parts of a negative, and brought them out much more in proportion to the lighter parts, than diffused daylight. [He exhibited a stereoscopic view of a coast scene in which, when printed in the sun, the distant cliffs were well shown without the foreground being over printed, while with the same negative printed in diffused daylight the foreground was quite burned up, and not a trace of the distant cliffs could be seen.]

Mr. Glaisher remarked that his experience quite coincided with this.

Mr. Skaife said he found that he could print from a very weak negative, almost a positive, in the sunlight, which he could not print at all in diffused daylight.

The Chairman then exhibited some stereoscopic views he had taken at Lynton and other parts of Devonshire on plates prepared with raspberry syrup, as recommended by Mr. Sisson. The collodion used was made from *paper* no less than six years ago, which he considered was a complete answer to those who said that collodion so made carried in itself the seeds of its own decay. He also exhibited the specimens by Mr. Heath, above referred to, taken in the Duke of Bedford's grounds at Tavistock. The one especially referred to was twelve by ten inches, and was taken with *the smallest-sized orthographic lens*, by Ross, with a No. 2 stop. The lens was only warranted to work upon a plate 8½ by 6½ inches, its focal length being 12 inches; yet it would be observed that even the edges of the picture were perfect. The others were taken by one of Grubb's lenses.

A discussion ensued relative to the printing of the photographs to be distributed among the members.

Mr. Skaife exhibited some chromo-crystal portraits produced by his pistolgraph, among which was the one of Sir David Brewster.

After some further conversation, the proceedings terminated with the usual vote of thanks to the Chairman.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

This Society resumed its meetings for the season on the evening of Tuesday, the 13th ult., in George Street Hall, Edinburgh. Sheriff Moir occupied the chair.

On the table were some specimens, contributed by M. Joubert, illustrative of his enamelled process on glass, and also of his carbon process on paper. They were inspected with much interest. A letter from M. Joubert, accompanying them, was read, but there was nothing of general interest in it.

Mr. Colin Sinclair exhibited a number of very beautiful prints by Continental and other artists.

The minutes of the last meeting having been read,

The Chairman, after regretting that Sir David Brewster, the President of the Society, was unavoidably absent on that occasion, stated that this had been an extremely bad year for photographic pursuits, and he was afraid it would tell very much on the next exhibition; still, from the fact that in certain quarters very considerable improvements had been made, they might perhaps venture to hope it would not be quite so bad as some might anticipate. It had been suggested to the council that the particular time of the year at which the exhibition of the Society was usually open was not the best; and accordingly this year the time of opening the exhibition would be postponed from Christmas till February. Some might think this alteration would bring it into competition with the other exhibitions of paintings then open; but this, instead of being a drawback, would, in his opinion, be a positive advantage, as those who visited the one would most likely not be satisfied without visiting the other. He thought it was a most judicious alteration, especially when the present state of the weather was considered. It was a matter of regret that on the present occasion there was no paper to be read; and he would urge on those members who were able to write papers to do so, in order that the like might not occur again. It was not necessary that such papers consist of new processes or discoveries, but the members might detail their experience in working. For instance, in preserving plates with wort, as recently brought before their notice by Mr. Macnair, many who had tried it got nothing but failures, while Mr. Macnair himself, and others, had been quite successful. This was one of many similar cases on which varied experiences might advantageously be brought to bear. For the present there was nothing but an exhibition of some pieces of apparatus, which some gentlemen had kindly agreed to show.

Mr. L'Amy exhibited Skaife's patent shutter for instantaneous exposures. This was a slide made to fit in the camera, just behind the lens. It contained a pair of folding doors, like the shutters of Daguerre's original camera, with an india-rubber spring so arranged that, when opened, it closed with great rapidity. The cost of it was according to size—that exhibited (a small one) cost about a guinea. Mr. L'Amy also exhibited a species of turning lathe he had invented for cleaning glass plates. It is on exactly the same principle as the albumen disintegrator of Mr. Noton, (a drawing of which appeared in the last number of The British Journal of Photography), a series of buffs being fixed on the small wheel. Mr. L'Amy gave a practical illustration of its use by cleaning a plate with it, which when done was handed round the room, and pronounced to be very well done. The time occupied in cleaning the plate was not very much more than would have been occupied had it been done by the hand. It requires two persons to work it, one to hold the plate and another to drive the wheel. The cost was said to be about £3.

A camera, manufactured by Mr. Bryson, of brass, with a slide made of a species of india-rubber, was exhibited. Neither heat or acids affected this slide.

Mr. MOFFAT showed Woodward's solar camera, with some specimens.

The CHAIRMAN exhibited Melhuish's metal stereo-camera and lenses.

Mr. TAYLOR said that at the last meeting of the Society the pressure of business had prevented them remembering to do a small act of justice to Mr. Kinnear on his retirement from the secretaryship of the Society. It was not enough that such services as Mr. Kinnear's should be passed over with a mere formal vote of thanks; he moved that the silver medal of the Society be presented to Mr. Kinnear, as a small recognition of his services. This was unanimously approved of.—The meeting then separated.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting was held on Wednesday, the 14th ult., at the Chorlton Town Hall,—Mr. W. Griffiths, one of the Vice-Presidents, in the chair.

In opening the proceedings the CHAIRMAN regretted the absence of the Honorary Secretary, who, he was sorry to announce, was through illness unable to be present. Mr. Sheard, who kindly undertook to supply his place for the evening, then read the minutes of the last meeting, which were confirmed.

Mr. WARDLEY stated that he had no doubt most of them had seen an article that appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY, of November 1st, by T. F. Hardwich, in which an address delivered by their Chairman at a former meeting had been, according to his opinion, unfairly commented upon. He could not agree with some of the opinions expressed, particularly those in reference to the progress that had already been made in photographic chemistry. For his own part he doubted whether they knew any more of the nature of the various chemical changes which took place in photography than they did at the time when the collodion process was discovered. He had thought this a matter of sufficient importance to warrant him in bringing it before the members, as some might wish to give their opinions upon it; and in order that they might be in a position to judge of the facts, he would call on Mr. Sheard to read the article from the Journal of the 1st, and afterwards the reply of the Chairman, which would be found in the one for the 15th, which had just come to hand. The two having been read,

Mr. SHEARD said he could not understand the object Mr. Hardwich had in view in his "Comments;" for he did not deny any of the statements in that part of the address to which he more particularly objected as being contrary to fact, but merely took exception to the policy of ever reminding members of a photographic society of the unsatisfactory chemical condition of the art. It appeared to him that so unimportant a matter as this did not deserve the prominence Mr. Hardwich had thought proper to give it.

Mr. ROGERSON thought, and several other members concurred, that if no allusion to collodion had been made in the address, the whole matter would have been passed over in silence.

After a further expression of opinion on the part of other members, approving of the reply which had just been read, the subject dropped.

Mr. GRIFFITHS then read a paper—

On the Preparation of Iodo-Nitrate of Silver: its Chemical and Photographic Properties.

HE began by describing its preparation from the two salts, as also its formation in the working of the collodion and other processes, and then explained its chemical nature and reactions. He said that the photographic properties of this compound were deserving of far more consideration than it appeared to him they had yet received. All the processes that we were accustomed to work, and in which iodide of silver formed the sensitive medium, with the exception of the daguerreotype, were dependent mainly upon the presence, in minute quantity, of this salt for their sensibility under actinic influence, and not, as was generally supposed, to the presence of free nitrate of silver. In support of these views he described in detail several experiments he had performed: one in which he had prepared several collodion plates in the usual manner, but on taking them from the silver bath they were deprived of every trace of free nitrate and dried. In this condition the film of collodion was ascertained by an appropriate test to contain both iodide and iodo-nitrate of silver; upon exposure these plates had invariably been found equal, if not superior, in sensitiveness to others prepared from the same collodion, exposed wet, and with excess of free nitrate. He believed that a more extended investigation into the properties of this salt would have the effect of satisfactorily clearing up many of the difficulties connected with the working of the dry processes, as well as explaining some of the phenomena which were constantly being brought under our notice. He then called the attention of the members to the retarding effect as respects sensitiveness produced by adding iodine to collodion. He did not think the generally received opinion that this was owing entirely to the liberation of free nitric acid in the bath was quite correct, for the quantity set free by using a collodion containing even as much as one grain to the ounce would be so exceedingly small as to make it very doubtful whether this ought to be accepted as a true explanation. From the result of some experiments he had made he believed it to be owing more to the formation of iodic acid, which might occur in the following manner:—For every six atoms of iodine in collodion five atoms of iodide of silver, one atom of iodic acid, and five atoms of nitric acid resulted upon dipping the plate in the bath of nitrate of silver. The nitric acid, from its powerful affinity for water, was quickly disseminated through the bath, and in consequence its influence was diminished; but the iodic acid remained partially imprisoned in the film with the iodide of silver. They were all aware of the retarding effect produced by free nitric acid in the bath, but according to his experience this was slight as compared with that exercised by iodic acid under the same circumstances. On some future occasion he hoped to have an opportunity of explaining to them what he believed to be the *rationale* of the effect produced by free acids in the bath in diminishing sensitiveness.

A long and animated discussion then followed.

A MEMBER exhibited a negative portrait on glass, which had been developed with sulphate of iron after an exposure slightly greater than would have been required for a positive: after it had been fixed and well washed it was at once covered with a saturated solution of bichloride of mercury in water, which was allowed to remain on till the image became whitened. It was then again well washed, and lime water diluted, one-half was poured over it, when, after a short time, a dense and very satisfactory negative was the result. It was handed round for inspection, and was greatly admired for the softness and delicacy of its half-tones, which were perfectly preserved.

Mr. SHEARD wished, before the members separated, to correct one or two errors in the report of the last meeting as it appeared in the Journal. The first error he wished to have corrected was one in which he was reported as having said that the plates prepared by hot water had not in his hands turned out satisfactory, whereas what he stated and gave the meeting to understand was the direct contrary. Another error was that in reference to the cause of his failures, which was not fog, but a peculiar water-marking near the borders of some of his plates. [A letter from Mr. Sheard on this subject will be found among our "Correspondence."]

After the usual vote of thanks, the meeting was adjourned.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER VIII. *(Continued.)*

MATERIALS, &c.

TO resume our studies, let us still give that attention to the subject of vehicles or mediums which its importance demands. In painting in oil we meet certain difficulties, the proper combating of which (if you be an honest man) should always be made a matter of thought in your practice. Vehicles containing oil have more or less a tendency to discolour in time, and for this reason varnish and turpentine are added to as great an extent as is consistent with their proper manipulatory qualities. Being of great importance to the purity and brilliancy of your tints, the more colourless your vehicle the better; but I should prefer a vehicle which, although slightly coloured at first, underwent but little after change, to one that, colourless to begin with, darkened upon exposure to light and air; because in the one case I might, during work, aim at counteracting its tendencies, and in the other I could not. I have before referred to the yellowish-brown, leathery appearance assumed by photographs coloured with oil glazings only, in consequence of the quantity of vehicle being in undue proportion to the amount of pigment; but without due and proper care the same defect will mar the beauty of even a solidly-painted picture. To ascertain the character of your vehicle in this respect, try it with a little white. When in old pictures you see the delicate purity of a fair face changed to a tawney yellow, some brilliant azure sky turned to dingy green, or once white drapery of the colour of wash leather, you may set it down to the injudicious use of certain vehicles, and make up your mind to a careful and studious choice of such for your own work. That these defects, common as they may seem, are not absolutely inseparable from the use of oil colours, is proved by the fact that the pictures of Titian, and so many of the Venetian masters, still retain nearly all their original loveliness and purity of colour. Very great attention has been recently directed into this channel, and we now have a great variety of excellent vehicles or mediums prepared and sold for use.

You have all heard how our photographic brethren talk about collodions:—one denouncing A's, but praising B's; another extolling A's, and sneering down B's; while a third laughs both to scorn, and cries "whose equals C's?" Now much the same thing is done by artists in recommending vehicles—one praising this and another that. A vehicle now much used by artists of position and talent is copal varnish thinned with turpentine. Now I cannot use this;

but that is no reason why you should not try it. Miller's * glass medium is another vehicle which many of my brother painters denounce, but which I use and like vastly: its chief defects are, that it hardens very slowly and dries rather too rapidly during work. You cannot knock the colour about with impunity with this vehicle; and it is frequently a long time before you can put a second painting over your first. But it is quite colourless; does not appear to be greatly altered by time; leaves your whites *white* and not buff; accordingly does not destroy the delicacy of your tenderer tints; and when dry is very hard.

There is a "marble medium" for use with oil colours, sold by Robertson, of Long Acre, invented by Mr. Parris (an eminent photographic colourist) for repairing Sir James Thornhill's pictures, in St. Paul's. It dries very hard, and without gloss. I have heard good photographic colourists recommend this medium very strongly. Wax, it should be remembered, becomes discoloured almost as readily as oil, and of this the marble medium certainly contains a large proportion.

By-the-bye, I may as well seize this opportunity of reminding or informing you that oil colours are sure to become discoloured if deprived of light. For this reason it is very bad policy to shut them up in the ordinary miniature cases.

Having laid before you the disadvantages of a vehicle containing too much oil, I must now prevent you from running to the other extreme. Varnish, when used in too large a quantity, is a fruitful source of cracking, because of the oil of the last-applied colour being absorbed into that of the previous painting—the top surface drying quicker than the lower becomes rent.

It may be more fair—for, after all, not my words but your own good sense will be your better guide—to add that Haydon, and other eminent practical writers on art, advocate the use of pure oils, "Honest Linseed" more particularly.

Magilps are mixtures in various proportions of varnish and oil, varying in their characteristics according to the nature and quality of the materials. Mastic varnish and drying or prepared linseed oil forms a magilp which is sometimes called English varnish, which the amateur will find most manageable; but some painters prefer that prepared with copal varnish. Other oils are also used for the purpose.

Another vehicle, sometimes much valued by artists, is prepared with nut oil, litharge, and pure white wax. Take two parts of the first, one of the second, and a small portion of the latter, and with your slab and muller grind them well up together, diluting afterwards with a little mastic varnish.

A vehicle which unites some of the qualities of oil and water in a very useful way is made by dissolving one part borax in twelve of boiling water, to which is added an equal portion of white lac varnish. This mixes readily with your oil colours and dries very quickly, removing also some of the objections noticed in the use of vehicles more purely oil. (A little time since I heard of the above receipt being sold for rather large sums as "a great secret.")

There are a great variety of mediums and vehicles, some of which are admirable in use and result, but I might confuse you, perhaps, did I dwell upon them, although I think it very necessary that you should try several vehicles, inasmuch as with some you are sure to work better than with others. For instance, one painter, experienced though he might be, would work with slow and uncertain touches; for a vehicle which dried too rapidly would be quite unsuitable, inasmuch as he would be unable to alter or retouch. Again, another who worked as slow, but was more certain, would like his colours to dry quickly, in order that they might not be disturbed or altered by his after touches; and so on *ad libitum*. Find therefore that medium which, otherwise unobjectionable, best suits your peculiar practice or facility of hand.

* Of Long Acre; I forget the number.

Foreign Correspondence.

Paris, November 27, 1860.

The present is decidedly a moment of repose in the product of new processes. Innovations are becoming rare; and I see from the reports of your own societies that the same thing is noticeable in England. All the efforts and labours of photographers seem tending to new applications, and especially to the improvement of results already obtained. However, I have to mention a communication made last Friday, the 23rd, to the French Photographic Society, and which excited a lively interest: it was on M. Fargier's printing process. At the preceding meeting some specimens, sent by the inventor, had been much remarked and admired, as superior to those printed by the usual means from the same *clichés*. It was only regretted that the mode of operating had not also been given. This time, M. Fargier, having secured his interests by a patent, described his method. It is far from being complicated, as you will see; and the beauty, I might almost say the perfection, of the results obtained is solely due to the following simple observation, which the inventor has known how to turn to account:—When a transluced body, sensible to the light, is submitted to its action, that action commences at the surface, and extends more or less into the interior, according to its greater or lesser intensity; that is to say, it penetrates very far into the portions corresponding to the whites, and but a little way into the half-tints, and so on. M. Fargier covers a glass with gelatine containing charcoal powder in suspension, and sensitised with bichromate of potash. Then, having applied the negative to be reproduced, he exposes the glass to the light. So far, there is nothing very new. But, after the exposure, he spreads collodion over the surface, and plunges the whole into warm water. The double film of gelatine and collodion comes off from the glass, and all those parts of the gelatine in which the bichromate has not undergone the action of the light, dissolve; the result is that the whole image remains on the collodion with which it has been in contact. The picture, with the collodion uppermost, is fixed on a sheet of paper. In this manner the most delicate parts of the picture are preserved in all their purity, and the modelling is exquisitely fine.

A communication of another kind, though equally interesting, consisted of several gigantic portraits, presented by M. Disderi, and which he had taken with the help of Wothly's process and amplifying apparatus. The most sceptical were obliged to acknowledge the merits of these truly artistic works.

It seemed as if the portraitists had conspired to engross the Society's attention on this occasion. M. Camille Silvy had sent from London a series of visiting cards of remarkably good execution. His special endeavour is to operate very rapidly. Several portraits of children, and a picture representing a horse in movement, told of his perfect success.

Mr. Bingham placed before the meeting several positive pictures printed with electric light in less time than that required by solar light. Mr. Bingham employs Professor Way's lamp, in which, as you are doubtless aware, a train of mercury is substituted for the two charcoal points. The light emitted by this lamp is uninterrupted, and its composition even renders it much more photogenic.

Mr. Harrison presented some small pictures obtained by the steam-printing process, spoken of sometime ago by the American papers. He affirmed that by this process 4000 copies could be printed off in an hour. It appears that this expeditious system has already been put to a somewhat singular use by your Transatlantic cousins. At a recent election, each voter received the portraits of the candidates by way of voting tickets. The idea deserves to be known. As to the means employed for the printing, Mr. Harrison promised a description for the next meeting.

Dr. Sabatier, desirous of proving the applicability of his process, which I transmitted to you in a former letter, to portraits and views, sent several specimens, whose merits were duly appreciated. They are very good pictures, of satisfactory dimensions (full-sized plate), and offering very delicate modelling, combined with great vigour of tone. They do credit to the laborious amateur's method.

Lastly, we saw a very remarkable picture, photographed upon stone from an engraving, and executed by M. Asser, of Amsterdam, by means of the process that he communicated to the French Society in 1859, and which, as he tells us, he has left unmodified.

At this meeting, Count Sevastianoff, a Russian amateur, who has made a long stay at Mount Athos, announced that he had brought back with him 3,500 *clichés*. In this immense collection are especially included a large number of manuscripts and paintings. This will doubtless prove to be a very interesting work, in which the learned will probably discover many a precious document.

ERNEST LACAN.

Correspondence.

PERMANENCE OF POSITIVE PROOFS.

To the Editor.

Sir,—It may seem somewhat out of place publicly to attack a paper read before a photographic society for that particular society's benefit; but when such a paper is printed in the columns of a leading photographic journal it becomes, in a certain sense, public property, and the public has a right to form and express its opinion upon it. On this ground I beg a small space of your columns to notice the paper *On Failures in Printing*, &c., by Mr. Ewing, in your number of the 15th November.

The first impression on one's mind after reading Mr. Ewing's paper is, that he is at least three years behindhand on the subject of which he treats. He animadverts on the *permanence and printing* of photographs precisely as photographers would have done, and actually did, three or four years ago, as though since that period no progress had actually been made in the one or the other.

After admiring Mr. Ewing's poetical introduction of his "failures," we pause at the following paragraphs:—

"Now I will tell you of a great difficulty that stands in our way, and that is a want of permanency in our productions: *our toning and printing have not as yet given us anything that we can with any assurance term permanent.* . . . Certainly this fact demands great attention, as we are very far from having overcome this serious difficulty. . . . With the old hypo. bath there was little or no trouble compared with either of the foregoing (the alkaline and *sel d'or*), and yet I have seen prints quite as clean and beautiful produced with it as with any of the former. . . . But when we place it before the theory of our President it will bear away the laurels in point of permanence. . . . Allowing that the print is beautiful from the beginning of the process until the end, how perplexing is the fact that this same disease (that annoying jaundice colour) after a time returns, and that in a space of five or six years we find our darling subjects spoiled by an incurable attack of yellow fever!"

I must refer those of your readers who wish to know in what connexion these extracts occur to the paper itself. What they may think about this doctrine I cannot tell: to me it appears very much like an attempt to drag us a few steps backwards instead of one in advance. Is it really true, Mr. Editor, that we have "attained to nothing like permanency in our productions?" Have the researches of Mr. Hardwich, Maxwell Lyte, MM. Davanne and Girard, and others, really thrown no new light on the subject? Is the alkaline toning bath inferior to the old gold and hypo. in its capability of yielding permanent proofs? And are all our "darling subjects" really doomed in five or six years to an "incurable attack of yellow fever?" O ye vain, credulous photographers! take a last long look at your "darling" creations before the fatal malady seizes them, and they fade from your fond vision for ever! But cannot we retain them a little longer?—Is there *no* hope? Certainly not from Mr. Ewing; so we must look to other quarters, and, happily, we are at no loss, for I imagine that you, with the majority of enlightened photographers, think very differently on the subject, and have come to the conclusion, if they have read his paper, that he has been guilty of a palpable inattention to facts, to say nothing of theory, when he penned the statements I have quoted. I am not going beyond facts when I state that there are plenty of photographers who could produce specimens in *abundance* by the alkaline bath, which, after an exposure of say three years, do not exhibit the smallest signs of the "yellow fever" attack; but I imagine it *would* puzzle them to produce, in many cases, even a single specimen where these signs *were* apparent; whereas, on the other hand, it would be equally puzzling to produce one by the old bath that did *not* exhibit these signs. I do not say such latter are not in existence, but I do say they are extremely rare, forming the exception, and that a very scarce one, instead of the rule.

Recent investigation, conducted, I believe, in the most scientific and systematic manner, has condemned the old method as entirely *wrong in principle;* and the sad experience of all justifies the verdict, pronouncing it the vile and sure destroyer of all our workmanship. In this dilemma the alkaline bath comes to our aid, and I am not alone when I state my conviction, founded on experience, that prints toned by carbonate or phosphate of soda and gold, fixed in *new hypo.* and *properly* washed, will be found as lasting as the most permanent engraving. After a most critical experiment of prints toned now nearly three years ago, I have failed to detect by comparison the slightest alteration or change; and if they have stood *perfectly* unchanged for three years, is it not a strong presumptive assurance that they will remain so three more? And if they will stand the test of *six* years' exposure without evidence of fading, what shall prevent them standing *sixty?*

We are ill prepared, then, to listen passively to Mr. Ewing, as he steps coolly forward and says that all our proofs are doomed to fade; and, as the best means of preventing it, indirectly recommends his fellow-workers (for so I interpret his meaning) to continue the use of the old gold and hypo. bath.

When a gentleman undertakes to enlighten others on any subject, he ought certainly to endeavour to make himself as well acquainted with it as possible, lest he render himself liable, as in the present instance, to be charged with a mis-statement of facts, and be found advocating a system which the common voice has pronounced unsafe and experience worthless. Mr. Ewing deplores the loss photography sustains by the want of confidence on the part of the public in the permanence of its productions; but his paper is well calculated to foster this feeling, and if all photographers wrote in his strain, and acted on his principle, it would certainly be a long time before such distrust was removed.

I am glad that you, as the conductor of an influential Journal, have condemned the old method as exploded, and given your testimony in favour of its young and infinitely more worthy rival; and I trust the day is not far distant when toning photographs by gold and hypo. in combination shall be known only as a monster delusion of the past.

Apologising for the unexpected length of this letter, I am, yours, &c.,
P. P.

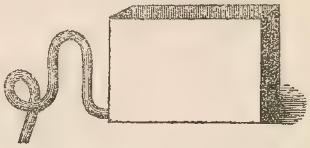
[We believe it to be a recognised custom that all published matter should be liable to fair criticism: the end and object of publication is for the furtherance of our art, and therefore we think our correspondent is quite in order in expressing his views relative to the paper to which allusion is made; and free discussion upon all matters relating thereto is in our opinion one of the best means of attaining that end.

The author of the paper to which exception is taken did well in propounding his views; because, if they be erroneous he benefits himself directly by calling forth arguments against them by those better informed, and if sound he benefits others by his experience: in either case the public receives advantage from one side or other. Truth never loses by discussion; and to the freedom of it we are indebted for the sound principles advocated by our correspondent, who judges correctly in attributing to us coincidence with his opinion that toning by old hyposulphite of soda is wrong in principle, and nearly obsolete in practice; that toning by means of *sel d'or* is only not quite so bad; and that the use of the alkaline gold bath is based upon a sure and scientific foundation, not stumbled upon by accident, but worked out with a definite purpose, from established data to start with.—Ed.]

AUTOMATIC WASHING-TROUGH.—DRY PLATES.

To the Editor.

Sir,—A siphon for a washing-trough, although of larger capacity than the feed-pipe, can easily be made self-acting by merely turning a loop on the long leg, as in this rough sketch:—



The water retained in the loop after each discharge serves the same purpose as the valve which you propose, and has the advantage of simplicity. The above may be of service to your correspondent in the Journal of the 1st November, Mr. W. Church. A few trials may be necessary to determine the proper size of the loop. Although I have had little or no experience in any of the dry processes, I prepared two 9 × 7 plates, according to the formula of Messrs. Petschler and Mann, a few days after it appeared in the Journal. The plates having been coated with chlorided albumen and dried, one of them was exposed to ordinary daylight, the other kept in the dark. Both being then well washed and dried, were exposed in the camera at the same object. On developing, the plate that had been kept in the dark turned out a very good negative indeed; the other, to my surprise, came out a positive by transmitted light, but very much fogged. I have had no time to repeat the experiment.—I am, yours, &c., WM. RODGERS.

November 5th, 1860.

A BREEZE FROM SOUTH KENSINGTON.

To the Editor.

Sir,—Whatever is the matter that you should begin to "kick up such a row" because our Government intends to start photographing? What strange thing has befallen you? If I am wide awake and understand what I read, and believe what I have read for years about cameras, optics, chemicals, and photographers, I might say with you and some of your correspondents "more the merrier;" but "it is a long lane that has no end," and I think the end of profitable photographing is just a-head.

You have well said that photographers are a patient class. I think so too, and often wonder that no pen has been taken up to write in their defence. Many of them are artists, driven from their favourite pursuit of painting, and might have obtained a respectable living in this new line; but down rushes a torrent of amateurs, cobblers, tinkers, tailors, lawyers, clerks, doctors, and parsons, egged on by the everlasting baits held out by

journalists, camera and chemical sellers, giving instructions for buying their stuff. Why not offer to give instructions for buying medicine to heal their bodies? Why not give instructions in electro-plating, electrotyping, lithographing, the use of microscopes, telescopes, and all other scopes (echo answers "why not?"), as well as cram the world full of photographers? "But," says Mr. Griffiths, in Chorlton Town Hall, "if we would know the estimate in which photography is held, we have only to walk through the streets of our towns, and note down the number of galleries we everywhere see." Then, if this prove the more the better, why not let governments, nations, and kingdoms be jolly photographers all, and take portraits at twopence a head, as they do in the most fashionable watering places in the East Riding? This we may thank the swarm of amateurs for, who rob the professional man of his daily bread. I can speak feelingly: my profits have not cleared my chemicals for months.

A Belgravian puppy was lamenting in an aristocratic photographic journal some time since that, as he had no more friends to take, he would like to begin to take street views, but was afraid people would stare at him. There were no pistolgraphs at that time; but I could have put him up to a dodge, by dressing him up as a "flunkey," and putting a lens at the side of his hat, tied with a girder: it would pass for a cockade. But no; I had rather he would think how many poor fellows he had robbed of a loaf of bread, by taking his rich friends who could and would have paid some one, had it not been for him, and, as there are some thousands of such rascals, it will tell in time. But why, as I said before, do you find fault with the Government? Let its officials photograph on, and when all the world can photograph all the rest of the world, then we must stop and clap the cap on. As this is the sort of thing you and your brethren have been bringing upon yourselves for years, bear it manfully. I fancy there must be some sore place somewhere. I always find when things come *home*, people *feel* it the best, or rather the most.

I fear that a little knot of you first-class professors has at last got touched in the quick. If so, have a little feeling for us poor from-hand-to-mouth brethren.—I am, yours, &c. DIPPER.

[We are most willing to allow all classes of our readers a fair hearing, hence the insertion of the preceding; but we cannot abstain from replying to some of the remarks made.

If any of the *first-class professors* have been "touched in the quick," they must be those personally unknown to us; and at any rate our correspondent ought to know, if he has been a reader of the Journal for any length of time, that we endeavour to uphold truth and justice, without respect of persons.

"Dipper's" complaint, that the journals have produced such a crowd of skilfull amateurs that professionals cannot get a living by following the art, is at any rate complimentary, though unjust; for he omits to mention also that nearly all professional photographers were originally amateurs. Moreover, were it not for the journals, what would photography have now been? It never could have acquired its present development without the facility of that free intercommunication between its followers afforded by the journals. That many miniature painters have suffered from the advance of our art, is probably true: there never was any great change effected without some individual injury. But we have reason to believe that many more are now earning a comfortable livelihood by making photography an ally instead of an opponent.

The parallel drawn by our correspondent between the amateur and the government department is inapt, because the former buys his own materials and apparatus, and gives away his productions—a proceeding to which he has a perfect right: if he sells them he becomes a professional, and either makes a fair profit or ceases to sell—in either case there is no unfair competition. This is not so with the government department. The professional photographer himself assists in finding funds to enable the government department to undersell him. If he do so voluntarily, we have not the slightest objection; but if not, then we protest in his behalf, for, personally, the matter does not affect us in the smallest possible degree.

We fancy that the "Belgravian puppy," so graphically described by "Dipper," is more of a friend than a foe to him and his brethren; for "rich friends" who have been once "taken" somehow or other generally get a hankering after the operation, and spend twice as much upon being "done" over and over again as those who have never had a gratuitous taste. Either the friend's handiwork is so good that the sitters are delighted, and take all the rest of the family to a "professor," or it is so bad, that they go to the said "professor" if only to show the amateur friend that they (the sitters) are not quite such "Guys" as the photographic friend would lead them to believe.

We come in contact with photographers—professional and amateur—from all parts of the kingdom, and, whenever the question has been discussed at all, we invariably find that the former succeed best, in a commercial point of view, where the latter most abound.—Ed.]

EXPLANATION.

To the Editor.

Sir,—On looking over the last number of The British Journal of Photography I find my name brought into print, and felt somewhat annoyed, not on account of myself, but for the different authors of the "dry processes," who, no doubt, will think, on reading the article in question, that I am a sad bungler, and, before I had attempted to give any opinion, ought to have been able to work some of the said dry methods. The error in question commences with the "hot water," and, for your guidance, I give you almost word for word what I really did say:—

"He had tried a few plates by this process, and found them satisfy—so much so that he thought he could obtain equal results with this as with any other process, and quite as rapid. The only fault he found was a kind of watery mark along the edge; in fact, he might say that he was liable to this kind of marking *more or less* in all the dry processes he had tried. He had brought a negative with him, prepared by the hot water, showing these marks, and wished to ask if there were anyone present at the meeting who could throw any light upon the subject."

You will perceive that the foregoing is quite a different edition to yours. I have made inquiry as to who was the author, but have not got any definite answer. I should not have troubled you, but our next meeting does not take place in time to prepare a report for your next impression; however, I shall bring the matter forward.—I am, yours, &c.,

Manchester, Nov. 12, 1860. THOS. T. SHEARD.

[We are not responsible for the error complained of, having only published the official report.—Ed.]

PREVENTION OF BATH-TOPS ADHERING.

To the Editor.

Sir,—At a recent North London meeting, Mr. Hill and others complained of the tops of their gutta-percha baths sticking. Will you allow me to suggest the use of a thin strip of parchment paper (De la Rue's make), obtainable at Goods', 60, Moorgate Street? The solution has no effect whatever on it, and, of course, it cannot stick. Mr. Simpson's plan is a very good one: to face the rubber on the top with a thin strip of the purest gutta-perha. I have used a travelling glass bath, holding 180 ounces of solution, all the summer!! (such as it has been), with a top of the same sort, with the most perfect success, and without the slightest leakage.

I am delighted to see what Mr. Hughes and others say about the system of rolling albumenised paper, and trust it may be the means of inducing the albumenisers to give up so pernicious a system.

I am, yours, &c. R. GORDON.

SELF-ACTING WASHING APPARATUS.

To the Editor.

Sir,—A gentleman with whom I am well acquainted has his house furnished with a number of ingenious contrivances for the promotion of health, comfort, and convenience. One of these gets over the difficulty experienced by some of your correspondents in constructing a washing vessel that shall be slowly filled and rapidly emptied without personal attention.

About forty feet above the ground is fixed a cistern holding 250 gallons of water, which is discharged once or twice a day through a four-inch pipe into the drains of the house, the amount and force of the current driving every impurity into the sewer.

The pump which supplies the water is worked by a steam engine that is kept going for business purposes; and when the cistern is full, a waste-pipe conveys the surplus into a vessel suspended like a scale-pan from one end of a lever, to the other end of which the valve that covers the orifice of the exit-pipe in the bottom of the cistern is attached by a wire. By a proper adjustment of the size of the suspended vessel, and the axis of the lever to the weight of the valve and the pressure it sustains, the latter is raised and the cistern emptied. In the suspended vessel is a *small* hole, which allows the water *slowly* to run out, when the weight of the valve again preponderates, and it falls on to its feet.

As my experience in washing prints is very limited, I am unable to give an opinion on the respective merits of a change of water in the same vessel, and the lifting of each print singly by hand into another vessel; but, if automatic washing is found to answer, I think an apparatus might be constructed upon the above principle, which would change the water with certainty and regularity. The valve might be made like the clack of a common pump; and, if the vessel were shallow, it would require but little force to lift it.—I am, yours, &c., J.

THE GRAND-PARENT SOCIETY.

To the Editor.

Sir,—Now, I hope I don't intrude, but I thought I'd just drop in to say I've patented it. Of course I mean my celebrated apparatus for keyhole photography.* The idea developed with the first picture I took beautifully; but, however, that's not what I have to say. No! My intention now is to inquire why, when you regularly report the meetings of the Parent Society, I never, by any chance, find in your pages any notice of a society, of the existence of which I had not till quite recently any idea—I mean the Grand-parent Society?

On the evening of November the 6th I was in the Strand, on my way to the first ordinary meeting of the Photographic Society's new session

* See No. 110 of The British Journal of Photography.

(I mean the Parent Society), in Coventry Street, when, behold! I saw a group of photographers (marked men, for their fingers were stained) turn out of the street thro' an archway of stone, and vanish thro' a large door to the left. Ha! said I, what does this mean? These men should be going to Coventry Street, and they are going—where? Egad, thought I, I'll find out; so I followed them.

Now, when I reached the door to the left, I saw a stone hall, and a staircase, but those I sought were invisible. Where could they have gone to? I saw another little man, and I said, "Can you tell me if a Photographic Society, named after any of the points of the compass, holds a meeting here to-night, sir?" For I knew of the South and the North, and thought there might be some unreported East or West Societies, don't you see? And the little man, with great dignity, paused in ascending the stairs, and looking down on me said, "*No*, sir, no such *little* societies meet *here*;—this is the *great*, the Grand-*parent* Society. "Can I attend the meeting?" said I, informing him at the same time that I was a member of the Parent Society. Whereupon, in a most mysterious manner, he ejaculated "Walker!" winked at me, and went upstairs. I stared after him in confusion, but imagining that "Walker" might be his method of expressing "walk up," I followed him.

I'm rather near-sighted, you must know; so I soon lost sight of this eccentric little man, but found my way into a room in which there was, as I was informed, a photographic meeting.

A paper had evidently been read, and a discussion was progressing which rather puzzled me until I remembered a certain proverb in connexion with female grand-parents generally.

The Chairman was just saying that he was not so certain as Mr. (I didn't catch the name, but say Blank)—not so certain as Mr. Blank that the small end of the egg was the proper point from which to extract albumen, for he recollected that an old relative of his own invariably applied her lips to the larger end.

Mr. Stars had a few words to say upon the possibility of sucking both ends of the egg at the same time, and said them.

The Chairman said to a philosophical mind there could be no doubt of the fact.

Mr. Ox said he thought there would be some difficulty in applying the lips to both ends of the egg at the same time.

Mr. Blank explained his previous remarks, and said that by moving the head from side to side it might be accomplished. He denied that you could suck up and down.

The Chairman thought one *could* suck up and down at the same time.

Mr. Blank said there was a proposition in Euclid which was indisputable, viz., that two and two made four.

The Chairman said that if you added nothing to two you might make twenty, when two and two would be twenty-two; but thought these purely scientific questions hardly worth discussion.

Mr. Dash sucked an egg.

Mr. Yous thought it very strange that they should have to discuss sucked eggs.

Mr. Ochhone thought there was some misunderstanding on one point: he thought the taste of the albumen ought to govern them.

Mr. Blank thought everybody was botheration and conglomeration.

But I merely quote the words of these speakers to show how worthy of appearing in print these meetings of the Grand-parent Society are.

I am, yours, &c., PAUL PRY.

Kew Rye House, Nov. 21, 1860.

P.S.—A friend informs me that it was not the point of *suck*, but the "point of *sight*"—not *sucking* up and down, but *seeing* up and down at the same time, that was discussed. However, the difference is by no means material.

P. P. P., and P. of P. K. P.

ANSWERS TO CORRESPONDENTS.

Erratum.—In Mr. Hughes's paper on the mounting of lenses, which appeared in our last, the first and fourth diagrams were accidentally transposed by the printer. It is, however, a matter of but slight importance, as the *letters of reference* indicate correctly the several diagrams given.

*** Every now and then we receive an extra number of letters, asking for private replies. We have to repeat constantly that we cannot give answers to photographic queries, except through the medium of the Journal. It is not reasonable to ask for such; and we take this opportunity of stating that any postage stamps that may be enclosed, in order to *force* a private reply, will be confiscated without remorse.

H. Hopwood.—You will find the question discussed in the present leader.

Received with Thanks.—P. Le N. Foster.

Micro-Photo.—Undoubtedly, if you supply also a microscope with which to view them; but not otherwise.

J. Blackwell.—Your fault is, insufficient washing after the albumen. Use plenty of water, and the markings which now trouble you will disappear.

R. F.—We would with pleasure afford you the opportunity you desire if you were in London at the time. Possibly you may be able to attend on a future occasion.

Theta.—Put a little acid into your sensitising bath for albumenised paper. You may add alcohol, if you desire it.

Amateur Mechanic.—A piece of *clean* yellow deal (free from knots) is as good a material as you can possibly use for making a tripod, particularly if varnished; it is strong, rigid, "*stands well*," and is not heavy.

Multum in Parvo.—We do not perceive what real gain there is in your proposed arrangement, so far as your description explains it. If you like to send a sketch we will examine it.

Tyro.—You should make yourself acquainted with the elementary principles of chemistry. You will find many things in photography very difficult to explain unless you have some knowledge of the laws and phenomena of chemistry.

Novice.—You had better procure the little manual, by Hennah, on the Collodion Process, published by Knight and Co., Foster Lane, Cheapside, London.

J. M.—Your bath is too acid; rectify it by the addition of oxide of silver. It has most likely become acid by the use of collodion containing too much free iodine, which is apt to be the case when *old* collodion is employed, as you say you have been doing.

A Rifleman.—The ranks of riflemen have been swelled by many photographers; it is, therefore, but "poetical justice" that we should gain a few recruits from the riflemen. Inquire amongst the members of your corps, and we have little doubt that you will find one or more who can introduce you.

Lloyd Chapman.—We cannot perceive anything unreasonable in Mr. Hughes's remarks, which were expressed at one of the meetings of a London Society; and, as the official organ of that society, we simply recorded what took place. The anonymous extract from a letter which you include in your communication, though perhaps admissible in an advertisement, would be misplaced in our columns.

Jas. Kendall.—For the plain collodion, take pyroxyline 90 grains; ether, s. g. 0·723, 6 fluid oz.; alcohol, s. g. ·816, 2 fl. oz.; alcohol, s. g. 0·800, 1 fl. oz. Of the preceding, take *six drachms*, and add to it *two drachms* of iodising solution, made thus, namely:—Alcohol, s. g. ·816, 2 oz.; iodide of potassium 16 grains; iodide of cadmium 13 grains; bromide of cadmium 5 grains. Your sensitising-bath should be made of very pure nitrate of silver, re-crystallised twice, or even thrice, and should be very nearly neutral. Your communication shall appear in our next.

R. T. D.—You are not likely to obtain much greater sharpness (if any) with calotype paper negatives than the specimens sent by you. They are by no means bad of their kind, and calotype is only fitted for large-sized portraits. The front lens of an ordinary portrait combination is *not* the best adapted for landscape work. It is not necessary to have the lenses of a stereo-camera for landscapes arranged to vary their distance. You can always obtain any amount of difference in point of view, when desirable (if ever), by shifting the camera and exposing one half at a time.

Fog.—1. You have simply added a slight excess of the carbonated alkali. Remedy the defect by adding, drop by drop, a little dilute hydrochloric (muriatic) acid, shaking the mixture between each addition, and you will find the cloudiness disappear.—2. You should not attempt to remove spots on your brass work by means of brickdust, which only scratches off the lacquer, and makes matters worse. You had better get your mounting re-lacquered; and if needful, on another occasion, a damp cloth, followed by a dry leather, will be your mode of cleaning.

A Constant Subscriber.—1. We have had no personal practical experience in the Daguerreotype process, but we believe that the tarnished plate can be renovated by immersing it in a weak solution of cyanide of potassium, washing in distilled water, and then drying over a spirit lamp, with the usual precautions in drying a Daguerreotype plate.—2. Positives are not capable of conversion into good negatives, especially after being dried; but, perhaps, the best method is by covering the plate (after having previously moistened it all over) with a solution of perchloride of mercury. It then becomes whitened all over. Wash copiously and freely; drain slightly, and then cover with weak hydrosulphate of ammonia, which turns it of a brownish hue; finally, wash freely and dry.

A. J. B. (Halstead)—Your annoyance is a case of partially *reversed action*. The cause may be found in the concurrence of several influences tending towards the same direction, namely, organic matter in the bath (acetic acid, for instance), the impact of *faint* white light before exposure, or during exposure, or, what is still worse, *during development*: the addition of a minute portion of hyposulphite solution would be apt to produce it, though we do not anticipate this in your case. Commencing to develop, and then before any picture appears washing off, and again developing, will also produce it. Sometimes very protracted exposure in the camera will cause it. The probability would seem to us that, in your case, the dark room is in fault; the yellow material protecting your window has probably faded, and lets in a little ordinary light, which, if the development be long about, would be very apt to produce the defect.

A. G.—1. How is it possible for us to indicate who was meant by No. 1 in the reply to which you refer? We do not keep letters from correspondents beyond the time when they are answered, or we should by this time have a tolerably large room full of them. The number referred to a list, but what names were contained in that list we do not now know. You have also misread the reply which we gave. We stated nothing like what you have imagined, but simply asserted that by taking A instead of B the inquirer would accomplish his object with an exposure of fifteen seconds instead of twenty seconds—the letters A and B standing for two lenses about which he made inquiry for a certain specified object.—2. Your roller does not act upon the same principle as the lithographic press.—3. Fothergill.—4. If you have the middle lenses, we do not perceive what "fitting" they require, as they are already adapted to their proper place; but, at any rate, if you send them to any one, you had better do so to Mr. Lloyd Chapman, 27, Broad Street Buildings, London, the authorised agent of the maker.

Curious.—The small quantity of nitrate of silver would act very injuriously. Phosphate of soda is not an alkali, but a basic neutral salt. Chloride of gold is, in fact, a terchloride with an excess of hydrochloric acid; and it is of the utmost importance in Lyte's process of toning that it shall be neutralised before adding it to the phosphate of soda, otherwise that salt is partially decomposed. The neutralisation of the gold salt is very readily accomplished by adding carbonate of soda, thus converting the former into a double chloride of gold and sodium, and setting free the carbonic acid, *which, being gaseous*, disappears from the liquid, whereas with the phosphate of soda the phosphoric acid would remain. The hyposulphite of soda does not attack the gold (at least to any injurious extent), which is substituted for the silver in toning; but, if added to the toning bath, it is apt to combine with the reduced silver, sulphuretting it, and thus preventing the action of the gold thereon.

R. G.—We regret exceedingly to learn from you that the amateurs in your locality are not communicative. It displays a spirit of illiberality that would not be found in the metropolis. Your specimens are very commendable so far as manipulation is concerned, though not perfect even in that respect; but artistically they are atrocious. If you were to fold the portrait of the lady longitudinally, one-half would exactly match the other. You have not an atom of shadow, and consequently your picture looks as flat as a pancake. Arrange your sitter so as to let the light fall more on one side than the other; let the eyes be directed to some object towards one side or other of the camera—not staring straight at it; let the pose be natural, and it will most likely be graceful. The gentleman, though not so symmetrical as the lady, is far worse, because more constrained and rigid. A full face very rarely looks well in portraiture, and *never* when the whole body is likewise turned towards the spectators. You will generally find that what is called three-quarter face looks best. You little know the demands upon the time of an editor, or you would not ask for a specimen. We recommend you, however, to procure one from Messrs. St. George and Co., 31, Gloucester Place, Kentish Town, N.W. They are photographic printers; and we saw recently in their possession some proofs of card-portraits beautifully toned, and in which the figures were gracefully posed. We have no doubt that you can obtain, at moderate cost, exactly what you require from them.

Received.—Thos. G.—T. S. D.—Watkin—R. T. D.—A. M., and W. Strudwick.

*** We have received such a mass of valuable matter from various correspondents that we are compelled to postpone a large portion until our next, notwithstanding we give in this number eight extra pages of matter. We have to crave the indulgence of many whose contributions are marked for insertion or actually in type.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 132, Vol. VII.—DECEMBER 15, 1860.

With each copy of this number of the Journal we present an Almanac for the year 1861, adapted for carrying in the pocket-book, and containing many useful photographic formulæ and memoranda, which we trust will be found handy and convenient for consultation at any moment. With it we would offer the "compliments of the season," but we fear that we run some risk of being asked whether we mean umbrellas, goloshes, and top-coats.

Truly the year now passing away has been one unprecedentedly antagonistic to our art as regards the weather; but, according to the old saying, "when things are at the worst they must mend:" we hope for a better future. But if the practice of our art has been impeded, we cannot say the same of its literature: our societies have been unusually active, and our Journal full to overflowing. The latter may be a consequence of the former.

In order to meet the constantly increasing demands upon our space, the publisher has not hesitated, when requisite, to give several extra pages of matter; but so frequently has this concession been demanded of late, that the exception became the rule, and upon one occasion when we managed to dispense with it the circumstance elicited an expression of surprise. With the extra matter, extra expense to a large extent has been incurred; but subscribers have not been taxed in any way to meet the outlay: casual purchasers alone, when resident in the provinces, have of late had to pay an extra penny per number. We find that we have now reached a point when we are demanding still further extension of space. But our hitherto uncomplaining publisher is at length obliged to remonstrate: forbearance has its limits, and we have too far o'er-stepped its bounds.

We are unwilling to check the tide of photographic literature, which we believe has afforded pleasure and instruction to all concerned, and therefore it has been found necessary for the future to raise the price from threepence to fourpence per number in London and Liverpool, in accordance with the price now charged elsewhere—a change to which we hope and believe few of our readers will object, as they certainly receive more than a *quid pro quo*.

The subscription to this Journal in future will, therefore, be—for unstamped copies, 8s. per annum; for copies to go free by post, 10s. per annum,—*payable in advance.* Where credit is demanded or taken, 10 per cent. additional will be charged.

"Behold! how great a matter a little fire kindleth!" Who could have predicted that a quiet question, put by a quiet member of a suburban photographic society during a discussion on the *construction* of photographic lenses, would have been the cause of such a "hubbub" as that to which it has given birth?

In our report of the October meeting of the South London Photographic Society (page 319), we find one of the members, when commenting upon a paper that had been read by Mr. Hughes, employed the following words, viz.:—

"With reference to the use of the bayonet joint in Derogy's lenses, he did not consider that it would make the axis of the lens, when reversed, so true as the screw-joint. Every lens ought to be inserted in the *cell whilst the other portion of the brass-work was in the lathe,* so as to cut the thread of the screw and the cell at the same time. The slightest thing would throw the axis out."

After the preceding, several other remarks were made relative to other points in connexion with the lenses before the meeting, when, returning to the question of centering, a member asked "how they could tell when the axis of a lens was central?" to which the reply was, "*that was a trade secret—one of the important secrets only known to a few.*"

In our leading article we noticed this singular reply, and explained *the method in actual use* for centering lenses during their construction by two of the most celebrated English makers of photographic lenses, and all the first-class makers of microscopic object glasses; and we may remark that to centre the former is mere child's play as compared with the latter, which not unfrequently contain as many as eight and sometimes even nine distinct lenses in the combination. We stake our reputation on the accuracy of the assertion which we made, and are sceptical about any superior method being known for this purpose, notwithstanding the mystification attempted at the last meeting of the same Society to which we have already referred—a report of which appeared in our last, at pages 533 and 354, and to which we request our readers' attention.

Our good friend, the President of the Society, evidently tried to "let us down easily," by calling our description a *rough* method, and intended only to apply to view lenses; but we repeat that no such limitation was contemplated by us, and that the method described is that exclusively in constant actual use by opticians of the highest reputation for compound lenses of all kinds.

It has been sought by the gentleman upon whose reply we commented to convert the question into one very different to that recorded by our reporter, viz., "how photographers could tell when a portrait combination is properly centered?" But a simple reference to the context refutes this interpretation; and if it did not, the reply would have been to such a question irrelevant. There is no individuality in the question—no special emphasis *ad hominem*, "how do *you?*" &c., as implied by the non-content at our explanation in his subsequent animadversions. It is easily enough ascertained by photographers with sufficient accuracy whether their lenses be centered or not, by viewing the flame of a candle through the lens, and making the nearest reflected image (of which there will be as many as there are surfaces) eclipse all the rest: if any will not come into the general line, those surfaces which reflect them are ex-centric as regards their axes. Again, by viewing the flame as before and unscrewing one of the combinations, the flame will appear to "wobble" if either be not centrical. These, however, are but

rough tests—still quite enough for the generality of photographic lenses when already made.

We find on reference to the records of the discussion (p. 353), the mild (!) assertion that "it *frequently* happens that not more than *one* lens out of *six* is centered properly," &c. Again: "There are *two* makers whose lenses are properly centred; hence I infer they know this trade secret." We do not know what interpretation most readers would place upon these words, but to us it certainly appears intended to convey the impression that there are *only two* manufacturers of lenses besides the speaker *who understand their business*. But as we cannot suppose that the speaker really meant to make any such preposterous assertion, we can only fall back upon our previous conjecture, and, notwithstanding his disclaimer, come to the conclusion that he really was joking after all.

In conclusion, if the gentleman who has necessitated our making these observations feels himself aggrieved, and desires to reply, we freely place our columns at his service, and give him *carte blanche*, not only to say what he likes, but also to have the last word. "*Vive la liberté!*"

We cannot forbear calling the attention of our readers to the very valuable and interesting communication of our friend and coadjutor, Mr. Hardwich, being No. 15 of his "Photographic Comments," in which he details the result of his examination of half-a-pound of impure nitrate of silver, procured by him in consequence of some remarks by "S. H.," published at p. 242 of the current volume.

There are two points in the communication above referred to especially worthy of being noted, having a very important bearing upon the practice of the collodion process. The first is the fact that negatives taken upon plates sensitised in a bath prepared from the contaminated nitrate of silver, exhibited all the appearances usually attributed to the presence of excess of free nitric acid in the bath—the actinic action being greatly retarded, and the resulting negative weak and poor, while it is noteworthy that precautions were taken to neutralise all nitric acid that might have been present. From previous experience it was suspected that the defects were due to the presence of *organic matter* of some kind, and subsequent experiments confirmed this conjecture.

At the first blush it might appear strange that the presence of organic matter, which usually adds materially to the density of a negative developed under its influence, should in the instance mentioned tend to weaken it; but on considering carefully how the seeming discrepancy can be reconciled, Mr. Hardwich is of opinion that in the case of the impure nitrate of silver the organic matter is probably in a state of oxidation, and in those where it acts as an intensifier the reverse condition obtains. Be this as it may, the fact of the impurity consisting of organic matter is unquestionable, no less than its deteriorating influence. The other point of moment demanding special record is the antidote for the bane already noticed, viz., that by the addition to the collodion of a bromide as well as the iodide which it already contained, a fair picture was capable of being produced, even with the impure bath, which when the simply iodised collodion alone was employed failed to allow of the impression of any of the details in the shadow. These are facts that by the intelligent operator should never be lost sight of, especially when we reflect that, according to the reliable testimony of Messrs. Hopkin and Williams, no less a proportion than 25 per cent. of commercial nitrate of silver contains so much organic matter as to render it unsaleable by the conscientious dealer.

While on this point we may as well correct a typical error which was accidentally overlooked in Mr. Hardwich's paper. At line 17, p. 343, "nitrate of silver decomposed" should read "nitrite," &c.

We have to mention the formation of a new Photographic Society which has recently been called into existence at Bradford. The inauguration meeting was held on the 2nd ult., and the report of the first ordinary meeting, which took place on the 5th inst., will be found under our usual heading.

An advertisement, which will be found in the usual column, announces that all pictures intended for the forthcoming Exhibition of the London Photographic Society should be sent to the Gallery, 5, Pall Mall, on the 27th instant.

ON PRINTING, TONING, AND FIXING PHOTOGRAPHIC PRINTS.

By A. Macnab.

[Read before a meeting of the City of Glasgow and West of Scotland Photographic Society, on December 6th, 1860.]

In accordance with the resolution passed at our last meeting, I now beg leave to open the discussion on the subject of *Printing, Toning, and Fixing Photographic Prints.*

From the papers published lately in The British Journal of Photography, from the able pen of C. Jabez Hughes, and also from those recently read before this Society's meetings by Messrs. Stuart and Ewing, one might readily suppose the subject is now pretty well exhausted, and but little remains of general or particular interest.

Aware of the difficulty of keeping alive or sustaining an interest at the fag end of a subject already shorn of its strength, I purpose going through a few experiments upon the recovery of silver from the washings of prints, adding, by the way, a strong recommendation to every one largely engaged in printing, *i. e., to make their own chloride of gold.*

Before doing so, however, allow me a few remarks of a general nature, *en passant.*

That the subject is full of interest in a practical point of view few of us will I presume question, and the more light brought to bear upon it the better—an operation simple to look upon, yet with results that are striking and decided, whose success is the necessary consequence of years of anxious labour and thought.

Although I may not be adding my mite to the general stock of knowledge already possessed by the members of this Society, I crave your indulgence to any statement or remark that I may make to-night at variance with those already advanced. We may err in our opinions and manipulatory details; but it remains for you to judge of, and adopt, the better way. My scraps of experience, such as they are, are given to you in sincerity and candour, undisguised by technical terms, and wholly unvarnished. It is but a stale repetition of the old proverb, that "doctors differ," and why not photographers. The practice of our noble art embraces a wide field for thought and research—new and ever varied forms recurring to note the different phases they are ever assuming, and appropriate the happy accident of some hitherto undeveloped property of chemical combination. These ought to be the first care of every one who has the progress of his profession at heart.

It forms no part of my purpose to enter upon the details already discussed in the former papers—such as the selection of paper (which, by-the-by, cannot be too carefully done), washing the dishes, strength of silver, manner of laying down the paper, time of floating, and how to hang up and dry. All this has been fully described. I would observe, that if the paper be highly albumenised, and possess a very highly glazed surface, it will frequently appear as if it were greasy after its removal from the silver bath. The silver first runs in parallel lines: after a time they break up into small spheres, and, if allowed to dry, would produce a mottled spotty picture, as though it had been sprinkled with rain drops. This is easily prevented by allowing the paper to drain well, and taking a small piece of French filter paper, folded like the blade of a fan, with which carefully go over and break all the dew-drops—if I may so express myself—as the paper has all the appearance of *perspiring* freely. By this simple method good solid prints will be produced. Neglect this simple precaution, and a hundred to one but your prints are covered with spots. I am particular in calling your attention to this, as I have not been troubled with it when the paper has been open or porous.

For negatives thin and full of half-tones I prefer highly glazed albumenised paper, and printed in bright light. This frequently gives good results, when otherwise they might prove failures. For negatives rather dense, giving pretty decided contrasts,

I prefer using an open, porous paper, and printed in slow light. Soft and often beautiful prints are to be obtained in this way by a little management and general precaution.

The prints once printed are carefully preserved from the light: they are then first floated upon clean water for some ten or fifteen minutes, and then changed to another dish, and floated for say ten or fifteen minutes *longer*. They are then removed to a *third* dish, and immersed for some time, previous to being toned. I do not require here to recapitulate this part of the operation, so fully discussed in former papers.

It is of importance that the gold should be of first-rate quality. I have had great difficulty in purchasing gold which gave me as fine results as the chloride of gold of one's own making. It is much cheaper, by more than one-third; and goes a greater way in toning, and gives richer tones. You can purchase pure gold for twopence per grain. Fifty-six grains in Australian nuggets will cost 9s. 4d.: this will produce chloride of gold of about eighty-six grains, which, at twopence per grain, will be 14s. 4d., showing a clear saving of five shillings, besides having a genuine article that can be depended upon.

I may here give the formula for making the chloride of gold, as contained in Hardwich's *Chemistry of Photography*, pp. 451, 452:—

"This salt is formed by dissolving pure metallic gold in nitro-hydrochloric acid, and evaporating at a gentle heat. The solution affords deliquescent crystals of a deep orange colour.

"Chloride of gold, in a state fit for photographic use, may easily be obtained by the following process:—Place a half-sovereign in any convenient vessel, and pour on it half a drachm of nitric acid, mixed with two and a-half drachms of hydrochloric acid, and three drachms of water; digest by a gentle heat, but do not *boil* the acid, or much of the chloride will be driven off in the form of gas. At the expiration of a few hours add fresh *aqua regia*, in quantity the same as at first, which will probably complete the solution; but, if not, repeat the process a third time.

"Lastly, neutralise the liquid by adding carbonate of soda until all effervescence ceases, and a green precipitate forms. This is *carbonate of copper*, which must be allowed several hours to separate thoroughly. The chloride of gold is thus freed from copper and silver, with which the metallic gold is alloyed in the standard coin of the realm. The solution so prepared will be *alkaline*, and, consequently, prone to a reduction of metallic gold: a slight extra quantity of hydrochloric acid should therefore be added, sufficient to redden a piece of immersed litmus paper."

The recovery of silver from the washings of the prints—to be rendered easily available—is another important point. There are several ways by which this can be done: by copper, by hydrochloric acid, by salt and liquor of potass, or caustic potass. The two last I prefer, from the lesser trouble connected with the recovery of the silver, which can easily be reduced and re-crystallised

ON A NEW METHOD OF DECOLORISING THE ALBUMEN SILVER BATH.

By Mr. Tunny.

[Read at a meeting of the Photographic Society of Scotland, on Tuesday, Dec. 11, 1860.]

All who have been accustomed to print upon albumenised paper must have felt the greatest inconvenience to be a rapid deterioration of the silver bath, rendering the prints mealy and rather scummy upon the surface. This, to a certain extent, has been remedied by the use of animal charcoal and kaolin. No doubt the filtration of the silver bath through these substances frees it from colouring matter; but the large quantity of phosphate and carbonate of lime they often contain renders the bath strongly alkaline; and, also, the strongest bath will, after their use, be found to be very much diminished. The practical photographer, who weighs out his silver by ounces instead of grains, is very sensitive to this fact. In order to lessen the one and remove the other, I instituted a number of experiments for the attainment of this object; and I am glad of this opportunity of informing the members of our society that I have been successful, not only in clearing the bath from its inky blackness, but also in imparting to it the property of permanently retaining its restored crystalline purity.

I have here a bottle of nitrate of silver solution, which has been used for the purpose of exciting albumenised paper. It is not so black as I would have liked it for this experiment; but sufficiently so, I dare say, to illustrate the ease with which it can be purified. The solution is slightly alkaline, as may be demonstrated by the test paper. I now put into this silver a drop or two of a *saturated solution of citric acid*.* A drop or two is quite sufficient for a considerable quantity of fluid. You will now see taking place a flocculent deposition, which is citrate of silver, and that this is nearly all re-dissolved by a little shaking. All that is now required is simply to filter, in order to have the silver as pure as when it was first made into solution.

It will be found, on examination of the filter paper, that there is nothing to be seen but a slight discoloring of the paper. Now to test paper it is slightly acid, which is the best condition of bath to give vigorous prints. It will be seen that paper sensitised on an alkaline bath will be found wanting in vigour, when compared with prints which have been prepared by a slightly acid bath.

In connection with this, I will, on another occasion, take an opportunity of bringing before you a modification of the ammonio-citrate of silver bath for sensitising albumenised paper, which gives a beautiful tone of colour, even without the use of gold. And here I would just mention to those who have not had much experience in toning with gold, that it is of the utmost importance in successful toning not to have the bath strongly alkaline: all that is required is that it be merely neutral. All the prints I have sent out for the last ten years have been toned with a neutral gold bath. As to the permanency of prints, no matter how they are toned, if they are not sufficiently washed with boiling water, I have great fears of their ultimate destruction. I think this fact cannot be too often brought before the professional photographer, as I fear, in many cases, *permanency* is too often sacrificed to a desire for black tints.

* We have an impression that Mr. Tunny has been forestalled in this application of citric acid, the same having been brought before the London Society about twelve months ago, if our memory be not at fault.—Ed.

A FEW WORDS ABOUT THE MANAGERS, EXHIBITORS, AND CRITICS, OF OUR PHOTOGRAPHIC EXHIBITIONS.

By Alfred H. Wall.

Let him not degenerate from serving Art, the Queen,
To a preference for her handmaids, the Sciences.
The Bee and the Worm excel him in diligence
And mechanical craft; the Seraph in knowledge;
But art is man's alone.

Schiller's *Poem of the Artists.*

I am addressing more particularly the members of our Photographic Societies, who, from a pure love of our art, and an unselfish desire for its improvement and advancement, have given up their time to meetings, and expended their money in experiments, in a manner as honourable to themselves as it has been advantageous to the profession at large; for I am convinced that it will only be necessary to publish any hints tending to the advancement of the art and science of photography to secure for them due attention and impartial consideration.

A recent writer in a contemporary, with ungracious, ungrateful, and unthinking smallness, attempts to sneer at these societies, and seems to think that the fact of each gentleman speaking about a subject he best understands, or, as he says, playing upon his own particular "brass kettle," deserves reproof; whereas the great evil in our societies will be found in those who, like the writer in question, occasionally insist upon speaking on subjects they know nothing about. But this is apart from my subject.

The experience of modern times has fully demonstrated the great power and value of our periodical art exhibitions. Their history would take us back comparatively but a few years; and yet how rapid has been their growth in importance, power, and number.

In 1768 one picture exhibition only, that of the "Incorporated Society of Artists," could be found in London, and this solitary institution was by no means of a great or flourishing character. From this, however, sprang others which, gradually improving from year to year, have done more for the spread of good art and public taste than can be traced to any other source; and we well know British art now occupies a higher position than it ever claimed before, and at the same time art expositions are more successful and more numerous than they were at any other period. More pictures found purchasers, and more visitors attended our exhibitions, during the last art season than could be recorded of any previous year, and at the same time the Royal Academy secured the largest sum its exhibition has ever yet produced, viz., £11,000.

Not only is this very encouraging to all lovers of, and believers in, art, but it shows how intimately the progress of art is connected with that of our exhibitions.

I wish to impress the above facts earnestly upon the members of our photographic societies generally, but more especially upon such as belong to the older or, as it is commonly called, the parent society. To their generously fostering care is entrusted the welfare,

education, and future character of our beautiful infant art, the development of which is, as I have tried to show, in no small measure dependent upon our exhibitions.

When the parent society—culpably neglectful of the artistic branches—has spent its time in studying to improve the mechanical, chemical, or optical appliances of photography, and begins to contemplate preparing for the annual exhibition, it should be far from regarding it with the ignoble spirit of a showman, anxious only for the shillings it will bring in; but should remember how potent for good or ill the influence it will exercise must be upon the public mind. The old proverb says, "Give a dog an ill name and hang him;" and, of this we may be sure, that directly any art becomes degraded in public estimation it speedily sinks even below the level assigned it.

One feature of our exhibitions has hitherto been neglected, viz., the proper classification and arrangement of the specimens, so as to illustrate the wide range of applications to which photography has extended. It does not suffice to advertise an appeal to exhibitors, and then merely hang up their productions, with as little reference to their widely varying characters and pretensions as would be displayed in promiscuously jumbling together a mass of the most heterogeneous articles; for such a process must be as injurious to the art itself as it is unjust to exhibitors at large.

Let works which aspire to the character of artistic productions be subdivided into their various branches, and grouped together. Let other specimens, valuable as purely scientific agents, whether as illustrative of geological principles—of medical, botanical, or chemical studies—of comparative anatomy, archeology, architecture, or other scientific pursuits,* receive the same treatment, and the result must be in every way advantageous to the public, the society, the exhibition, and to photography itself.

If photography be really an art—as is now more generally asserted and believed—why should it be treated as a something purely mechanical, or purely scientific, and exhibited to the world with no more care or study than is thought necessary to opening the door of a common show upon some wonderful giant or dwarf, or some ingenious piece of mechanism? The mere fact of this exhibition existing, as it does from year to year, and being supported as it is by those who chiefly value it for its pictorial attractions, prove the necessity for this classification of the specimens exhibited, and set the seal to its pretensions as an art exposition.

In creating competition, and raising the standard of taste by the organisation of the London Exhibition, the parent society founded a just claim to our hearty thanks, and did more for the advancement of the art and the welfare of its professors than has been effected by all the many papers and discussions brought forward at its subsequent meetings. But the mere establishment of this exhibition will not prevent its decline, if it fail to keep pace with the improvements of the day

Picture buyers look to our picture exhibitions for their purchases, because, by carefully excluding all works below a certain standard, such institutions have acquired a character which is in itself a sufficient guarantee for the artistic quality of any pictures selected from their collections. Now, there are very few who will deny that certain photographs appear each year in *our* exhibitions that are as discreditable to the art as to their producers, and which tend to lower the dignity, decrease the utility, and mar the progress of photographic exhibitions. Every work should have its individual and relative merit, according to its classification; and the committee appointed to make choice of and hang the specimens should be composed of the best qualified members of the society concerned. Thus will patronage be directed into the best channel, the best reward await the highest merit, and the best interests of the art our societies were publicly organised to advance and support be properly and nobly served. There is, I know from professional experience, much carelessness among exhibitors as to the character of the specimens sent for "the exhibition;" many sending not their best and some their worst, because most easily spared, specimens for the purpose. That those who so acted were shortsighted and foolish to their own interests is true enough; but, nevertheless, so stands the stubborn fact, and I can but point out where the responsibility lies. You, as well as I, have doubtless seen bad specimens exhibited in the Societies' rooms by those who were exhibiting very superior things elsewhere. And I do not think it can be doubted that the positive refusal of such contributions, by a society having a position in public estimation which rendered its approbation a matter of commercial importance, would soon bring forth others of a very superior character.

* There will, of course, be various other subdivisions.

Having thrown out these few suggestive hints, humbly, and by no means in a spirit of dogmatic criticism, let me add a few words for our exhibitors.

Nothing contributes more effectually to create amicable but earnest emulation among the votaries of art than competition. It is true that this is very frequently a sharp spur which pricks us up somewhat painfully; but we get on the better for it, and reach our goal the sooner. The opportunity of making a comparative study of contemporaneous productions is of the utmost value to us all, and it is our duty to aid the organisers and managers of such institutions with our very best works.

The ardent cultivator of his art, working without competition, and consequently growing indolently complacent and comfortably self-satisfied, may grow somewhat peevish, snarlish, and impatient of his own progress when he sees the inferiority of his specimens made so painfully apparent by contrast with a Fenton's, a Rejlander's, a Williams's, or a Wilson's; but, if he be made of the right stuff, out of such feelings must arise that manly and noble spirit of perseverance and emulation which will bring about a stage of perfection and success he would not otherwise have aimed at attaining. This bringing together of works executed by the most successful operators in the country keeps us moving, and when you "halt" you must inevitably soon find yourself in the rear of your advancing comrades.

Impertinently supposing that you, my dear reader, were a very egotistical personage (which of course you are not), dearly loving to display, when occasion served, your various virtues and charms, I venture to say that from this fact would arise one of two things: either you would be treated with well-deserved contempt for advancing pretensions to qualities not in your possession, or what I have termed your egotism would be duly admired and venerated as the lofty self-respect and dignity of conscious genius. Now, instead of the egotistical personage with or without a proper foundation for your published pretensions, suppose yourself a society making similar claims, and permit me (addressing you as a society contemplating a photographic exhibition, and having a committee about to appoint a sub-committee for selecting and hanging the specimens) to remind you how important a task you have undertaken, and to hope that the proper classification hint may be taken, that inferior productions may be declined, superior works not only invited but actively sought after (many excellent works are lost to sight through the timidity or modesty of amateur operators*), and above all that its pictorial capabilities be prominently displayed, inasmuch as upon the latter must be founded its chief claim to public patronage.

Before quitting my subject, there remains another class of personages in connexion therewith to be noticed—viz., photographic art critics.

Although, among the writers upon photographic exhibitions, we have those who criticise ably enough the optical, chemical, mechanical, and manipulatory qualities of the works collected, I do not remember any two critiques in which photographs have been criticised as pictorial productions.

Art critics have, upon the whole, obstinately refused to recognise photographs as works of art, and have, sometimes with sweeping blows and hostile denunciations, and at others with sneering condescension and patronising charitableness, aimed at thrusting it into the ignoble class of mere mechanical processes, or treated it as a purely scientific pursuit. By these the efforts of our more aspiring and artistic operators have been frequently discouraged, the public estimation of the art more or less lowered, and the character of a successful photographer considerably depreciated. Having to war against these is another good and sufficient reason for endeavouring to elevate the intellectual character of exhibited productions.

Again, it seems to me, from a perusal of the critical remarks on these expositions, published in our photographic contemporaries year by year, that the opposing critics could have no more able assistants than the supporting critics. The latter's writings display such a lamentable ignorance of imitative art and of a picture's most elementary principles, and presume so evidently upon a superficial acquaintance with a few of the more common art techni-

* I hear many complaints from professional exhibitors with regard to the unwarrantably great damage done to their productions before their return, &c. One gentleman, whose word I can rely upon, informed me that he had lost a complete set of stereoscopes which were exhibited last year. Another, that his frames, of a costly character, were returned in an almost worthless state, and so on. Now, although professors may set the advantage gained against such losses, it is clear that amateurs cannot do so, and that the exhibition must from this cause alone lose some of the best pictures in the country. I know that some small damage to the goods of exhibitors can scarcely be avoided; but it is not common with other institutions to do so much damage, and I do not think it by any means impossible to avoid such altogether.

calities, or their high reputation in the scientific branches, that one can but grow angry and annoyed in perusing their grossly erring tissues of dogmatic ignorance or impertinent twaddle, and cry aloud "preserve me from my friends!"

The reason of all this is that we have given undue prominence to the mechanical and scientific branches of photography and neglected so thoroughly the artistic. The higher department needs cultivation before photography can assume its most prosperous and thriving condition, and the study of art should now blend with that of lenses, chemicals, apparatus, and processes.

We want our optician's labour to remedy serious defects still existing in our lenses; we want our chemist's wise head and noble knowledge to teach us how to translate nature's *chiaroscuro truthfully* and perfectly; and we want our ingenious mechanic's skill and experience for the apparatus upon the efficiency of which so much depends. But do we not want also that gifted intellect which creates not only a language common to every nation of the world, but a language which speaks in the music of beauty and the eloquence of poetry—humanising and elevating with tender and loving influence the heart and soul of man? When we have all these, how powerfully *then* will photography speak to the world through the rosy lips of our photographic exhibitions! That we *may* have this combination in one harmonious whole, heart, head, and hand must now be united in our work,—no more important branch of which exists than that I have now pointed out to our photographic societies, our photographic exhibitors, and photographic critics, in photographic exhibitions. J. Cameron tells us—

"Science for ever sees her limits fly:
A conquering power in transitory near,
The common world of common eye and ear.
Yet can *she* commune with the highest high?
Nay, she not seldom putteth out the eye
And chokes the ear that communes with divine.
She kneels not at the spirit's inmost shrine:
There is no Jacob's ladder in *her* sky!
Thine are the exalting functions, holy Art!
Thou cans't translate the soul to cloudless prime,
Bring down from realms that know nor time nor space
Pure apparitions that content the heart;
Thou fill'st the spirit with the peace sublime
Of who with God hold commune face to face."

ON THE WAXED-PAPER PROCESS.

By W. H. Leather.

[Read at a meeting of the Bradford Photographic Society, on Dec. 5th, 1860.]

As the Waxed-Paper may now be considered an old process, I wil will simply give in detail my present practice.

The paper I prefer is Marion's negative, which I believe is sized with some vegetable sizing; but English papers, which have animal sizing, have also been used. Any specimen of wax that is chemically clean will also do: I have hitherto used some prepared by myself from the honeycomb. Having ascertained which is the right side of the paper, I divide the sheet into four, and mark each quarter sheet with a pencil at one corner, on its right side. These quarter sheets give the size suitable for my camera, which takes pictures 10 by 8 in.; and I proceed to wax them in this manner:—I have a smooth half-inch deal board, 13 in. by 11 in., which I lay on the table; and on this I place a whole sheet of white filtering paper folded in four, which serves as a pad, on which I lay my sheet of paper to be waxed, right side upwards. I now take a common box smoothing-iron, moderately hot and perfectly clean, in my left hand, and go over the whole paper. I then take the wax in my right hand, and apply it to the side of the iron, which with my left hand I hold at the left top corner of the sheet, and only about half an inch on the sheet. As soon as sufficient wax has melted to form a wave, I chace it with the iron right across the paper, and commence again at the left hand lower corner, repeating the same. If any portions of the paper are still without wax, I bring the iron over them and apply the wax, going over the whole afterwards with the iron, to equalise the distribution of the wax. When all my sheets are gone through, I place another heater in the box-iron, rather hotter than the first, and I place each sheet separately within the middle fold of a fresh pad of blotting paper, and with considerable pressure well iron the pad and the sheet within, in order to take off all superabundant wax. The sheet should now present an even appearance, without any shining spots, and in this condition I store up my sheets, and iodise them afterwards as they are required for use.

Many iodising solutions have been recommended, all of which, I dare say, are good. I use the following:—

Iodide of potassium...15 grains		
Bromide.................... 5 "	to each oz. of water.	
Gum arabic................ 2 "		

I pour 12 oz. of this solution into a clean porcelain dish, 12 in. by 9 in., and immerse the sheets one by one, taking care that no air-bubbles intervene or attach themselves to the papers; and I let the whole remain at least an hour, occasionally moving and agitating the sheets. They are then taken out and pinned by one corner, to drain and dry. I prefer to iodise my sheets in a darkened room, though I believe this is not material. The only further attention I pay to them is to visit them in about a quarter of an hour, and touch the lower corner of each sheet with a piece of filtering paper, to remove the last drop of solution. When dry, they are ready for exciting, which is done by immersing each sheet separately in a bath composed of

Nitrate of silver......30 grains	To each ounce of
Glacial acetic acid, 30 minims	distilled water,

taking care that no air bubbles are allowed to remain, and occasionally agitating the dish containing the sheets. I prefer to excite only two sheets at a time; and after the second sheet has been four minutes in the bath, I take each sheet out and immerse it in a bath of clean common water, well agitating it for about a minute, so as to wash off the excess of the exciting bath. If I intend to expose the sheets the same day, this washing is sufficient; if more than one day intervene before exposure, it is necessary to wash again in a fresh bath of water as before. The sheets are removed from the water, drained for a moment, and each separately placed in a clean pad of filtering paper, to remove as much as possible of the moisture, and afterwards pinned up until the surface is apparently quite dry, when they may be placed in the exposing frame. The time of exposure varies from three quarters of an hour on a sunny winter's day, to ten minutes on a bright summer's day. The picture is developed by placing the exposed sheet in a bath of gallic acid for a few minutes, then, taking out the sheet, add a little of the nitrate bath to the gallic acid, and after well mixing these together, again immerse the sheet, when the picture gradually acquires the requisite detail and density. I find it is not necessary to use a saturated solution of gallic acid; but it is necessary to see that no crystals of gallic acid are allowed to get into the developing bath, as these are liable to cause stains. The developed picture is washed well in two changes of clean water, and I prefer fixing it in daylight, so that I can see when the yellow iodide is all dissolved out. The fixing bath is composed of hyposulphite of soda, six ounces to a pint of water, the whole of which I pour into a common salt glazed dish of sufficient dimensions, and immerse my sheets, removing them, as soon as the iodide is out, to a dish of clean water. They are then well washed in three or four changes of water (one hour to each change), then removed to drain, blotted off, and pinned up to dry. When the surface is dry they are exposed to a moderate warmth, so as to re-melt the wax; and this completes the process.

ON IODIDE OF SILVER.

By Dr. J. Schnauss.

(Concluded from page 300.)

I think I may be allowed to notice in this place a peculiar phenomenon, lately observed by several renowned photographers—viz., the blurring* of the blacks of the negative in a fixed direction. It cannot be produced at will. I, at least, have only noticed it three times. In the two first instances it happened that, on developing a portrait taken on a collodion strongly iodised with iodide of cadmium and some bromide of cadmium, by means of a solution of sulphate of iron, the deepest blacks—for instance, that of the hands, the collar, &c.—appeared blurred in a fixed direction, not sharply defined. The third time this phenomenon appeared with my usual collodion (iodised with ammonium and cadmium, but which also contains some bromides), the picture seemed almost over-exposed. The direction of the blurring was in all three cases the same—namely, that in which the silver flowed downwards in the slide, and (whether accidentally or not) that in which the developer was poured upon it.

In the two first instances I also ascertained the remarkable fact, that my collodion, iodised with cadmium salts, did not produce, as is usually the case, negatives of a reddish hue, very tender, and over-exposed in aspect; but, on the contrary, after a very short exposure, it produced sharp pictures of a deep-black hue and very intense. The pyroxyline had been prepared by myself at the heat of 55° (R), by means of nitre and English sulphuric acid; I had also produced the iodide and bromide of cadmium myself.

In a later experiment, in which the pyroxyline had been washed

* This appearance is known as "*halation*."—Ed.

with ammonia and then with distilled water, the phenomenon of blurring did not reappear, and the negatives were tender and of a reddish hue. May not this phenomenon of intensity have been produced by some acid in the pyroxyline, which evidently was also the cause of the blurring?

It is difficult to give any reason for the latter phenomenon. Until now, I believed it to result from pouring on too quickly a strong-acting developer. Other photographers, however, seem to trace its cause to the silver solution drawing down the plate during the exposure.

There are two important phenomena in connexion with iodide of silver which also partially indicate a modified condition of it. One — the least understood — is exhibited in what in England is termed "the reversed action of light." In France the images thus obtained are termed "amphi-positives."

The other phenomenon concerns the altered qualities of the + iodide of silver in a dry state, particularly in the inner part of the collodion film, as it occurs, for instance, in the "dry process."

Several photographers, among others Poitevin, De la Blanchère, and Schouwaloff, have lately taught us to produce this "reversed action of light" at pleasure. This action resides principally in the property of the + iodide of silver, imparted to it by, as yet, unknown causes of darkening under the action of the developer, even without having been exposed to the action of light, but not of so decided a black as that of ordinary negatives, but of a reddish brown, similar in hue to that assumed by negatives too strongly lighted in the first moment, under the influence of pyrogallic acid. But while the latter continue to attract the reduced silver, and are thus continually growing darker, the amphi-positive images appear to be deficient in this quality.

Working dry collodion plates has taught us that the dry photogenic film of + iodide of silver in connexion with the organic substance of the collodion, if not exactly less sensitive to the action of light, has far less power than the still *humid* + iodide of silver to assume the dark black tones required in a negative, even if from the latter, as in the dry process, all the surplus nitrate of silver has been washed off, and only put on again by immersion in the silver bath before the development. The cause of this consists in a different molecular arrangement of the film, as is evident in looking at a dry and a wet collodion plate. The wet film, after immersion in the nitrate bath, assumes a yellowish white colour, and is not transparent; whereas, the dry film, after being washed and dried, is nearly transparent. The first represents, as it were, the hydrated state, and the latter the anhydrous.

The collodion film, in consequence of its porosity, is very likely the principal cause of this phenomenon: still it is also possible that the + iodide of silver produced exists, at the same time, in a corresponding anhydrous or hydrated state. Chemistry, at any rate, teaches us that many solid bodies exist partly in the hydrated condition and partly in the anhydrous, and that the heavy oxides of metals must more easily form combinations in the former state than in the latter. For example, the yellow hydrated oxide of iron readily dissolves in dilute acids, while the red anhydrous oxide requires both stronger acids and the aid of heat. Therefore it is very natural that the whole process of developing takes place much quicker, and with more energy, in a wet plate than it does in a dry plate, since with the first there is an easier penetration of the film.

While the collodion film is drying on the glass plates a not inconsiderable contraction takes place, which may be readily observed in negatives on the edges of the glass plate, where the film will sometimes exhibit a perceptible shrinking to the extent of an eighth of an inch. This also explains the increased darkening in the negatives, after drying, in consequence of a contraction of the black silver molecules, which, as it occurs in every direction at the same time, results in a scarcely perceptible diminution; only if the cohesion of the film be lessened by adding too much water to the collodion, a very injurious cracking of the film takes place in the drying, whereby particularly the darks of the negative are riddled by an infinite number of small net-like cracks.

In the hydrated state the collodion film is much more easily penetrated by the liquids poured upon it. Therefore, in many photogenic processes of this kind—as, for instance, in the collodio-albumen process—there occurs not only a coating of the collodion film with albumen, but a more or less complete penetration of both substances.

On drying iodised collodion plates, which are coated with strongly iodised albumen, it is frequently observed that the whole film becomes perfectly transparent, the cause of which is, that the + iodide of silver is dissolved in the iodide salts (potassium, ammonium) of the albumen, and converted into — iodide of silver. When such plates are subsequently immersed in the second nitrate of silver bath, a decomposition of the — iodide salts takes place, and consequently an evaporation of the iodide of silver which has been dissolved; upon which the film again assumes its original opaline, almost untransparent, appearance.

In many "preservative processes," hygroscopic substances are employed with a view of preserving the hydrated condition of the photogenic film.

These agents certainly produce strong negatives generally much easier than can be obtained from a dried film. It will be interesting to pass in review all the various substances hitherto proposed as preservative agents for collodioned plates, as far as I can recollect them at present.

MINERAL SUBSTANCES EMPLOYED.

1. Nitrate of magnesia.
2. Nitrate of zinc.
3. Chloride of lime.

SUBSTANCES DERIVED FROM THE VEGETABLE KINGDOM.

1. Syrups (solutions of sugar of various kinds).
2. Wine (champagne).
3. Beer (brown stout).
4. Balsams, resins in great variety.
5. Glycerine (linseed).

SUBSTANCES DERIVED FROM THE ANIMAL KINGDOM.

1. Gelatine.
2. Metagelatine.
3. Albumen.
4. Honey.
5. Oxymel.
6. Milk.
7. Glycerine.

By the above list it will be seen that from the organic kingdom we are supplied with the principal ingredients of a frugal breakfast, as it may be composed of milk, eggs, beer, wine, and honey.

The series of preservative processes, all of which are but palpable modes of obtaining the same result by analagous means, has served one useful purpose—it has ministered to the vanity of a host of would-be inventors and discoverers; and from the readiness with which every crude idea finds its way into print, a temporary notoriety has been conferred upon the ingenious persons who have suggested them. Much ink might have been saved if the editor of some photographic journal had at first published a list of all known hygroscopic substances capable of being applied without injury to the collodion film. Any tyro in chemistry would have supplied him with as copious a list as we now possess, after the united efforts of some score of ingenious minds have, during the lapse of eight years, been devoted to the subject.

Of all the above-named substances, albumen and transparent gelatine command a preference over the others, which nearly all belong to *the sticky* series, or form a sticky coating on the plate, whereby they attract the dust and light particles of matter floating in the atmosphere, which exercise a very mischievous influence during the developing.

The only object of adding resin, or balsam, to collodion for the dry process, is to obviate the bad results arising from the contraction of the collodion as well as from the tearing and peeling off of the film.

STEREO-MANIPULATING CAMERA.

By Thomas S. Davis.

The special object of the Stereo-Manipulating Camera is to enable the tourist to produce stereographs by the wet collodion process without the encumbrance of heavy or inconvenient apparatus.

This invention essentially consists of a portable and commodious chamber and a light cone-shaped camera, having a rising front to carry the lenses. The chamber is capable of carrying the camera in its interior when packed, and has an aperture in front equal to the size of a stereoscopic plate, over which the cone slides when ready for use. Upon the internal side of this opening a frame is fixed, and a shutter is hinged to the back to enclose it in darkness. Immediately beneath the frame is a longitudinal stop, glazed with yellow glass, and fitted with slides in order to regulate the admission of light. Beneath this, and through the bottom of the box, a cloth bag is suspended to hold the nitrate of silver bath: over this a lid shuts for the purpose of excluding dust, light, or chance impurities. Upon the edges of the top and bottom of the box are hinged two

flaps, each half the height of the box: the upper one supports the black covering free from the hand, and the lower constitutes the table for the developing tray, and the two when closed protect the contents. The developing dish is made of tin, and holds over its centre a piece of wood, which retains the damp glass without slipping at a considerable inclination. By this simple arrangement the plate can be developed without fingering until it be thought necessary to examine it by the transmitted light, admitted immediately facing the operator. At the right hand side of the box there is an arrangement for holding three glasses to contain the developing fluid, water, and the fixing solution. The Stereo-Manipulating Camera is fastened in the usual manner to the top of the ordinary stand, and its elevation can be regulated to the height and convenience of the photographer. A curtain attached to the box answers the purpose of the focussing cloth, the completion of a light tight chamber when secured round the waist, and an outside wrapper to cover the whole when closed.

The apparatus is accompanied by a plate box, designed as a convenient arrangement for carrying wet plates without the risk of displacing the film. The boxes are made internally equal to the length of the plate, but about three eighths of an inch wider. Upon their longer sides four pieces of wood are to be attached a quarter of an inch distant from their ends: these pieces serve to retain a series of loose narrow slips, having raised corners, against the shorter sides of the box. By placing the wet plate face downwards upon a pair of these slips, it will be kept steadily in its place, and it will rest simply upon its four corners. Additional slips and plates can then be arranged alternately in like manner, and a number of pictures can thus be carried with complete security, and without the chance of the wet film becoming displaced by friction.

RESULT OF A SERIES OF EXPERIMENTS ON THE COLLODIO-ALBUMEN PROCESS,

As tending to show that the Structural Condition of the Albumen plays an important part in the Sensitiveness of the Plate.

By Dr. John Ryley.

[Read before the London Photographic Society, on Tuesday, December 4th, 1860.]

While making some experiments, in the spring of 1858, with a view of obtaining a dry collodion plate that would be more sensitive and uniform in its action, I was surprised to find the great difference between the sensitiveness of plates prepared with honey, gelatine, and gum, as compared with those prepared with albumen; for, while the three former are nearly alike in sensitiveness, the latter will not give results to them under six or seven times the exposure, and the greater the care bestowed in washing away all free nitrate before the albumen is applied, the more unsensitive the plate becomes; so that, contrary to all preconceived opinions, albumen (in my hands at least) has become a retarder, and not an accelerator, of the collodion film.

This effect I believed to be due to an altered structure of the albumen more than to chemical action. Coming to this conclusion, the thought struck me that if the plate, after being allowed to dry, was again immersed in the nitrate bath to coagulate the albumen, I should restore its sensitiveness; and so perfect was my success, that I took with a half-plate lens a negative portrait in thirty seconds, also one with a quarter-plate lens in fifteen seconds.

Having arrived at this point, another thought came across my mind, which was, that I might do away with the re-dip in the nitrate bath by using cadmium-collodion, as the free nitrate of that metal left in the film would be sufficient to coagulate the albumen. This I tried, and so far succeeded that I took a portrait of my son in about six seconds with a quarter-plate lens.

Being anxious to test my theory to the utmost, I determined to alter the structure of the albumen by the most simple means. Therefore, after taking my plate from the nitrate bath and washing away all free nitrate, and coating it with albumen, I plunged it into a bath of hot water (just below the boiling-point) for a few seconds; and so sensitive was the plate treated in this way, that I took a good negative with a stereoscopic-view lens and pen stop in less than thirty seconds. In conclusion, let me state that very good results may be obtained in the following way:—After washing the plate from all free nitrate and coating it with albumen, I wash off, as proposed by Mr. Fothergill, and then wash with a two-grain solution of gallic acid to alter the structure of the albumen; or you may use tannic acid instead, which is more sensitive, but more liable to solarise.

"GREAT EXPECTATIONS."

We have felt it impossible to resist a strong temptation to use the above title as a peg to hang a photographic chapter upon. This temptation is afforded by the fact that the great novelist has not been able—or at least has not thought fit—to get through the first column of his charmingly *naive* tale without alluding to photographers. We owe him thanks for that, though readers of this Journal would not need to have it so strongly introduced to their notice; for what is the whole narrative, as far as it has yet gone, but a photograph of the most positive description? The author has wonderfully developed the observations of the mental camera; and his images require but little fixing in our remembrance, for they are "familiar in our mouths as housenold words."

We say, what are the pictures of the villain convict, hardened in crime—the youthful Pip, brought up by hand, without so much as a sense of moral responsibility to prevent his following the commands of his terrible acquaintance—of the connubial pair so strangely mated, and leading such independent, yet dependent, lives—of the parish clerk who wants the church throwing open—of Uncle Pumblechook—what is all this but a stereograph, so to speak, of the best quality, to say nothing of the scenery,—the busy forge, the neglected churchyard, the distant dismal marshes, with the stakes keeping the tide out, visible with the gibbet against the horizon, the well-stocked pantry, and the characteristic Christmas dinner?

We have "great expectations" indeed of more positives by the same author. But his reference to photography carries us back to the pre-photographic period—the age before iodine became acquainted with silver; when short cotton crops affected the Liverpool brokers, but not the portraitist as yet ignorant of collodion; when lens-makers thought of achromatism it is true, but wot little of actinism; when there was no photographic past for Mr. Griffiths to croak at. (From his name we should have imagined a more sanguine man with "*great expectations*" of the future.) This was the ante-railroad epoch, when also the phosphorous bottle yielded both light and fire like its brother the tinder box, which was not yet honoured with a place in the Ashmolean Museum, where one may now be seen, with other marvels of the nineteenth century; when the policeman's bull's-eye had not yet superseded the lanthorn of Dogberry, soon to "pale its ineffectual fire" before the brilliant gas of the present day. But there was even then a dawn of "great expectations." Bichromate of potash and some other things had already shown symptoms of usefulness, though light, latent and bottled, had not yet even visited our dreams.

We are, however, forgetting Mr. Griffiths (would we could do so altogether); but we think, with Mr. Hardwich, that such disencouraging arguments as he offers should be condemned. It is perhaps scarce worth our while recurring to this subject, but the Chorlton Society seem inclined to keep it before us. Looking at this question, as a bystander on a passing game, it strikes us we get a good view of the whole matter. There is more implied in the title of Mr. Griffiths's paper than he is able to maintain. He professes to deplore our present ignorance, but does nothing to dispel the darkness which he seems to feel himself. What does he mean by saying that "even now, though ten years have elapsed since Mr. Archer's discovery, its effects are becoming known?" Does he want them to stop? If words mean anything, it is that its effects are beginning to be known, which it would puzzle a first wrangler to prove, and which we utterly deny. Perhaps he means its effects are becoming increasingly known, which is just what every lover of the art has most at heart.

Again, he says portraiture was the first practical use of photography. Perhaps so (do not let us forget the origin of portraiture represented by the Infant Cupid limning the shadow of his mother on the wall); but when he adds that landscape photography is next in order of usefulness, he of course infers that portraiture is still the *first* advantage of the art—which is very like saying omnibuses are more useful than railways, and cabs than either, because there are more of them. We think the verdict of our readers will be, "not proven."

But we do not want to rewrite Mr. Griffiths's paper, or one paragraph after another might be treated thus. We cannot fancy even Mr. Griffiths saying to any son of his—"it is of no possible utility your pursuing this or that branch of science; you will know no more in ten years hence than now:" and yet that is what his argument amounts to in our opinion.

Philosophers do not even yet know really and positively what electricity is, and see how long they have been at that. There are sceptics yet who think gravitation is not yet settled; and behold!

how fiercely the origin of species is now contested! The philosopher's stone and perpetual motion are impossible things, but some great results have attended their pursuit. And surely a man must not be deterred from the study of mechanics or chemistry because they are, and likely to continue to be, among "things not generally known."

Mr. Wardley thinks if Mr. Griffiths had said nothing about collodion Mr. Hardwich's "Comments" would not have appeared; so neither would Mr. Griffiths's very unwise remarks, for he refers to nothing else. We do not see any ground of complaint against Mr. Hardwich, who has entered upon the discussion with that gentlemanly feeling which is always the character of his "Comments."

Photography has had an immense influence in the world. Young in years, it is a very Infant Hercules in strength. We have shown, and may show further some day, how literature seems to have found a mine of wealth in it; nay, we think it might be shown that dress, fashion, manners, have come under its power. It has opened to us a vast new field of chemical inquiry; it has stimulated and originated a large amount of mechanical skill; it has brought together men of science of all grades; it has created a brotherhood, so to speak, of art and science combined; and not the least of its benefits is the pounds-shillings-and-pence side of the question. But it never would have done this—its place would only have been an aching void—had Mr. Griffiths's arguments obtained at the beginning. There is no fear of their doing so now; and in place of using them himself in future, let us hope that he will be able to realise a few "great expectations" which will not be so gloomy as his retrospect of the past, which seems to be drawn from the "night side" of the question.

ON THE PISTOLGRAPH.

By Thomas Skaife.

[Read at the North London Photographic Association, on Wednesday, Nov. 28, 1860.]

I have been asked, over and over again, why I call a certain little photographic instrument a "pistolgraph?" And over and over again I have replied by saying:—Because the little instrument, when first invented, was in size and shape not unlike a pistol—was held in the hand, and manipulated by means of a trigger, like a pistol: one being constructed to take life, the other likenesses.

The pistol camera, constructed to take pictures on concave glasses, was first introduced to the public about two years ago; but, on being modified to take pictures on flat glasses, it took the name of pistolgraph—the termination "camera" being exchanged for "graph."

Camera, though very euphonious in photography, is at best but a *pis aller*, as the French would say. Camera, in the original Italian, signifies a room, parlour, or bedchamber. A photographic camera is understood as the instrument by which photographs are taken.

But with more propriety, from a linguist's point of view, this name should be given to the photographer's dark operating-room. In this respect the French are not much in advance of ourselves, for they call their camera a *photographic "chambre noir."*

Telegraphy, in its terms, is much in advance of its sister science, *Photography*. The close relationship between light and electricity suggest a relationship in their several terms. The electric telegraph is the quickest instrument known for the conveyance of messages. The photo-pistolgraph is believed to be the quickest practical instrument known for taking children's portraits. By common consent a telegraphic message is now called a telegram. Why may not, with equal propriety, a picture thus obtained (a light engraving, if you please, in black and white) be called a pistolgram?

Life is short, but art is long. The craving for new ideas is inexhaustible; but eyes will wear out.

Commercially speaking, short, terse words pay better than long, euphonious phrases. In print the latter cost sixpence more—a sordid consideration, truly; but still it has its weight with those who work for bread as well as fame.

STEREOGRAPHS.

Chester and North Wales Illustrated, by Francis Bedford.

(Chester: Catherall and Prichard, Eastgate Row.)

There is, perhaps, no more perfect specimen of a walled city now extant in this country than the ancient city of Chester; and there are few persons who have any pleasure in contemplating the records of a by-gone age but must experience a thrill of pleasure on wandering for the first time surrounded by the numerous tokens which it contains of the former existence of customs and habits long since passed away. The wall, which, in ancient times, was erected for the defence of the city, entirely surrounds it, and is still in a state of very good, if not perfect, preservation. It is about two miles in circumference, and is sufficiently broad to admit of two or three persons walking abreast on the top of it. At the present day its chief use is to form a promenade; and a very pleasant one it is, affording agreeable prospects of the surrounding country, including the famous race-course and the river Dee, on the banks of which it is situated. When we say the wall surrounds the city entirely, we do not mean to assert that there are no extramural dwellings. On the contrary, there are many of them; but these are chiefly of modern date, the oldest of them bearing no comparison in age to those within the walls, though perhaps none of the edifices now standing were so as far back as the time at which we have records of the existence of the city itself, which date as early as A.D. 607.

The most striking features of all to a stranger are, however, the "rows," or terraces, evidently designed with a view to affording additional shop accommodation in a contracted space, necessarily limited when the walls served their original purpose of defence. In the streets where these rows are found the front rooms of the storeys immediately above the ground floors of the houses are absent, the back rooms being, as a rule, converted into shops, and the third stories project overhead as far as the basement storeys; so that a sort of covered terrace pathway is formed over the tops of the shops which stand in the ordinary level of the streets. To these terraces access is obtained by means of flights of steps at irregular intervals from the main thoroughfares; and, as the houses were originally built in the most independent fashion—scarcely any two contiguous ones being of the same height or style as regards any of the several storeys—the effect produced is highly picturesque, if not convenient. But for the narrowness of the streets, Chester would be a photographer's paradise in affording subjects. As it is, however, there is rather too much of the cup of Tantalus as an unavoidable ingredient to allow of unmixed gratification.

Amongst the series now before us, No. 61, Bishop Lloyd's House in Watergate Street, gives an excellent idea of the appearance presented by some of the more ancient edifices which we have been endeavouring to describe, and in which slide one of the flights of steps leading to the rows is discernible, as also the variation in the level of the adjoining houses. The quaint old carving on the wood-work forming the entablature, and on the front of the topmost storey, under the high-pitched gables, is of itself a complete study, and would, for this feature alone, render this slide valuable.

No. 38, Eastgate Street, containing a view of the publishers' establishment, illustrates the method in which the characteristic arrangement of the rows has been retained, even with the modern erections, which are almost exclusively to be seen now in this street.

No. 45, Watergate Row (South), must have been a very trying subject for the camera, in consequence of the marked absence of light—indeed, more trying than many interiors. Here the spectator is located on the footway of the row itself, and looking along it. The ups and downs of the pavement are readily perceived, arising from the varying heights of the shops below; and the low ceiling formed by the floors above recal vividly to the memory the strange impressions produced on first beholding the place itself.

Amongst the illustrations of North Wales, some Cottages at Aberglaslyn, Beddgelert, No. 188, form the subject of one of the most excellent slides of the series. With low thatched roofs, and windows "pitched" in anywhere, built in a hollow at the base of a towering hill of slate rock, and backed by a clump of trees, which are seen through a partial veil of transparent smoke issuing from the cottage chimneys, while the road winds in a graceful curve towards the left hand, fenced off by low walls of loose stones, these cottages, which are ostensibly the subject of the picture, really form but an insignificant element therein. In the foreground, a fine fir tree stands out boldly; and on the extreme right the windings of the valley, backed by many distant hills, are rendered with a truth of atmospheric effect that is highly to be esteemed. This is in our estimation one of the gems of the series, whether as regards composition (if we may apply this term to happiness of selection) or execution. It is in every way satisfactory.

Stone Depot at Penmaenmawr does not sound very attractive as a title; but the slide, to which it is applied is an exceedingly good one as a photograph, and by no means unpicturesque. The gentle curve of the bay on the left, repeated by that of the railway

just clear of the beach, together contrast admirably with the rugged outlines of the rocky mountains in the far and middle distance; while on the right hand is a precipitous slope, down which huge masses of stone from the depôt above have rolled in admired disorder, while numerous cottages seem to be disposed in various parts of the view *much upon the same plan.*

For breadth of effect, No. 118, LLANBERIS PASS, *from Pont-y-Cromlech,* can scarcely be surpassed. As a study of light and shade, it is truly magnificent. The somewhat insignificant stream in the centre, which reflects an intensely white glare from the unveiled sky, *stumbles,* as it were, amongst the huge boulders which have rolled from the massive ranges of rocky hills on either hand, which form the far-stretching valley:—those on the right o'ershadowed by a frown; while the distant parts of the opposite range smile with a reflected gleam of sunshine, melting into shadow with the most delicate gradation of half-tone, as the eye is turned towards the nearer portions of the valley. In this slide there is next to nothing of "incident." The whole value consists in the *chiaroscuro;* but then what a value it is!

No. 150, BETTWS-Y-COED, *Pont-y-Pair,* from below Bridge, is about as complete a contrast to the preceding as could well be conceived. In this, hill and rock and the very stream itself are almost smothered in a wealth of verdure. In that, all is stern severity—perfect in its very sterness, it is true: in this, there is a lavish indulgence in graceful foliage. In the foreground a huge mass of rugged and grotesquely-formed rock juts, promontory-wise, out into the stream, and upon which, in a naturally-formed hollow, sits a youth. In the middle, the stream, dashing from side to side in a zig-zag direction, courses along in the deeply-worn rock channel, and across which a bridge is thrown; but so densely is this bridge covered with the luxuriant ivy, that little more than its outline is suggested, not seen, while behind it the graceful feathery tops of a clump of fir trees are themselves backed by high hills, with fir-crowned summits and wooded base. On either side the stream numerous forest trees revel in wild luxuriance—the ash, sycamore, and holly being plainly discernible. Beautiful as this slide is, the effect is a little marred by a trifle of over-development of the negative. The same observation applies also to one or two others; and, though it may savour of hyper-criticism to point it out, we have no fear of being misunderstood by the clever artist who produced these charming pictures, whose aim is always to advance still further towards perfection. Mr. Bedford's larger works are too well known to need commendation from us. We have on many occasions before the present expressed our deep admiration of his style—artistic, neat, compact, clear, and brilliant; but it is in all probability the latter quality—excellent in larger single pictures—that, in a trifling degree, takes from the effect of a few of his stereographs: for it may be regarded as a very general rule that even dull and heavy-looking stereographs, when viewed in the instrument for which they are designed, not unfrequently surpass in beauty the more brilliant and striking specimens when viewed without its aid. And the reason why this is so is not difficult to discover on consideration of the subject; because the single eye, which of itself does not readily appreciate distance, requires the aid of high lights and deep shadows in an *exaggerated degree* in order to arrest the attention at particular prominent features in the subject. But when both eyes of the spectator are employed to view a single picture, the fact of its being delineated upon a plane surface becomes unmistakeably evident, and the artistic exaggeration of the high lights becomes doubly a necessity in order to give effect to the subject; but when each eye has presented to it its own proper picture, then there is no need to indicate by extraneous artifice the prominent features. It is for this reason that we constantly recommend the use of an iron developer for stereographic negatives; because there is less danger of exaggerating the effects of light and shade: a softer negative is generally produced than when an organic developer is employed, more especially when the exposure has been a trifle too short; and this does not preclude the possibility of after-intensification with pyrogallic acid, if found desirable.

No person who is making a collection from this series should omit including A GROUP OF WELSH PEASANTS, eminently characteristic as it is of the costume and general appearance of the poorer class of Welsh women. An old woman is seated in a chair at the cottage door, knitting; a younger one is just starting on some errand, with milk-can on her left arm, and poising a huge brown pitcher on her head; while another, dressed in the broad-brimmed beaver hat and singularly ugly full-frilled muslin cap, with boat-shaped market-basket on her arm, appears to be conversing with her. The middle figure of the group is evidently constrained; but the other two are posed easily and naturally, and the verity of the nationality is unquestionable.

We have marked many more of this admirable series for comment; but we have already extended the present notice to so great a length that we must defer till a future time further mention of them. We propose, however, returning to them in due course.

NOTES OF A PHOTOGRAPHIC YACHT VOYAGE IN THE MEDITERRANEAN.

By W. J. C. MOENS.

(*Continued from page* 351.)

WE sailed for Malaga on the 14th November, arrived at seven the next morning, and immediately made preparations to go up to Grenada in order to pay a visit to the Alhambra. We got leave to pass our photographic apparatus through the Custom-house, which we did in the morning, and left our portmanteaus on board till it was time for the diligence to start; but, to our great disgust, when we landed in the evening we found it was too late for the Douane. We made a frightful disturbance, but it was of no avail; so we returned on board, tied up some few necessaries in a pocket handkerchief, and, putting a box with a dozen 9 by 7 glasses (which are highly contraband) in my pocket, landed again, leaving our portmanteaus to come up the next day. We started at nine in an old-fashioned diligence drawn by twelve mules, two and two, with a number of bells on the collars of each, the jingle of which during the whole journey was deafening. At half-past one Malaga was still in sight, we having been ascending slowly, but steadily, for four hours and a half. We arrived at Grenada at half-past two on the 17th, after a most lovely ride through magnificent mountain scenery.

As soon as possible we presented a letter of introduction that Mr. Mark, our Consul at Malaga, had kindly given us to Mr. Contreras, who is engaged in restoring the Alhambra. He gave us the use of one of his rooms, and got us permission from the Governor to do what we liked in the picture way. We feasted our eyes on the glories of the ancient possessors of Grenada, and then returned to a less etherial but equally satisfactory repast at the Victoria Hotel. The next morning we got a guide and packed our *impedimenta* on a mule, with whose owner we had a most violent altercation in the street, opposite to the hotel, with a crowd of spectators round us, as to the possibility of putting our things the right way on the mule's back; he always persisting in slinging everything upside down, particularly my friend's nitrate bath, which was in a case by itself. At last it was packed all right, and everything was landed in safety in the Alhambra, which is on the top of a hill, with the river Darro running at its base. After having another look at the beauties of the place, we ascended and took a panoramic view from the top of the tower of the Vela. It was so late in the afternoon before we began to photograph that the third picture of the series proved a failure from the rapid diminution of light, which here takes place much more rapidly than in our northern climes. We spent a week at this charming place, taking several views, both interiors and landscapes, the exposure varying from twenty seconds with my large, to ten minutes with my stereoscopic, lenses. One cloudy morning bothered me frightfully: I spoilt two plates before getting a satisfactory picture. The light was so very actinic, I could not account for it in any way.

We made friends with some compatriots here. The ladies of the party were sketching and painting; and they greatly envied us our facility of knocking off pictures in as many minutes as it took them hours, particularly that of the Court of Lions—the perspective of the columns and fretwork of the courts driving them to distraction.

We returned to Malaga in the *corrieo,* or light mail cart, and on arriving at midnight were deposited at the post-office, with all our luggage, which the officials would neither take to the harbour (except at an exorbitant charge) or allow to be left in the office. About twenty ruffians were yelling at us in an unintelligible lingo: the only thing we could make out being that whatever we wished done was impossible. So we thought the best thing under the circumstances was to sit down on our luggage and go to sleep, for we were very tired after a long ride of seventy miles. This staggered them; and after a few minutes an official came out of the interior office, and told us that we could leave them till the morning, which was all we wanted. The next day I tried a view of Malaga, but found that the shaking during the journey had deranged my bath—pin-holes and small spots appearing all over the plate. I was using Ponting's collodion, which seems to make the bath very acid after using it for some time, but a little acetate of soda always brought it right again. At Malaga we met Mr. M——, a brother photographer: he was stopping there, for the benefit of his health, during the winter months. He had been using some of Hill Norris's dry plates: some had turned out very well, but he found them rather uncertain. He was much pleased with the new (to him) method of printing with alkaline chloride of gold.

On the evening of the 25th November we sailed for Algiers, which we reached on the 29th, after a long passage on account of the light winds. The town is situated on the east side of Cape Caxine, on a hill so steep that from nearly every house the sea can be viewed. The houses are all white-washed outside, so that from a little distance the town looks like a chalk cliff: the streets in the Moorish part are very narrow, but the French have

built a wide street and a very fine square. On landing, a strange scene presented itself to our European eyes—Negroes, Moors, Arabs, and all those indescribable beings you only see in an Eastern city, wearing garments of every colour and cut. The native women looked more like ghosts than anything else, being clothed entirely in white; their faces covered, and wearing large loose trousers in lieu of petticoats. We called on our consul, Mr. Bell, who lives in a street six feet wide, in a very nice Moorish house, which, though only bare whitewashed walls outside, within is a little alhambra, with fountain in the centre court, all the arches of the horse-shoe shape peculiar to the Moors, and the ceilings of the splendid lace work they are so famous for. On the 7th December, the day before leaving Algiers, we got permission from the authorities to photograph, which is quite necessary to obtain in a foreign country; for without it you are sure to get into trouble, and run the risk of getting your apparatus damaged by some little petty official. We took a panoramic view of the town and pier from the battery at its extremity. On the pier are a number of blocks of concrete, about 10 feet square, which are built up, and, when hardened, are upset into the sea to strengthen the breakwater. The exposure here was very short, about seven seconds for our 9 × 7 pictures, and almost instantaneous for stereoscopics.

On the morning of the 10th of December we entered the bay of Boujeiah, which is situated between Cape Carbon on the west and Cape Cavalo on the east. This bay is one of the safest in Algeria, being only open to about three points, and will prove a most important naval station to the French in the event of a war with this country.

Boujeiah was the prettiest town we saw in Algeria—Beni Tchondju (4730 feet high) and Babor (7087 feet high), rising close behind it. On one of these is an ancient Saracenic castle: the highest peaks of the North Atlas range stretch away eastward. The rocks of Cape Carbon are magnificent, rising perpendicularly from the water, of a deep red colour, from the quantity of iron ore contained in them. Boujeiah was founded by the Carthagenians under the name of Saldœ: a number of ruins a little way from the town show the site of the ancient city. The old walls still exist: part of them, between the Castle Abd-el-Kader and the Saracenic Gate, were overthrown by an earthquake in 1857. The town is still supplied with water by the ancient aqueduct. We landed early in the morning with the photographic apparatus, the Douane authorities having told us that we might do what we liked: so we sent up our cards to the Commandant, who had gone out shooting, and commenced taking pictures—two gendarmes, in rather an excited state, watching us in order to prevent our taking the fortifications. My friend went up to see the mayor, who wanted to know what we were doing.

I had just finished when two officers and some soldiers came up, ordered us to rub out all our pictures, and told us that we, with our men who were helping us, and our apparatus, were all to go up to the bureau of the Commandant. Here we found the second in command in a very savage state, insisting on all the pictures being rubbed out immediately; and that we were not to be allowed to go on board till the Commandant returned, which might be in a day or two. We remonstrated, and refused to destroy the pictures till his superior had seen them, and got leave for the two sailors we had with us to go on board; but we had to remain. So we amused ourselves by taking a walk, and looking for the fortifications that they seemed so jealous about. Besides the old castles that had guns on them, we found several new earthwork batteries, to mount heavy guns, thrown up a little to the north of Fort Abd-el-Kader, having a complete command of the bay. This struck us as being very significant of the intentions of the French Emperor; for the English is the only power likely to be of any danger to him on his sea-board, particularly on the coast of Algeria. We continued our walk to the lighthouse, and on returning were met by an officer who told us that the Commandant had come back, and that we were at liberty to do what we liked; so we revisited the bureau and found our former persecutors turned into friends. They gave us oranges and brandy and water, and went on board the yacht with us; and now they wished to detain us as visitors, offering to get up hunting parties, lend us horses, and do what *we* wanted. But our dignity had been touched, so at four o'clock we set sail for Cagliari, and when we turned in for the night were doing ten knots. I forgot to mention the great variation of actinism at Boujeiah—in a quarter of an hour the exposure altering from twenty seconds to two minutes, and this in cloudy weather.

(To be continued.)

HOW TO VARNISH THE NEGATIVE.

By R. W. Thomas.

[Read at a Meeting of the London Photographic Society, December 4, 1860.]

This subject is deserving of careful attention, at the same time all that can or need be said concerning it may be stated very plainly and in a few words.

I will endeavour to explain and comment upon the two methods now in use, and will distinguish them by the terms "hot" and "cold." I apply the first term hot to the process making the warming of the plate necessary, previous to pouring on the varnish, which is applied whilst the plate is still warm. This method is very generally followed, notwithstanding the inconvenience of heating the plate; for the reason, that the coating left upon the surface is perhaps harder than when cold varnish is applied, and consequently stands a greater amount of rough treatment—no doubt a desideratum. Ordinary spirit varnish, whether French or English, contains a certain amount of water; that is to say, the spirit generally used is not absolute. A more fluid, and consequently a better, varnish can, I think, be made with absolute alcohol — at least, such is the result of my experiments; but, whatever strength of spirit is used, the effect of all spirit varnishes, more or less, is to interpose between the image on the surface of the negative and the prepared surface of the paper a layer of gum more or less thick. I need hardly say that any intermediate film must prevent absolute contact of these surfaces, and consequently detract somewhat from the sharpness of the picture.

There can be no very great mystery as to the composition of spirit varnishes when it is considered that the gums we have to select from are not numerous; viz., copal, animi, sandarac, thus mastic, lac, and dammar: these gum resins have however various properties, some being harder and more vitreous than the others, whilst some are sticky and resinous. It is therefore very desirable to make use of both these qualities by selecting and combining judiciously such of the gums just enumerated as shall give a varnish possessing hardness and durability, with sufficient elasticity. The hardest gum cannot be used alone, but must be mixed with one more resinous, in order to provide against the possibility of cracking or splitting up of the surface left on the plate. I find that a mixture of the three first on my list answers the conditions just laid down, if absolute alcohol with a small per centage of chloroform is used for the solvent. This varnish has proved, in my hands, the best of the spirit varnishes. I have heard it remarked that this, and no doubt other strong spirit varnishes, occasionally have a very unhappy property of removing the image from the negative; I must say, that I have never been able to produce this undesirable result myself, and I think perhaps that such an action may have been due either to moisture in the film, unequal application of heat to the plate, imperfect washing out of the hyposulphite of soda or cyanide, or to some peculiar rottenness or condition of the film of collodion. The advantage and disadvantages in the use of spirit varnish may be briefly stated: in its favour, a greater hardness of coating; against it, the inconvenience of having to heat the plate, and loss of sharpness in the positive from the interposed film of gums left upon the surface of the negative. Having disposed of what I have termed the hot process, it only remains to draw attention to that designated "cold." It is not my intention to enumerate the various solvents and gums which are or might be used for the manufacture of cold varnishes. I have tried many of them, and find that all are, more or less, tacky when dry.

I shall confine myself to a few words descriptive of the best cold varnish, which, unquestionably, is that made by dissolving amber in chloroform. Many will be surprised to hear that such a thing as a package of fine amber seldom if ever finds its way to this country; but plenty of a very inferior and rough description is to be met with. The finest kind is used for making the mouthpieces of pipes, which are, I am given to understand, of foreign manufacture. Having learnt this much, I set to work to obtain, through my drug merchants, some further information on the subject, and was fortunate enough to find out the holder of a large quantity of the chippings from the fine pieces of amber, which he had been provident enough to store away. This is not a coarse powder of amber, but unmistakeable chippings, cut as with a sharp instrument, bright and clear in quality, in every respect equal for making varnish to the fine and most costly pieces, of which, indeed, these chippings are a portion. With such a sample as this there is no difficulty in producing a varnish in every respect desirable for photographic use, and sufficiently hard to withstand any friction the surface of a negative is likely to meet with. The coating left upon the negative is perfect, and can be hardly distinguished from the patent plate: this varnish penetrates the film, and adds very much to the beauty and clearness of the negative, at the same time leaving upon the film the thinnest possible coating, thus admitting of the most perfect contact with the excited paper.

I have had opportunities of examining some hundreds of negatives, produced by various operators, both amateur and professional, many of which were more or less disfigured, if not damaged, by the varnishing operation. My method of using the amber varnish is as follows:—I invariably make use of a little distilled water, with which I wash finally the finished negative; this removes the salts of lime that exist, more or less, with other impurities, in all waters, in quantities quite sufficient to prevent the formation of a brilliant surface. (I consider this simple, but cleanly, operation one of the important photographic "insect cares.") Now set the negative up to drain and dry spontaneously, face to the wall, and its lower part resting upon a slip of clean bibulous paper. It is as well to change this slip of paper once or twice. When surface dry, the negatives may be put into a grooved box to keep them from dust; and, if more convenient, they may be varnished next day. All varnishes should be applied in a dry room.* Attach the back of the negative to a pneumatic holder kept for the purpose, and having poured into a glass measure more of the varnish than is required to cover the plate, proceed to pour on as much as the plate will hold; keep the plate as horizontal as possible, and let the varnish soak well in for twenty or thirty seconds; then gently raise the plate and pour back

* Just before varnishing, pass the back of the plate over the flame of a lamp, to drive off any moisture: allow the plate to cool before pouring on the varnish.

into the measure the excess from the nearest right-hand corner. The varnish must not be dashed off, but the plate very gently elevated, at first only just out of the horizontal, and very gradually raised until it stands vertically on the edge of the measure; in this position let it remain a few seconds; on no account rock or give it any eccentric motion, and during the whole operation hold the breath, or turn the head away from the plate to breathe.

Always have two bottles for varnishing, the one to contain the stock of bright filtered varnish; the other to receive the portion poured back into the measure from the plate: when sufficient has been collected in this bottle, filter it through paper into the bright stock bottle. Amber varnish filters most rapidly and with a very slight loss. The measure used should not be washed out, but kept turned down and free from dust; it is then always ready for the purpose required.

I possess a negative portrait of Sir John Herschel, taken about six years ago, that I value very much. This plate was varnished with some varnish made of very fine amber: it does not show the slightest sign of decay—is indeed harder than when first varnished. I have also negatives kept under various circumstances of damp and heat for eight years, and still perfect. I am not alone in expressing a strong opinion in favour of amber varnish: both my own experience and that of many photographers enable me to recommend it in preference to any other; and I think the thanks of photographers are due to Dr. Diamond, who I believe some years ago first introduced it to notice,

Letters to a Photographic Friend.

No. X.

MY DEAR FRANK,

I NOW resume the record of my last day's photographic "experiences" in the Modern Babylon, which I was obliged to break off abruptly in my last letter.

From M. Bourquin's away I posted to Horne and Thornthwaite's, to overhaul a piece of apparatus that, though not an ordinary article of trade, Mr. Ackland kindly gave me the opportunity of examining in their portrait operating-room, and likewise favoured me with photographs of the apparatus figured below. This instrument is arranged for adjusting pictures, prints, &c., that have to be copied by photographic agency, to the propor position on the plate, or to the focus of orthographic lenses, &c. In *fig.* 1 we have a representation of the front view of the instrument. You will perceive that it consists of a series of sliding-frames, so as to permit the picture, &c., being adjusted to the desired heights, the horizontal adjustment being effected by pushing the apparatus in a lateral direction. By consulting *fig.* 1 you will see that a handle is fixed on a central pinion, which acts on a mill-head, shown in *fig.* 2: on rotating this, the frame carrying the picture, &c., works upwards or downwards. By shifting the key-handle to the pinion to the left hand in *fig.* 1, it acts on the mill-head attached to the right hand rod in *fig.* 2, and this brings into play an adjustment that allows of the picture being inclined towards the camera, which you will better understand by consulting *fig.* 3. By rotating the right hand rod in *fig.* 2 the screw in its upper part acts upon a piece of frame-work, A, so that it is forced upwards. As an inner frame, B, is hinged to this, and is also hinged to C, a frame that carries the picture clamps, and which is hinged at the point D, *fig.* 1, is forced forward, and with it the picture carried by this frame. Thus an upward or downward, a forward or backward, or a lateral motion, is placed at the disposal of the operator. As this is an eminently useful piece of apparatus in these "copying" days, I have thought it advisable to draw your attention to it, for I see no reason why this should not be a marketable article.

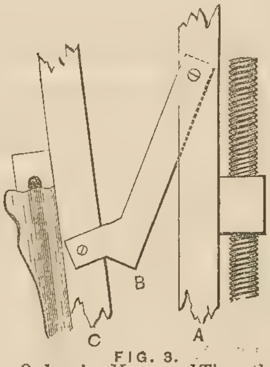

FIG. 3.

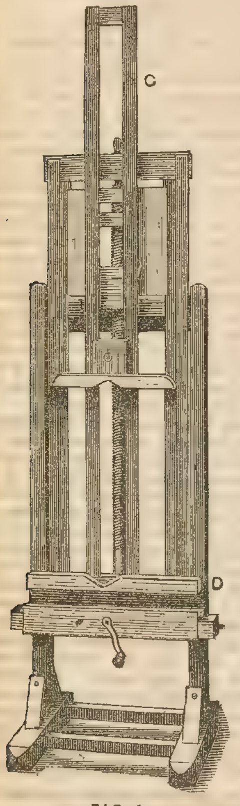

FIG. 1

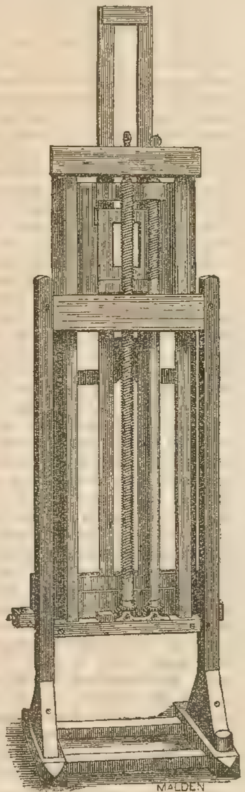

FIG. 2.

On leaving Horne and Thornthwaite's I made my way to Meagher's, in Coppice Row, Clerkenwell; and here I had an opportunity of examining the form of camera that I reported to you in my last as "shaky." Having had his attention drawn to the weak point of the arrangement, Mr. Meagher has so modified the construction that his camera is now as rigid as any of the same type that I described to you as adopted by several makers;—at the same time combining with this form a swing-back motion. The dimensions of the camera examined were 13½ by 11½, and three inches thick when packed, and when extended gave a range of 22 inches for focussing. I also had brought under my notice a twin lens camera, *fig.* 4, with "the iron roller-like shutter" of arrangement I have previously described, combined with the plan of fitting the focussing-glass so that it recedes behind the plate frame; thus the ground glass need never be removed from the camera. As, however, the glass is exposed when travelling, it is in this case guarded by a flap-door, hinged at the back of the camera. When one wishes to focus, this flap is lifted up, two side pieces attached to this door turn down, and thus a dark screen is formed to shade the ground glass during the operation of focussing; this is indicated in the back part of the drawing. Mr. Meagher states that both the roller blind and the receding focussing-glass came under his notice, about two years ago, in an American camera he had to repair. So, indeed, "there is nothing new under the sun."

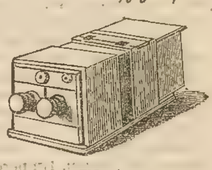

FIG. 4.

I have now to answer a few queries that you put to me respecting colours and artists' materials; but, as I have no experience in the practical details of photographic colouring, I have met your wishes by consulting our very good friend, Mr Wall. First, you ask me—What are the best colours for tinting glass positives?—and he tells me, from his own experience, those of Newman, Mansion, and Reeves. For oil and water-colour, Newman.—Next you ask, Where can I obtain the best brushes?—and our friend says at Clifford's, Piccadilly; Barbes', Regent Street; Newman's, Soho Square; and Miller's, Long Acre. But there *are* others of whom report speaks well:—Miller's "Silica Medium" our friend thinks "the best out," for oil, being colourless, and *remaining so*, to a much greater extent than any other in the market, and it also enables the colourist to use his pigments in a more transparent condition, without the excess of medium acting injuriously upon the colours, or destroying their purity.

And now, my dear Frank, in bringing to a close my engagement with you (to tell you of all that came under my notice in the London photographic market, and give you my candid opinion on

all I saw), I have endeavoured to the best of my judgment to do justice to all things and persons, and that in a way totally unbiassed by any motives that can in any way be called interested, or notions that can be classed among the preconceived. As my review was voluntary and unsolicited, I have not, in my letters to you, noticed those things put before the public that for one reason or another I have not thought worthy of their attention; but I may say that I have met with inventions, good *in principle*, but carried out in such an ultra economical manner, that they have counteracted the good *idea* by the inferiority of their workmanship. And here I would protest against the fatal economy of those who seek after things TOO CHEAP; for it should never be forgotten that "every labourer is worthy of his hire," and that the *very* cheap article is not always *cheap in the long run.*

I must now conclude these communications, for in a few hours I shall be whirling back to my native home; and ere many weeks are passed I shall be closed in by piled-up snow-heaps that will shut out the noise and din of the far-off but ever busy London. So adieu till we meet again; and believe me,

Dear Frank,

Yours sincerely,

SIMEON HEADSMAN.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

THE second monthly meeting of this Society for the season was held on Tuesday evening, the 4th inst., at King's College,—Peter Le Neve Foster, Esq., V.P., in the chair.

The minutes of the last meeting having been read,

Mr. WATSON objected to them on the ground that they stated that Mr. Rothwell's paper had been read at the last meeting, whereas the fact was that only the merest fragment was read on that occasion, so that those members who had not had an opportunity of seeing the paper beforehand could not understand the subject. The paper could not be said, under these circumstances, to have been properly "discussed," and he thought it would be as well if the paper were again brought before the Society.

The CHAIRMAN said he was sorry to say that Mr. Watson was irregular, and could not be heard upon the subject. If there were any objection to the course of proceeding it must be taken before the council. The statement in the minutes was that "portions" of Mr. Rothwell's paper were read.

The minutes were then confirmed.

The following gentlemen were balloted for, and declared duly elected members of the Society:—E. L. Lloyd, Esq., W. Rowles, Esq., G. Wharton Simpson, Esq., and William Gray, Esq.

The CHAIRMAN said at this meeting they had to act under the 7th rule of their Society relating to the election of their officers. The following were the names of the gentlemen retiring by rotation:—Messrs. Roger Fenton, V.P., T. F. Hardwich, Henry Pollock, F. H. Wenham, Mackinlay, and Marshall.

Professor Bell was recommended for election as Vice-President, making another vacancy in the council.

The Earl of Caithness, Messrs. Roger Fenton, Walter Hawkins, Warren de la Rue, T. R. Williams, and Rev. J. B. Major, were recommended for election.

Mr. ROBINSON exhibited his large photograph from the life, called *The Holiday in the Woods.*

Mr. ZETZLER, of Sydney, New South Wales, exhibited a series of stereoscopic views of that country.

Dr. RYLEY then read a paper *On the Result of a Series of Experiments on the Collodio-Albumen Process*, &c. [see page 367], and exhibited illustrative specimens.

The CHAIRMAN stated that some of the plates were prepared six months before they were exposed.

Dr. RYLEY said that during the course of the experiments it struck him that the success he had met with might be owing to the coagulation of the albumen allowing the developer to penetrate the film more freely, and that he might be attributing to the sensitiveness of the plate that which was due merely to the more favourable action of the developing solution. He accordingly proceeded to perform the following experiment:—He took the plate out of the nitrate bath, thoroughly washed it from every trace of free nitrate, coated it with albumen, and allowed it to dry without artificial heat, and then exposed. Before developing he redipped it in the nitrate bath, and then tried to develop the picture, but it proved a failure, thus clearly proving that the success in the cases stated in his paper was due to sensitiveness produced by the coagulation. He wished the question, as to whether the result was due to a structural or chemical alteration in the film, to be fully discussed, as he was not sufficiently versed in chemistry to decide the point, although he was rather inclined to believe that the alteration was only structural. When the plate was redipped in the nitrate bath it would only keep three days; when dipped in gallic or tannic acid the plate would keep any length of time as long as it was kept dry. The plates exhibited great sensitiveness when iodised with the metallic iodides. In using the nitrate of cadmium he found, after washing away all free nitrate, enough remained to alter the structure of the albumen; but on developing the plate it was full of blisters, proving that nitrate of cadmium could not be used for that purpose. If that objection could be overcome it would certainly be the best.

Mr. HARDWICH said that he had experimented upon the sensitiveness of plates prepared with gelatine and gum, as compared with those prepared with albumen. He had found the gum first in sensitiveness, the gelatine next, and the albumen last. He considered it was necessary to coagulate the albumen with nitrate of silver by redipping the plate, if it were desired to obtain the maximum of intensity. By intensity he meant what some termed *contrast—id est*, the opacity of the high lights as compared with the shadows. If the albumen were coagulated in any other way it lost a certain portion of its intensity, and a pale negative was the result. The hot water method might answer for a short focus lens and a brilliantly illuminated object; but not for a long focus lens and a badly lighted object. The action of gallic acid he found was to increase the intensity of the albumen negative, but he did not find that it increased its sensitiveness—rather the reverse. Thus, if he exposed the plate with a lens of long focus without sun, he found the picture exhibited more detail in the shadows when no gallic acid was used, but that the intensity was not so great. It would therefore appear that gallic acid increased the intensity and diminished the tendency to solarisation. In another experiment he took one of Taupenôt's plates, and washed one half in salt and water, and the other half in distilled water. On exposing the plate, the development was more rapid on that part washed in distilled water; but eventually he obtained as much detail in the other part washed with the salt water. Thus he found that salt retarded the development but did not affect the sensitiveness. He washed another plate in salt and water, and then in gallic acid, and the result was that the plate was restored to the same state with respect to contrast and intensity as if he had not washed away the nitrate. If the whole of the excess of the nitrate of silver were washed away, the contrast could be restored by the use of a reducing agent. Dr. Ryley regarded the effect he produced as owing to an alteration in the structure; but he (Mr. Hardwich) regarded it as owing to the chemical nature of bodies which tended to reduce the nitrate of silver to the metallic state. The plates prepared by Messrs. Petschler and Mann were not so intense as those prepared by Taupenôt's process, but they might be rendered so by washing off the albumen and dipping them in gallic acid.

Mr. SEBASTIAN DAVIS said he had been experimenting upon the collodio-albumen process for some time past. He prepared plates, and washed away all the free nitrate, and coated them with albumen. He then placed the plates in an atmosphere of dry air at 180 degrees to coagulate the albumen; on exposing the plates he found they possessed little or no sensibility to the action of light. This would appear to contradict the theory, that it was only necessary to coagulate the albumen to produce sensibility. He then dipped some plates in boiling water instead of exposing them to hot air, so as to wash them at the same time. The plates so treated were far more sensitive, but not so sensitive as the Fothergill plates. He concluded that by washing away all nitrate of silver, sensitiveness was lost to a great extent. Having washed away all the free nitrate of silver from one of Messrs. Petschler and Mann's plates, he washed the plate with chloride of ammonium, when he found that it possessed but little sensitiveness in daylight before washing, even when he had exposed it for two or three hours; but after washing it became as sensitive as if it had been redipped in the nitrate bath. Before the plate was washed in water, however, it had a certain amount of sensibility to solar light. By washing a plate first in distilled, and then in common water, the free nitrate of silver was removed; but by washing it first in common water the nitrate of silver was converted into chloride of silver which remained in the film, and might make a difference in the sensibility. It appeared to him, from one or two experiments, that chloride of sodium had a greater power of retarding light than chloride of ammonium.

Dr. RYLEY said his only object in bringing his paper before the Society was to elicit truth. He would rather it could be proved that the results he had obtained were owing to chemical instead of to structural alteration. He must confess, however, that Mr. Hardwich's argument had not entirely convinced him, because the fact still existed, that if he prepared a plate in the usual way, and after washing away every trace of free nitrate he coated it with albumen, and then dipped it for two or three seconds in hot water, the plate so heated became very sensitive indeed. In the course of six or seven seconds with a good light, a most excellent negative would be produced by such a plate, which, he contended, was intense as well as sensitive. Could Mr. Hardwich inform him how it was that the sensitiveness as well as intensity of the plate was increased by the coagulation of the albumen by hot water? Sulphate of iron, acetic acid, and alcohol would produce a similar effect, but not to the same extent.

Mr. HARDWICH said that the hot water might perhaps wash away the soluble chlorides and phosphates from the albumen. That might account for the fact, that the coating of albumen coagulated by dry heat was not so sensitive. In the remarks he had made he had endeavoured to direct the attention of the meeting to the method of producing the most

intense—not the most sensitive—plates. He considered that however carefully the chlorides might be washed away from the film by hot water, the negative, especially in the sky, would not be so intense as if the plate had been redipped in the nitrate bath.

Dr. Ryley said he found that by altering the structure with gallic acid he obtained a more intense negative than he could get by redipping the plate in a nitrate bath.

The thanks of the meeting were then voted to Dr. Ryley for his paper.

The Chairman said he held in his hand an instantaneous photograph taken by Mr. S. Fry, by Taupenôt's process. Mr. Fry would give them a paper on the subject at their next meeting.

Mr. Thomas, before reading his paper, said the subject of varnishing the negative was one of great importance, and had not yet received the attention it deserved. He had been able to gather the opinions of many large collectors, and he was enabled to state that in nearly every instance the cracking of the varnish was not owing to any peculiarity in the varnish or in the film, but to want of care and caution in carrying out certain simple rules. He did not believe in the cracking of any good varnish if the film were properly washed; neither did he believe that cyanide of potassium was more likely to cause the varnish to crack than hyposulphite of soda. The fact was that people did not wash off cyanide of potassium so carefully as they did hyposulphite of soda, although it really required quite as much washing.

Mr. Thomas then proceeded to read a paper on *How to Varnish the Negative*. [See page 370.]

After reading his paper, Mr. Thomas added that wherever cyanide of potassium was used as an agent the negatives were more prone to crack—not because the cyanide of potassium had any action on the film more than the hyposulphite of soda; but that there was a general impression that the cyanide of potassium required very little washing afterwards, or not so much as the hyposulphite of soda would require. He (Mr. T.) was of opinion that cyanide of potassium required quite as much washing as the hyposulphite of soda, and, from the information he had obtained, he thought he should make it clear that wherever hyposulphite of soda had been used the soda had been much better washed than the cyanide of potassium, and generally the negatives had been more prominent, and that no cracking had taken place, except in a few cases under circumstances which only went to prove the rule. Last year, on attempting to apply amber and chloroform varnish, in a room over an outhouse, where there was never a fire, in very damp weather, it was impossible to get a clear varnish. The dampness of the atmosphere prevented the absolute hardening of the surface of the negative. He thought that, just before varnishing, the back of the plate should be brought over the flame of the spirit-lamp, to drive off any moisture which the film might hold. He did not think that any film, put by for a few hours, could be absolutely dry; even the atmosphere contained a certain amount of moisture. That moisture, he had no doubt, was quite sufficient to account, at times, for the cracking of negatives. It was a great mistake also, which many people made, to condemn amber and chloroform varnish on that account. They were very much in the habit of pouring it on and pouring it off immediately, fancying the rapid evaporation of the chloroform would be a great loss; but he did not think it evaporated so quickly as was supposed, and it was as well to allow the chloroform varnish to soak into the film for twenty or thirty seconds, which left a very good body; and if it were thought desirable to repeat the process, it should be done at once. "The varnish must not be dashed off." That was another point; for he was endeavouring to describe the perfection of varnishing, which was to leave on the surface of the negative as fine a coat or surface as the other side of the patent plate itself.

Dr. Diamond said he had first used amber varnishes in 1851, but he had found great difficulty in procuring pure amber. A great part of the amber sold in London consisted of what was called "Highgate resin." Varnishes made from bad amber did not become hard. The advantage of amber was, that it perfectly withstood damp. He differed from Mr. Thomas in thinking that amber varnish would not stand hard work, for he never had occasion to find fault with it in that respect.

Mr. Thomas said amber might be tested by biting it. Fictitious amber crumbled under the teeth—while true amber did not.

Mr. Hardwich said he agreed with Mr. Thomas, that where cold varnishes were used the plate ought to be previously warmed, as the film did not perfectly dry without heat. He found on one occasion that when he used varnish prepared with absolute alcohol the entire image disappeared, the pyroxyline being dissolved by the alcohol. A very small quantity of water, say four or five per cent., mixed with the alcohol, would prevent such an action, and he wished to know whether that quantity of water would injure the varnish. Some collodions would give way under the action of absolute alcohol, especially when the pyroxyline was prepared in very weak acids.

Mr. Thomas said he did not think that such a small quantity of water added to the alcohol would make any material difference. There would be no difficulty in obtaining a solution of the gums in alcohol ·830 in strength.

Mr. Hardwich said alcohol ·808 in strength would not affect the pyroxyline, but ·802 in strength would.

Mr. Thomas said the only objection to adding water to the alcohol was, that it made the varnish somewhat thicker. The more fluid the spirit varnish was the better, because it then interposed between the surface and the negative a very thin coat. If spirit varnish must be used, he should prefer the use of absolute alcohol if it did not injure the image.

Mr. Sebastian Davis said the image in the first negative plates he varnished entirely disappeared. On applying to the dealer about it he was told that it was French spirit varnish, and that if the stopper were left out of the bottle for some time, so that a certain quantity of water might be absorbed from the atmosphere, so as to reduce the strength of the alcohol with which it was made, the evil would be remedied.

Mr. Fry asked whether any one had found Sœhnée varnish crack? He had had two plates, 18 by 15, totally destroyed by the varnish cracking.

Mr. Thomas asked whether that was Sœhnée varnish?

Mr. Fry said it was not. He did not know what varnish it was. He thought that an inquiry ought to be made, when cracking occurred, as to what varnish had been used, and under what circumstances it had been kept, whether in a dry room or otherwise.

Mr. Downes said on one occasion he had employed Thomas's varnish, and it dissolved a large part out of the film. That varnish he thought was prepared with absolute alcohol. He had never found that defect in Sœhnée varnish; but, whether that was owing to its containing a small amount of water he did not know. With respect to the observation made by Mr. Fry, he found that all varnishes would crack if kept in a damp place. The cracks did not form interstices, but appeared to run up between the surface of the plate and the collodion. With reference to Mr. Hardwich's observation, that the film did not dry properly without the application of heat, he found that when the film was dried simply by the ordinary temperature of the atmosphere it could be removed with great ease by wiping the edges with a cloth; whereas when dried by artificial heat, the film adhered closely to the plate, showing that a very considerable amount of water had been driven off by the heating.

Mr. J. Williams said that he had had considerable experience in the manufacture of photographic varnishes. He thought the use of absolute alcohol an error. His own opinion was, that a mixture of absolute alcohol and ordinary spirits of wine of 60 over proof (which would give a gravity of about ·818) was the strength best adapted for the preparation of spirit varnishes. He did not agree with Mr. Thomas as to the use of the gums he had mentioned; but he considered that gum lac should enter into the constitution and form the basis of every spirit varnish. He thought the lac used should be bleached, powdered, and dried before being dissolved. With respect to amber varnish, he thought it important to bear in mind that the chloroform must be quite pure and not the methylated article, which he had found would not answer, but remained tacky. The chloroform should also be perfectly free from alcohol. He did not think there was so much difficulty in procuring *genuine* amber as Mr. Thomas had said, although the amber in commerce might not be quite *so good looking* as the amber from which mouth pieces were made. Some eminent makers of amber varnish were in the habit of using a mixture of chloroform and ether. His own opinion was not in favour of such a plan, and in his hands such a varnish had turned out bad; he, however, believed that it was considered an improvement by some operators—its principal advantage, perhaps, being that a fluid and a weighed ounce of the varnish would occupy about the same bulk, and the purchaser therefore got more for his money than when he had that made with simple chloroform. There was another *cold* varnish in use which ought not to be left out of the discussion. He alluded to the benzole varnish. The basis of this varnish was generally gum dammar, but it was very necessary that the benzole should be quite pure: that met with in commerce generally contained much fatty matter and would not dry, whereas pure benzole dried and left no stain or tackiness behind. When this varnish was made with good materials he knew it to be a good working varnish.

Mr. Fry said that gum dammar dissolved in benzole made a varnish which, if it had not a little inclination to bloom, was as good as any.

Mr. Quin said that when there was no open crack the plate might be heated, when the film would resume its position and would take a new coat of varnish: an open crack, however, was fatal. He had discontinued using amber varnishes, because he found that they would not stand hard work. He found gums became *tacky* when exposed to a hot sun for a long time.

Mr. Bedford wished to know if any member could tell him what was to be done when the cracking first made its appearance. Its progress was very gradual. It showed itself on a small part of the negative first of all, and if it could then be arrested, it would not do much harm; but in the course of a week or two it covered the whole surface.

Mr. Quin said cracking sometimes arose from over-heating the plate when the varnish was being applied. It ought to be just the heat of boiling water. He found the gum dammar stick to the paper when exposed to the sun.

Mr. Bedford said his reason for exposing the varnish to a great heat was to avoid its becoming sticky when warmed by the sun. It did away with that *tackiness* to which some of the spirit varnishes were liable. He thought Mr. Thomas's suggestion of well washing the plate before varnishing deserved the gravest attention.

Mr. Hughes said, amber varnishes were very easy of application, while benzole, or "crystal-varnish," was more difficult to manage. Sœhnée varnish was prepared by a very old firm in France which had a reputation for its varnishes before photography was discovered. In his opinion it was

a most excellent varnish, although some persons said it was too thick, and others that it was too thin. Gum dammar dissolved in benzole certainly possessed many advantages; but he could not recommend it, as it was not hard, was not substantial, and it left the negative in much too unprotected a condition. After twenty, thirty, or fifty copies had been taken it showed signs of wear. The composition of the Sœhnée varnish was not known.

Dr. Diamond said the Sœhnée varnish was made from a formula by the late Dr. Ure. He did not know its composition, although it had been proved by analysis to consist of a combination of several gums.

Mr. Quin said he found lac in it.

Mr. Heath said he had never found Sœhnée varnish crack.

Mr. Bedford stated that on one occasion he had found Sœhnée varnish become *tacky*, and stick to the paper.

Mr. Thomas hoped that they would receive communications on the subject from the country. It was a good plan to remove the film from the edges of the plate, and to allow the varnish to flow over the margin so as to completely encase the film. He did not consider lac to be a hard varnish, as a sharp point would make a trace on it, which could not be done on the French or any other spirit varnish. He wanted to find out whether the cracking was to be attributed to the varnish or not. He thought that if the cyanide or hyposulphite of soda were properly washed off, and the film carefully dried, the varnish would not crack. He also thought the cracking was owing to the difficulty of applying the heat from a spirit lamp equally over a large surface. Last week he visited a number of gentlemen who possessed large collections of negatives for the purpose of inspecting their condition. He found that Mr. Kilburn, who had some thousands of negatives, used amber dissolved in chloroform, with the greatest success, not having had one case of cracking, except from want of care, either in washing or drying. He fixed with hyposulphate of soda, washed the plates freely, and let them dry spontaneously: he always warmed them to drive off the superfluous moisture, and allowed them to cool before varnishing. He then visited Mr. Herbert Watkins, who told him that he used all sorts of varnishes. That gentleman had some thousands of negatives, and always fixed with hyposulphite. He never had a negative crack; but he was always very careful to wash his plates well. He then went to M. Claudet's, and inspected his very large collection. For some years that gentleman used amber and chloroform, until this time last year, when, on inspecting his stock, he found two or three signs of cracking in the form of segments of circles. He became anxious, and jumped to the conclusion that it was owing to the amber varnish: he now used spirit varnish, and only one or two had since shown signs of cracking. He then went to Mr. Melhuish, who worked upon very large plates. He told him that he never had a negative crack—that he used all sorts of varnishes, but gave the preference to amber and chloroform. If any of his negatives cracked, he had been able positively to say that it was owing to some carelessness on his own part in washing or drying the film. He used hyposulphite, and always washed his plates very freely. He found that Mr. Bedford had a large collection, and that he had negatives cracked both with amber and spirit varnishes. He now used amber varnish. One very important point was that M. Claudet fixed with cyanide, washed it off rapidly, dried the plate over a flame, and varnished immediately. Thus, he thought, it was proved that where hyposulphite of soda was used, the plate well washed afterwards, allowed to dry spontaneously, the moisture being driven off by heat, and the plate allowed to cool, neither amber or spirit varnishes would crack; and where cyanide was used, the plate well washed and rapidly dried, both amber and spirit varnishes would crack.

Mr. Williams said Mr. Thomas unjustly condemned cyanide for fixing plates. That article, however, as generally sold, contained carbonate of potash, which might materially influence the action on the film or varnish. Before it was given up, it ought to be seen whether, when pure, it would have so injurious an effect as Mr. Thomas attempted to prove.

Mr. Thomas said he did not wish to condemn cyanide, but people thought that it did not require so much washing as hyposulphite, whereas it required equally as much.

The thanks of the meeting were then voted to Mr. Thomas for his paper.

The Chairman announced that at the next meeting Mr. Fry would read a paper *On Lunar Photography*.

Mr. Hardwich agreed to read a paper, in February, *On Albumenising Paper, and on the Alkaline Gold Toning Process*, for the purpose of introducing a discussion on this very important subject.

The Chairman said that the next meeting would take place on New Year's Day.

The proceedings terminated with the usual vote of thanks to the chairman.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of the members of this Society was held on Wednesday evening, the 28th ult., at Myddleton Hall, Upper Street, Islington,—George Shadbolt, Esq., V.P., in the chair.

The minutes of the last meeting were read and confirmed.

Mr. Ottewill exhibited a new camera for taking instantaneous photographs, which was described at page 318 of the present volume of this Journal.

Mr. Shave exhibited a number of stereographs.

Mr. Moens read a paper, illustrated by numerous well-executed photographs, entitled *Notes of a Photographic Yacht Voyage in the Mediterranean*. [See pages 351 and 369.] The thanks of the meeting were voted to him for it.

Mr. Moens then exhibited photographs illustrative of his paper.

The Chairman said he wished particularly to direct the attention of the members to the dark box (which was also exhibited) used by Mr. Moens in his travels. It was, as they saw, very small and very primitive in appearance.

Mr. Moens said that the box was so constructed that everything necessary could be carried in it; and it was so fitted that at a glance it could be seen whether anything had been forgotten.

A Member asked what chemicals, &c., Mr. Moens took with him?

Mr. Moens said he took one complete set himself, and his friend took another. When they arrived at Carthage they got another complete set from Ross. Their apparatus and chemicals must have cost £250, but the greater part of them was unused.

Mr. Samuel Fry (of Brighton) asked whether Mr. Moens developed with iron or pyrogallic acid?

Mr. Moens said that he employed pyrogallic with acetic and citric acids. He said foreign photographers took nearly all their pictures with albumen plates, and were amazed that he and his friend could do anything with wet collodion. Certainly the heat of the climate, together with the dust and the trouble of carrying the necessary apparatus, made the wet process very inconvenient. He rather prided himself on having taken a glass bath out with him, and having brought it home again unbroken after travelling so far.

The Chairman, referring to an observation made in the narrative, said at first it seemed strange that English photographers should not be allowed to take views of the fortifications at Gibraltar; but of course it would not do to give the necessary permission to English and refuse it to foreign photographers.

Mr. Skaife then read a paper descriptive of his Pistolgraph [see page 368], and exhibited some of his chromo-crystals.

The thanks of the meeting were then voted to Mr. Skaife, who said the reason he called his camera a pistolgraph was because it worked with a trigger, and originally had a handle, and was sighted like a pistol. It was then held in the same manner, but he now held it against his chest. One of those he now produced was originally intended to take magnified photographs of *the flower snake* by means of a Stanhope lens. The motion of the shutters could scarcely be seen when looking at the front; but on looking behind a spark of light could be seen flashing like a diamond. In one instance a gentleman took a picture as he was riding in a carriage.

Mr. Morley asked what lens was used for the instrument?

Mr. Skaife said the lens was expressly prepared for it, and was a double combination.

The Chairman said it was very similar to the portrait combination.

Mr. Skaife said he used a ⅜ diaphragm for taking portraits, and a smaller one for taking landscapes.

The Chairman, referring to the apparatus on the table, exhibited by Mr. Ottewill, for taking instantaneous photographs, said it was much slower in its operation than Mr. Skaife's pistolgraph, opening by a single shutter from the bottom, whereas in Mr. Skaife's arrangement the two shutters opened from the centre.

Mr. Fry asked whether Mr. Skaife had ever tried the effect of a shutter opening from the top downwards, and falling back inside instead of outside. By that means the foreground was exposed longer than the rest of the picture: the shutter was moved by means of a multiplying wheel. By moving the wheel the eighth of an inch, the shutter was opened and shut. He had tried shutters opening every way, and he had found that method the most satisfactory in taking pictures of the sea. He objected to the shutter opening outside, as he thought it must shake the whole concern, especially when pressure was applied to an outside lever.

Mr. Moens asked whether the vibration would not occur after the shutter was closed, when it would not matter?

Mr. Fry said he found the vibration sufficient to spoil the picture.

Mr. Moens asked whether it would not be better to have two shutters —one to fall from the top, and the other to rise from the bottom, so as to meet half-way? He thought that where a long focus was used the shutter was better from the side, especially in sea pictures, where the foreground was as bright as the sky.

Mr. Fry said there were exceptional circumstances in reference to the sea; such as when the sun was opposite the camera, when the dark side of the waves would be towards him, or when the sea was of a green or yellow colour, as it frequently was.

Mr. Morley then exhibited his new mount for lenses.

The Chairman said all the diaphragms were arranged on a plate, as in a microscope. He would recommend that the plate should be fitted with the usual catch, which would insure the opening being placed in its true position.

After some further conversation,

The Chairman announced, in reference to the copies of photographs to be presented to each member, that the Committee had selected a negative by Mr. Wilson, of Aberdeen, from which the copies were to be printed. As Mr. Wilson was to print them himself, of course it would be some little time

before they were distributed. The next meeting—the last of the year—would take place the day after Christmas Day.

The proceedings then terminated with the usual vote of thanks to the Chairman.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A Meeting of the above Society was held in the Rooms of the Literary and Philosophical Society, 36, George Street, on Wednesday, the 5th instant,—Mr. Parry in the chair.

The Secretary announced that Mr. Dancer would at the next meeting provide the necessary apparatus for exhibiting photographic transparencies by the oxy-calcium light, and members were invited to contribute pictures. It was particularly requested that they should be on the whole stereoscopic plate, for the convenience of adaptation to the lantern.

It would be recollected that at the last meeting a committee was appointed to consider a suggestion thrown out by him in reference to an Exchange Club in connexion with the Society, and he had now to submit a series of rules founded on that suggestion.

The chief objects kept in view were to afford every member means by which he could judge for himself as to the value of the picture he would have in exchange, and to keep up a continuous circulation.

RULES OF THE EXCHANGE CLUB OF THE MANCHESTER PHOTOGRAPHIC SOCIETY.

1. That a portfolio (No. 1) be kept for the reception of pictures offered in exchange, each picture being marked with a consecutive number.
2. That a portfolio (No. 2) be kept for the reception of pictures offered in exchange for those contained in No. 1.
3. That every picture deposited in No. 2 be marked with the particulars of the exchange desired—as, for instance, "offered in exchange for picture No. 1." But more than one picture may be mentioned as desired in exchange; it being assumed that the first-mentioned is preferred, and so on.
4. That pictures designed for exchange shall be delivered to the Secretary, who shall number them, and place them in the portfolios according to the order in which they are received by him.
5. That upon a picture being placed in No. 2, the Secretary shall communicate with the owner of the picture in No. 1 desired in exchange, and if such owner give his sanction, the exchange shall be effected. If the owner of the desired picture do not reply to the communication of the Secretary before or at the ordinary monthly meeting of the Society next following the date of the said communication, then his sanction to the exchange shall be assumed. But no such communication from the Secretary shall be made so as to afford less than fourteen days' notice.
6. That in case there are two or more pictures in No. 2 for which the same picture in No. 1 is required, the preference shall be given to the earliest applicant, as shown by his number.
7. That boxes be provided for the reception of pictures on glass of stereoscopic size.
8. That no picture be admitted which is not accompanied by these particulars:—Subject, process of negative, date and hour of exposure, length of exposure, focus and stop of lens, quality of light, print, how toned; and that the Secretary provide printed forms, to be filled up by the member exchanging.
9. That a picture deposited in No 1 shall not be withdrawn.
10. That there shall not be two prints from the same negative in No. 1.
11. That two or more pictures may be offered in exchange for one.
12. That no member shall have the power of exchanging who has not contributed a print to No. 1.
13. That stereoscopic pictures on paper be mounted; all others on paper unmounted, and not cut round, so as to leave a margin to which the required particulars may be attached.

A discussion then followed on the proposed rules. It was considered that the most probable cause of failure would be a falling off of the quality of the pictures in No. 1; but the general feeling was in favour of trying the system.

Mr. Offer moved, and Mr. Patterson seconded, a resolution to that effect, and it was carried unanimously.

The Secretary read a letter, forwarded byMr. Kirby to the chairman, and accompanied by a number of photographic transparent pictures, burnt into glass by M. Joubert's method. He observed that there appeared to be some deficiency in half-tone, even in those which were copies of engravings; and he believed that transparent photographs taken by the ordinary means were more brilliant; and unless, therefore, they could be produced at an inferior cost, he did not perceive any great advantage in the new method.

Mr. C. Jabez Hughes, of London, remarked that the Secretary had not, he thought, considered the absolute permanence of the burnt-in photographs. The great advantage would be found in their taking a commercial place for the decoration of our house windows, conservatories, and in many similar applications, under circumstances which would speedily destroy ordinary photographs. The previous evening he heard of a case in which a number of negatives were lamentably destroyed by atmospheric influence, although they were kept in a box; how much more then must we expect them to be injured in situations such as those he had mentioned? It was true that in all those processes which are founded upon the use of a chromate, they lost some detail; but then they had secured really good designs, which were permanent.

The Secretary thought that the objection to ordinary photographs could be fully met by covering them with another sheet of glass; but if a further precaution were desired, we had only to cement the two glasses with Canada Balsam.

Mr. Pegg, who had at one time been connected with the manufacture of ornamental glass, said that although M. Joubert's designs were now in one colour only, they might, he believed, be converted into pictures of several colours, by taking them as they now are, and submitting them to several burnings, with as many applications of colouring matter.

Mr. Hughes believed he might venture to say that Mr. Pegg's suggestion had been anticipated by M. Joubert.

A vote of thanks was passed to M. Joubert and Mr. Kirby for their kindness in forwarding the specimens.

A number of transparent stereoscopic pictures, taken by the hot water process of coagulation, were handed round by Mr. Herbert and Mr. Parry. The latter of these gentlemen introduced the pictures to the Society; but it subsequently appeared that Dr. Ryley had previously suggested the process.

Mr. Parry then acknowledged that fact; but said that he believed the thing had never been practically carried out previously to the reading of his paper. He found that it was necessary to keep up the temperature of the water or there were symptoms of blistering. He was not prepared to state exactly what that temperature should be; but he believed that from 180° to 200° would secure success.

The pictures shown were much admired, and there were no symptoms of unequal coagulation of the albumen. A conversation arose as to the degree of density required in pictures for the lantern.

Mr. Wardley stated that they were frequently printed too thin. The best effects were obtained by a fair depth of printing: he had seen some most striking effects from dense pictures.

Mr. Rogerson said that much must depend upon the strength of the light used, and upon the distance of the lantern from the screen. The Secretary asked Mr. Hughes if he could throw any light upon our failures in toning prints upon paper? the complaints appeared to be rather on the increase.

Mr. Hughes believed that the albumenising was conducted as well as it had ever been, but that the new method of toning required conditions peculiar to itself. The chief requirement, he thought, was a fine even surface on the original paper: without that quality the albumen was unevenly deposited, and gave rise to minute valleys which rendered the toning unequal. He had been prevented by the weather from concluding some experiments he had been conducting on this subject, but hoped shortly to resume them.

Mr. Wardley stated that he was convinced, by observation, that albumenised paper suffered in its toning quality by keeping. In a month or two the effect could be found, and in a year or two the paper would not tone at all.

A conversation then arose on the waxed-paper process; and it was generally agreed that the knowledge that they possessed of the principles involved in development afforded reasonable grounds for believing that it might afford most satisfactory results, if as much attention were given to it as was bestowed upon the dry process on glass.

Mr. Hooper and Mr. Rogerson, who have both produced this year some beautiful negatives in waxed paper of a large size—the latter on the whole photographic sheet—stated that one great thing to be observed was ample exposure, there was then but little silver required in the development, the negatives were sufficiently transparent, and that grainy effect so much complained of was avoided.

The proceedings were then brought to a close by a vote of thanks to the chairman.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

The usual monthly meeting of this Society was held on the evening of Tuesday last, the 11th inst., in George Street Hall, Edinburgh. The chair was occupied by T. B. Johnstone, Esq.

The minutes having been read,

Mr. Walker read a few notes on the Macnair process, which he said, for amateurs, was a very good process if carefully manipulated; although he thought that among the dry processes the collodio-albumen, or Taupenôt process, was without a rival, as it gave results which could not be attained by any other. In his remarks he called attention to the chief defects of the Macnair process; which were—liability of the film to crack and peel off in flakes, and a tendency to stain during development. If a collodion, excellently adapted it might be for the wet process, but of a horny, contractile character, were employed in this process, there was no certainty that the film, when dry, would not crack and peel off. The best collodion for this purpose was that which gave a powdery or, as it was termed, a "rotten" film. It could easily be ascertained when it was in this condition by pouring some on a plate of glass, and pushing it forward with the finger. This kind of collodion was prepared by using pyroxyline, made with acids, at a high temperature: it was also necessary that it should contain a larger proportion of alcohol than ordinary. Without collodion of this kind there would be no certainty of obtaining good results by the Macnair process. He always preferred a neutral to an acid bath. With regard to the washing after excitement, he thought it was commonly carried to an excess. Nothing more was required than that the plate be washed till "greasiness" disappeared. More than this he considered injudicious. The strength of the malt solution originally given by Mr. Macnair was too great. The best proportions were two ounces of malt to ten of water: one coating was as good as half a dozen.

He dried the plates as quickly as possible, and when dry he varnished the edges. This prevented the water getting under the film and carrying it off. The exposure in the case of recently-prepared plates was about a third longer than wet collodion; but if the plates had been kept any time longer exposure was necessary. After exposure the plates had to be subjected to a most thorough washing to get rid of the malt; for, if any were left on the plate, a stain in developing would inevitably follow. With respect to a suitable developer he had not yet arrived at a satisfactory result. Iron was cheaper than pyrogallic acid, but it was also much more liable to stain the plate, and in using it there was no certainty of a clean picture. He hoped this objection would yet be got over. Perhaps gallic acid would produce clean pictures; but the time occupied in developing pictures by it was an objection. In fixing, he had formerly used cyanide of potassium; but finding this had a tendency to weaken the negative, he had given it up in favour of hyposulphite of soda.

In the course of his remarks, Mr. Walker exhibited severel stereoscopic negatives containing cracks, tears, stains, marblings, and other defects, as illustrative of the peculiar defects to which he had alluded.

Mr. MACNAIR said he was aware of a good many instances of failures occurring by the splitting off of the film, and he could say from experience it was a most disgusting thing when this occurred with an otherwise good negative. He did not think this was the fault of the preservative, but of the collodion. He proposed, as a remedy, that the plate be varnished over with some vegetable gum, or perhaps with albumen, before the collodion be poured on. He also suggested that a small quantity of grape sugar might be added to the collodion, which would prevent it drying so hard. With regard to the washing after exposure, he considered it absolutely necessary that every trace of the malt solution should be thoroughly removed; but, as it was not easy to know when this was properly done, he would advise that some very powerful vegetable colouring matter—a strong yellow for instance—be mixed up with the wort, and in washing the absence of this colouring matter from the surface of the plate would be a guarantee of its freedom from the preservative.

After some remarks from Messrs. Orange, Nicol, and others, a vote of thanks was moved to Mr. Walker.

Mr. TUNNY then read a paper *On a New Method of Decolorising the Albumen Silver Bath.* [See page 363.]

An interesting conversation followed Mr. Tunny's paper, in which Mr. Moffat and Mr. Nicol took part.

The thanks of the meeting were unanimously awarded to Mr. Tunny for his communication; after which, on a request from the Chairman, Mr. Tunny kindly showed to the meeting the manner in which he made his ammonio-citrate of silver bath, further particulars of which will be communicated in our next.

CITY OF GLASGOW AND WEST OF SCOTLAND PHOTOGRAPHIC SOCIETY.

THE third ordinary monthly meeting of the session of this Society was held in the Religious Institution Rooms, on Thursday, the 6th instant,—Mr. A. M'Tear, one of the Vice-Presidents of the Society, in the chair. The subject of photographic printing, continued from last meeting, was ably opened by Mr. A. Macnab in a paper which we give in another column. [See page 362.]

As several other subjects had to be taken up and disposed of, the discussion on the paper and the subject of printing was briefer than it would otherwise have been.

Mr. JOHN JEX LONG said he had been experimenting a good deal recently on this subject, and he did not see the benefit derived from crystallising silver, seeing they could generally get it pure.

Mr. J. STUART said he had not been troubled recently with the oily marks mentioned by Mr. Macnab; and, when he had, he merely worked on with the bath, and found it disappeared. He adhered to his formerly expressed opinion regarding the best light for printing in. Within the last three months he had made £20 worth of gold into chloride, and found it cost him 1s. 9d. for each fifteen grains. In his daily practice he adopted the plan of throwing down metallic silver by copper wire from the various washings, except the hypo. bath and washings. The silver so obtained he made into nitrate, by adding nitric acid. To this product he added water, and used it for printing. By using a little meter they could test the amount of silver in the bath.

Mr. M'FARLANE asked if there was such a meter?

Mr. BOWMAN said there was, and it had been found to answer very well.

Mr. M'FARLANE said he had asked an optician about this meter, and he was told that no such thing had been discovered as a correct test.

Mr. JOHN CRAMB said the instrument referred to only indicated the specific gravity of the liquid, and consequently the amount of solid contents, if they knew the kind of liquid used, but did not inform them whether they had nitrate of *silver* or nitrate of *potash.*

Mr. BOWMAN said that if Mr. Cramb had put the meter in a thirty-grain solution he would find it stood at 30°.

Mr. JAMES CRAMB said the objection to this meter was in the case of old baths, and not to newly-made ones, which it was known only contained silver and water.

Mr. STUART said he had only recommended the use of this meter to a known solution of silver and water to test its strength.

Mr. JOHN CRAMB reiterated his conviction that the meters referred to were useless, and a snare and deception. Nothing, it seemed to him, but analysis would inform them, with any degree of certainty, how much silver remained in a used bath, and that was almost the only use one had for such an instrument. The use of a solution of common salt, of known strength, and marking how much was required to precipitate all the silver in a measured quantity of a bath, was a simple way of doing so. Though giving his opinion freely on the meter question, he personally felt little interest in it. He had never used a silver meter; possibly his manner of proceeding would have to be called a rough one, but he never felt curious to know what *was in* a bath, so long as it gave good pictures. Before sitting down, he (Mr. Cramb) proposed that the thanks of the Society be awarded to Mr. Macnab for his paper, more particularly as he had been the first to operate before the Society.

The vote was heartily given, and Mr. MACNAB, in acknowledging the compliment, said it had cost him two days' labour to bring those experiments before them.

Mr. J. STUART said there was another matter—that was, the recovery of silver from spoiled prints. In the best-conducted establishments there were necessarily a few spoiled prints. He, of course, had some—one a day, perhaps. These he collected and burnt. By *fusing* the *ash* so obtained with carbonate of soda metallic silver was obtained. Recently he got £4 15s. worth of silver in this way from the waste prints collected in six months; and as some were toned, he also got fully a drachm of gold.

Mr. JAMES CRAMB asked if any gentleman present had recovered the silver from the hyposulphite bath?

Mr. JOHN STUART answered that he had done so, to a small extent, by using the lever of sulphur, which threw down a black deposit.

Mr. J. JEX LONG said that hydrosulphate of ammonia would be found to throw down the silver.

Mr. JAMES CRAMB said the reason he asked the question was, that he had been asking the same question of some gentlemen he thought should have known, and the plans he had got seemed theoretically incorrect.

The SECRETARY suggested that Mr. James Cramb should give the Society the result of his experiments on this subject at the next meeting, as well as the notes he knew he had by him on the hyposulphite of silver.

The next meeting, it was resolved, should be a *conversazione*, to which the friends of members, ladies as well as gentlemen, would be admitted.

The Society afterwards adopted THE BRITISH JOURNAL OF PHOTOGRAPHY as their official organ; and, in connexion with this subject, resolved that papers read before the Society should become the Society's property, and could only be published through the Society's Secretary.

Mr. A. M'TEAR showed a print toned by the recently-published American toning-bath.

After several new members had been proposed, and the usual vote of thanks to the Chairman, the meeting separated.

BRADFORD PHOTOGRAPHIC SOCIETY.

A MEETING of the above Society was held at the Rooms, Chapel Houses, James Street, on Wednesday, the 5th inst.—Dr. R. Parkinson, the President, occupied the chair.

A large number of members attended.

The SECRETARY having read the minutes of the last meeting they were confirmed.

Mr. Smith and Mr. Sutcliffe were duly elected members of the Society.

The PRESIDENT then introduced to the meeting Mr. W. H. LEATHER, who favoured the Society by reading a valuable paper *On the Waxed-paper Process* [see page 365], which excited great interest, and gave rise to an animated discussion.

Mr. LEATHER: Before reading my paper, I beg to observe that there is nothing different, either in chemical preparation or manipulation, from what has, I believe, already appeared in print. Yet it has been my aim to make the paper as complete as possible, so that those parties desirous of making a trial may meet with success.

Several very fine negatives and prints by this process were exhibited.

The thanks of the meeting having been awarded to Mr. Leather for his paper, the Society adjourned until the first Wednesday in January, 1861.

Practical Instructions on Coloring Photographs.

BY ALFRED H. WALL.

CHAPTER VIII. *(Continued.)*

MATERIALS, &c.

VARNISHES.—Good varnishes should bring out the full force and brilliancy of the colours, and be hard enough to preserve the painting from injury. They are prepared chiefly from gums, or, more properly speaking, resins, dissolved in water, spirit, or oils, simple or compounded. Those more commonly used are mastic, copal, amber, and white lac.

Mastic Varnish is easily prepared by dissolving one part of the purest "gum" mastic in three of the rectified oil of turpentine,

and adding one part of fine turpentine. As this varnish is frequently adulterated, and it is advantageous to use the genuine article, it may be worth while, therefore, to prepare it for yourself when you cannot obtain it good. Mastic varnish is very apt to "chill" after application; but, by rubbing it with an old silk handkerchief, the colours regain their brilliancy.

Copal Varnish.—A harder varnish than the former, but somewhat dangerous in use, as it is very liable, from a variety of causes requiring very great care to avoid, to crack. To combat this peculiarity a little linseed oil is sometimes used with the varnish; but this again is objectionable, as on the picture it soon becomes dull and discoloured, and, moreover, causes the varnish, being somewhat of a magilp, to amalgamate with the painting itself, so that there is no chance of ever cleaning or restoring the picture to its original condition. I recommend the use of pure mastic varnish to all who have an interest in the preservation of their work.

White Lac Varnish.—Composed of purified lac resin, dissolved in spirits of wine. The chief value of this varnish lies in its hardness, transparency, and absence of colour. Being a spirit varnish it of course requires warmth to assist in its application. The amateur will experience so much difficulty in using it, that he will scarcely be wise to undertake the management of a material so intractible; but it may be used in preparing the photograph for the reception of oil colours, when it can be applied as follows:—Warm the surface of the photograph; then pour a little varnish into a saucer, and apply rapidly and lightly with a soft linen rag, which has also been warmed. In a few seconds it will be hard and firm enough to work upon. This varnish has another use in photographic colouring, by which I have seen excellent results obtained, even in the hands of very inferior colourists. Wash in the flesh, &c., in the way I have already described in the case of water colours; and when this is done, varnish as above, when, by simply glazing the whole with your oil colours, all the richness and brilliancy of oil may be obtained with the transparent character of mere water-colour washes. The picture so coloured will retain its beauty for many years perhaps, but it must ultimately fade. Colourists who, having no knowledge of drawing, cannot succeed in preserving likeness, cannot fail to retain the resemblance if they adopt this plan. In applying white lac varnish you must be careful that it is not too strong, that you do not rub too hard, and that the painting beneath is thoroughly dry and firm.

Amber Varnish has recently been used to some extent, but I do not recommend it. It has all the hardness and brilliancy of copal, but dries very slowly.

THE PAINTING ROOM.—That is a pleasant sound to me, for although folk curl their lips and nostrils when they enter it, with an outcry against the nasty smells of paint and turpentine, it is to me a charming odorous bower—a retreat from cares, anxieties, and annoyances—in which I can come with a wrinkled brow, and a fretful, impatient spirit, and, sitting down to my work, grow calm, patient, and happy, losing everything else in the absorbing interest of my progressing picture, and feeling fresh pleasure as, under my hand, it grows nearer and nearer to the dear image of my aspirations. Oh! the painting room is a charming place; and you must excuse my digressing in its praise, although I have not the slightest right to do, or excuse for doing, so.

I prefer that my painting room should have a northern aspect, because the light is then less variable, and we avoid the glare of direct sunlight. The window should be lofty, because a picture painted by a low light seldom looks well when seen by a top light. As the tone of your colouring will be affected by the amount of light you work by—pigments appearing different in a good and a bad light—let the window be large.

It is usual to paint with the window on the left hand, because the cast shadow of the hand then falls outward instead of over that part upon which you are working.

Hang up your best works in your painting room, unless you have better work from other hands, as they will reproach you with their mute eloquence whenever, from laziness, want of energy, or any other cause, you are going back instead of progressing.

Whatever you do, keep the room perfectly and scrupulously free from dust, which is the oil painter's greatest enemy. The room should have no carpet, but, in its place, oil-cloth, which can be wiped with a damp cloth every morning. A mat may be placed before your seat, in cold weather, for your feet, as your tenderly-prudent wife, sister, or mother would at once suggest, (what should we do without their careful love?) and nothing should be in your room that cannot easily be freed from dust. More than usual care is required in this respect when the work is so small and delicate in finish as coloured photographs are.

The author of the preceding paper, in order to render his communications of greater practical value, has kindly undertaken to criticise the work of students in colouring, and to give them advice through the medium of these pages; for which purpose specimens may be sent with a stamped and directed envelope *for their return, to* A. H WALL, Esq., 11, THE TERRACE, WALWORTH.

JAMES K.—You have used too much and too thin a vehicle.

A LADY AMATEUR.—You have certainly used the proper pigments, but have mixed them in wrong proportions, thus producing a very comical result. However, as I am really anxious to do my best for pupils in THE BRITISH JOURNAL OF PHOTOGRAPHY, I shall be happy to help you out of the difficulty, if you will send me a large stamped and directed envelope, by enclosing a piece of paper with the tints mixed and applied, by way of guide.

GEORGE GRANT (Kennington).—These "Instructions" will, as I have before said, be published in a separate form.

CHROMO, No. 2.—See the remarks upon lac varnish, or use isinglass dissolved in gin.

A LADY.—You have certainly improved, but the flesh is still too chalky. The quality of "keeping," I am glad to find, has not been neglected this time. The greys are too purely blue. In answer to your question, I can only advise the use of ox gall, and recommend you to try Newman's preparation.

Foreign Correspondence.

Paris, December 10, 1860.

IN the last number of THE BRITISH JOURNAL OF PHOTOGRAPHY I read the note presented to the Photographic Society of London by Mr. Malone, in which he attacks the conclusions drawn by M. Niepce de St. Victor from his investigations on the subject of light. In the interest of my learned friend (whose labours merit the serious attention of Mr. Malone, who seems to be misled) and of science (whose progress demands precision in results), I will, in brief terms, reply to M. Niepce's opponent.

Mr. Malone wished, he says, to ascertain whether the effects obtained by M. Niepce de St. Victor, and by him attributed to a hitherto unexplained action of light, could not be produced without the aid of that agent. For that purpose, what does he do? He takes the heading of a journal, *freshly printed*, and applies it to a sheet of sensitised chloride paper. After an hour's contact, he takes the whole from the frame, washes the sheets of paper with gallic acid, and so obtains a positive image of the printed letters, which he considers to be due to the penetration of the acid wherever the letters have been in contact. "*No light*," he adds, "*was used by me during the experiment*," which he thinks to be "*a simple repetition of M. Niepce's, minus the disputed agent, the light.*"

How is it that Mr. Malone, who is a serious man and a conscientious investigator, does not perceive the insufficiency of such an example? How is it that he does not understand that there is in the result pointed out by him one of those chemical actions which were, in the commencement, brought forward against M. Niepce, and were by him carefully eliminated from subsequent experiments, in order to prove that such chemical actions have nothing to do with his discovery; as he also proved that heat, and the other agents whose effects are frequently identical, have no part in the results which he announces?

As I am convinced of Mr. Malone's sincerity, and of his desire to arrive at the truth, I will ask his permission to indicate a very simple experiment which will destroy all his doubts. Take any engraving, on *sized paper*, which has been kept in darkness during a month, and expose one-half of it to the solar rays, care being taken to screen the other half therefrom, then apply it to a sheet of sensitised iodised paper. The contact must last twelve hours. On developing, you will have a negative image of the insolated portion of the engraving, while the portion protected from the luminous rays will have given no image. No further hesitation can exist, and it will be acknowledged that the light above has acted. Here I come to another objection raised by Mr. Malone. He reproaches M. Niepce with saying that certain bodies *absorb* the light. My friend is not justly chargeable with having so said. He has spoken of the *activity* which the light communicates to certain bodies submitted to its influence, and which enables them to reduce the salts of silver as light. But he does not say—what is very different—that they absorb the light.

It would be well for the general interest that several photographers should repeat the above experiment, or some of those described by M. Niepce, in his papers; but it is important that the instructions therein given should be exactly followed.

The printsellers have lately exhibited in their windows some very remarkable compositions by Mr. Robinson. I was already acquainted with a series of ably-executed works of the same kind by Mr. Rejlander, but I had as yet seen nothing by Mr. Robinson. I was struck by the artistic merit of these interesting productions; and I am happy to record here that the like favourable impression has been produced on the public, who have great difficulty in un-

derstanding how photography can be applied to the execution of such pictures, but who do not admire them the less. It is to be regretted that our own artists have not done more in this line than they have. With the exception of M. Ch. Negré and a few amateurs, who have published a small number of composed subjects, there are only the stereoscopists who have understood what a wide field is opened for photography in this direction. Most of the latter, however, are wanting in that artistic sentiment which is so necessary for such work. I have seen, with great satisfaction, the first specimens of a collection just commenced by Adam Salomon, a sculptor of talent, who is also a first-rate photographer. It consists of studies of expression, types, meditation, reading—the miser, the melomaniac, and others—in all of which may be discovered the experience of a master. The attitude of the model, the lights and shades, the arrangement of the drapery, the very accessories, have that stamp which art alone knows how to impress upon its productions: the execution is marvellous. Thus applied, photography vies with the ablest painting; for there is in these compositions a truthfulness, a fineness of detail, and a general harmony which remind you of the celebrated pictures by Gerard Dow. Adam Salomon will doubtless persevere in this direction; and if he finds zealous imitators among those painters who have adopted photography, we shall soon have works worthy of taking a place by the side of those of Mr. Rejlander, Mr. Robinson, and others.

I have just seen, at Count Sevastianoff's, a small portion of the *clichés* which he has brought back from Mount Athos. His collection consists of 4000 negatives, which he has transferred to paper for the greater facility of transport. I was, I confess, dazzled at the sight of the riches spread out before me: the old manuscripts, some dating from the sixth century, the illustrated bibles, the ancient maps, the *naïve* frescoes of Christian painters of the middle ages, the architectural details of half-ruined chapels, were all reproduced with pious zeal and extreme ability. Should the author publish this magnificent work, a world of treasures will be opened up to archeology, science, and art.

The activity which the approach of New Year's Day communicates to Parisian industry has begun to show itself in the operating-room. The portraitists are besieged by visitors who wish to offer their likenesses in all shapes and sizes by way of *étrennes*. The manufacturers of stereoscopes, and the makers and vendors of stereoscopic pictures, are unable to keep up with their orders, so great and increasing is the demand. In all the stationers' windows the card-portrait album takes its place, with gilded edge and chiselled clasp, by the side of the most elegant articles in vogue. These symptoms prove that the favour which the public accord to photography has increased during the year which is well-nigh gone. For the approaching year let us hope that the new printing processes will become practicable and be generally used, so that we may have to record a still larger development and wider dissemination of photography than in the past.

I close this letter, already grown too long, by wishing all those English artists who have kindly read it and its predecessors a merry Christmas and a happy New Year.

ERNEST LACAN.

New Books.

The Photographic News Almanack; or, The Year-book of Photography for 1861.

(London: Thomas Piper, Paternoster Row.)

We remember having heard of a man who complained of finding the long winter evenings "hang heavy on his hands," and was, therefore, recommended by a friend to amuse himself by reading. To which he replied that he had tried that for a week, but found it *very stupid*. On being asked what books he had read, his answer was—"Oh! a very good book: it was the *Nautical Almanack!*" Now, had this worthy met with the *Almanack* before us, he might have found it more entertaining; as, besides the calendar and list of photographic societies, with the names of the officers and days of meeting, it contains a large amount of "plunder" from the Journals—in most cases not taken bodily, but run through the melting-pot, and presented as a fresh-looking ingot. In employing the preceding simile, we do so only in a jocular sense; for there is no reproach whatever intended. On the contrary, professing it to be a *Year-book*, we think the author was bound to collect from the Journals what he regarded as especially worthy of preservation; and that he has presented the same in his own words, instead of giving a mere copy, testifies as much to his good sense as to his industry. We make this remark feelingly; for we are constantly disgusted by finding in another quarter *our* articles appropriated *verbatim et literatim*, without the smallest shadow of acknowledgment.

Under the head, "Annals of Photography," a retrospective glance is taken at the doings photographic of the past year; and this is followed by various processes and formulæ—whether old, new, or newly modified; and these are given under distinct heads, generally in a condensed and, therefore, useful form. There is also some information about patents, including a list of those connected with photography, granted during the year just closing.

Sundry tables, postal regulations, &c., are inserted as an appropriate conclusion to the preceding matter.

We feel rather amused at being called upon to review what might, in some sense, be regarded as a rival publication; but we take it as being both complimentary to our sense of justice and evidence of the kindly feeling entertained by the editor of a contemporary that we should have had the task imposed upon us.

The editor of this *Almanack* has not scrupled to express his own opinion upon many of the points discussed, instead of placing them drily before his readers; and, although in many of these opinions we do not coincide, and in some hold a diametrically opposite view to that taken by our brother editor, we cordially commend the course he has taken; for a fallible guide must surely be better than no guide at all. In conclusion, we have only to observe that the *Almanack, or Year-book*, is well worth the price charged for it.

The Art of Photographic Etching.

(By W. Strudwick, London.)

The author of this little pamphlet is evidently unaware not only that he is second in the field in his application of photography to the purpose of producing etchings, but that he is behindhand by four or five years at least. The use of a film of sensitised collodion upon a plate of glass for the reception of the original drawing by means of an etching needle was first suggested and applied by the late Mr. Peter Wickens Fry; and we remember to have seen proofs from plates so treated at one of the annual public exhibitions of the Photographic Society—we think in 1855. We have not at hand the file of catalogues, or a reference thereto would verify the date exactly.

We do not think this application of any particular value, as in our opinion a much simpler plan is to make the drawing on paper, and then obtain a negative, either in the camera or by direct contact with a dry collodionised plate in the pressure-frame. By this arrangement the trouble of making the drawing is certainly not increased, while the annoyance of having to reverse it is entirely obviated. When Mr. Fry first introduced the plan we made a similar remark; but at that time the former alternative alone was available, as dry plates were then in the womb of the future.

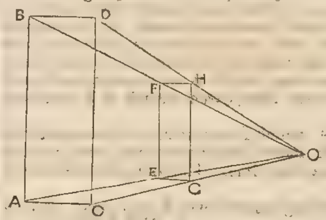
Correspondence.

☞ We are at all times willing to assist our Correspondents to the utmost of our ability, but we can only do so through the medium of the Journal. We cannot give private replies except to personal friends.

PERSPECTIVE.

To the Editor.

Sir,—On reading the report of the proceedings of the London Photographic Society in your last number, I certainly was very much surprised to see the curious misunderstanding there was as to the way vertical lines should be drawn in perspective. It is always supposed in perspective that the plane of the picture is vertical and perpendicular to the axis of the eye. The plane through the eye and the vertical edge of a town is a vertical plane, and will intersect the plane of the picture in a line which will represent on the picture the edge of the town. Nothing can be more evident to my mind than that these two vertical planes will intersect in a vertical line, and that, therefore, the vertical edges of a town will be represented on the picture by vertical lines which will not converge.



Suppose A B and C D to be the vertical edges of the tower and O the eye. The two vertical planes O A B and O C D will intersect the plane of the picture in two vertical lines E F and G H, and E G will be equal to F H. It is quite true that B D will appear smaller than A C, because being further off, the angle B O D is less than A O C; but the eye being placed at O, the proper plane from which to look at the picture, F H will appear less than E G, in exactly the same proportion, and for the same reason, because the angle F O H is less than E O G.

Of course, if the plane of the picture is not vertical, and the axis of the eye not horizontal, vertical lines will be projected on the plane of the picture into lines which will converge and meet in the point where the vertical line through the eye intersects the plane of the picture. In general, parallel lines which are parallel to the plane of the picture will be represented by parallel lines which will not converge, or, in other words, their vanishing points will be at an infinite distance.

I do not think you were right in stating that the single eye was incapable of judging of distance. I think we judge of distance by having to alter the inclination of the axis of the eyes for objects at different distances, by observing that the angle subtended at the eye by any object is less the more distant the object, and by the light, shade, and colour being different for near and distant objects. Both eyes are, of course, necessary for the first of these means of judging, but one only for the others, which are the only means used in giving the effect of distance in a common picture.—I am, yours, &c., A. M.

Hereford, Nov. 23rd, 1860.

[This demonstration is precisely that which we employed.—Ed.

DRY PLATES WITH CHLORIDE OF GOLD.

To the Editor.

Sir,—I am but a few months old in photography, and but a very recent subscriber to your most valuable and interesting Journal; but, seeing the liberal attention which you bestow upon your numerous correspondents, I have ventured to encroach upon your time for a few minutes.

On receipt of Number 130 of The British Journal of Photography, for November 15 (to hand on the evening of the 17th), my attention was attracted to p. 337, where Mr. Mabley is requested by Mr. Petschler to lay before the Manchester Photographic Society the result of a weak solution of chloride of gold poured upon collodionised plates, after washing off all free nitrate of silver; and I determined to make the experiment. On Monday, the 19th, I prepared three plates, exactly according to the method recommended by Mr. John Parry (p. 298), with the exception that they were washed in a large pail of spring water,* with a jug—say eight or ten jugsful thrown very unceremoniously on to each plate—when, after draining for about half-a-minute, I flooded over each plate a weak solution of gold chloride—that is to say, of Mr. J. Stuart's solution (as given at p. 315), "one grain to one drachm," of which I took ten drops to an ounce of common water, and with this very weak solution—three drachms of which were enough amply to cover a plate—I kept it undulating for a minute, drained, flooded with the albumen solution of Mr. Parry, drained, plunged in hot water (a little under boiling), and dried by leaning the glass face downwards against a slanting-sided tin pot full of boiling water. The collodio-albumen coat was soon dry and hard, and I now beg to enclose three proofs of the result.

No. 1 is from the first plate, one hour after preparation, and exposed for fifteen seconds, at 2.30 p.m., with the small diaphragm aperture one quarter of an inch: it was snowing at the time, though the afternoon could not be called dark.

No. 2 plate was exposed the next day, twenty-four hours after preparation in the same way, for twenty seconds, and the sun was shining. I regret having let slip the extra five seconds; but it was done to make sure of getting the bark on the trees, which does not appear in No. 1. I feel certain that fifteen would have done.

No. 3 was taken next day, being one of other three plates prepared in same way, and twenty hours' old, as I had spoiled the last of the first lot. This No. 3 plate was exposed, at about 2.0 p.m., for thirty seconds, the day being rather dark, and clouds very low over the hills, but not low enough to touch the tops of the trees when the picture was taken, and I believe that less time would have done. All three plates have been developed with 1 part pyrogallic and 1 part citric acid, in 250 of water, assisted by the 2 per cent. solution of nitrate of silver, and fixed with the 2 per cent. solution of cyanide potassium, with which they have been very severely treated to remove the yellow iodide. You will see by the colour of the positives that I have got the toning-bath out of order, which is the most bothering part of the whole operation, and generally the most annoying.

The principal object of the present letter is to request that you will be kind enough to give me, in your next number, *a formula for the quickest collodion you know of*, as I go on with my experiments, and have now some hopes of getting a stock of dry plates for the summer, to take views as rapidly as with the wet process, which is so unmanageable and inconvenient on a journey. You see that *fifteen seconds is a very near approach.*

I also beg to enclose you No. 4, which I took with the plates made by the process recommended by Mr. Parry; but the day was dark, and the exposure five minutes, which is a long time. The fixing-bath is the old hypo.

You can make known anything useful which you may find in this letter.—I am, yours, &c., JAMES KENDALL.

Canton de Berne, Switzerland, Nov. 23, 1860.

* This (spring water) contains a chloride, as it becomes milky after washing the plates.

[We are obliged for the preceding communication, which is interesting; but we are of opinion that you err in judgment in supposing that either of the negatives from which you have sent specimens are over-exposed. With the exception of No. 4, they are *very much under-exposed*, and we doubt whether four times the exposure given would have been too much. Even No. 4 is under-exposed, though not very much; but it is far the best of the whole. We have already communicated a formula for collodion, and we now recommend you to alter your developer, in which you employ far too much citric acid—at the present time of the year especially. One quarter of a grain to one grain of pyrogallic will answer at this season; in spring you may possibly want half a grain; and in *very* hot weather what you now employ. In cold weather you will find protosulphate of iron 15 grains, citric acid 1 grain, powdered together in a mortar, then dissolved in 1 ounce distilled water, a good developer. Of course, before pouring on you must add nitrate of silver.—Ed.]

OBSERVATIONS ON TONING.

To the Editor.

Sir,—In reference to your correspondent's, "P. P.'s," remarks on my paper, which appeared in your issue of the 15th November, I have to observe that in them he betrays more ingenuity than honesty of purpose in construing several paragraphs to suit his own purpose, making it appear that I give preference to the old hypo. bath in opposition to the alkaline—a statement which the paragraphs read in their original form will not admit of, as I affirm. If he will be at the trouble of making a correct reading he will find that I give no preference to any of the named baths in point of permanence; but, in placing the merits of the baths in juxta-position before the theory of the President of our Society (see paper *On Influence of Heat and Light*), as before quoted, that the old hypo. bath would bear away the laurels in point of permanence—only, however, if the theory was correct. Even admitting that it is, does the bath receive more laudation at my hands than the others, but only as the old bath has been longest tested? In point of permanence, even with the benefit of a theory which, from the argument brought up to establish it, seems correct, it is still deficient; and, after the lapse of five or six years, the yellow symptoms of destruction appear. As to his longevity of alkaline prints, I don't think that *his experience* will corroborate his remark that *they will be found* as lasting as the most permanent engraving. Three years is but a short span compared with five or six; and because I have a print toned by the old bath three years of age, which looks as fresh as when first mounted, am I to infer that it will last for sixty years? This seems the reasoning of "P. P.;" but experience has proved (with exceptional cases, of course) that they will not last over five or six years; and consequently the presumption in favour of the alkaline bath (so far as age is concerned) is open to controversy.

It will do our friend's heart good to read a paper in your Journal of December 1st, by the Chairman of the Blackheath Photographic Society, on the same alkaline toning in opposition to the old bath, where something like scepticism in regard to durability of its prints appears. Instead, however, of my speaking in a light strain of the merits of an untested bath in point of age, I refer him to the following paragraphs, which seem to have escaped his notice:—"To the honour of the alkaline bath I have found very few failures, so far as regards toning," &c. Again:—"The advantage this bath (the alkaline) has over the *sel d'or* is, that there is less 'bother' in connexion with it, less tendency to engender acid principles, and consequently it involves the chance of rendering the prints a little more permanent, which is 'a consummation devoutly to be wished.'" Further, all the specimens illustrative of the fading away of photographic prints shown by me were by the old hypo. bath, so that I do not think our friend's remarks hold good that I uphold the use of such to my fellow-workers as the best means of preventing decay. But be it borne in mind that, in the present state of our experience, I still maintain that our toning and printing have not as yet gained us anything that we can otherwise but by *presumptive* assurance term permanent.

As to his other remarks, I deem them unworthy of my notice, and leave your correspondent to enjoy the glory of the vituperation given birth to by his own misconceptions and arrogance.

Thanking you for your impartial comments on both papers.

I am, yours, &c.,

Royal Arcade, Glasgow. JAMES EWING.

AUTOMATIC WASHING TROUGH.

To the Editor.

Sir,—The "Amateur Mechanic" writes truly when he says,—"Mr. W. Church seems to be in error as to the action of a syphon, such as described by 'H.;'" but he will have seen by this time that he has not read Mr. Church's letter attentively.

Before "H.'s" letter appeared, I had formed the same opinion of the "automatic syphon" as he had, and when I read your foot note, I began to puzzle my brain about the best method of constructing a self-acting valve such as you named; but before I did so, I determined to give it a fair trial—to do which I procured a box about 16-inches by 12, and about 10 deep. I next procured two pieces of the common lead gas-tube of

different diameters, and used the smaller one for filling the box, and the larger one for the syphon. The box was filled (*i.e.*, up to the level of the bend in the syphon) in about $9\frac{1}{2}$ minutes, and emptied in about 5 minutes. I then flattened the end of the small tube to make the orifice still smaller: the box was filled in about 13 minutes, and emptied in about $3\frac{1}{2}$ minutes. This time the syphon acted for 5 seconds as an overflow pipe, but at the end of that period the water came over and emptied the box as before.

You will perceive from the figures above given, that the syphon tube must have been at least *four* times the capacity of the feed tube. And I think I may safely assert that, within certain limits, in the diameters of the respective tubes any syphon will be self-acting. If a syphon of large capacity should be required, and found not to act, I feel confident that two smaller ones of equal height would answer nicely.

The reason why this syphon acts I take to be somewhat as follows:—Owing to the attraction of cohesion in the particles of the water every vessel requires to be *above full* before the liquid will overflow. This is the case with the tube. Capillary attraction does the rest, and brings the water out beautifully. Hence a very large syphon would not answer, while two smaller ones would.

I am much obliged to "H." for calling attention to the apparatus, as I feel confident it is the very best thing possible for my purpose, and one which even extensive printers may use with advantage.

I am, yours, &c., WATKIN.

REPRODUCTION OF MONUMENTAL BRASSES.

To the Editor.

Sir,—In your notice of my application of photography to copying monumental brasses, in your impression of the 1st inst., you have fallen into an error in describing the negative as being obtained by superposition, which would, even in the smallest brasses, require paper and pressure frames so large as to prevent the process from being adopted on the score of expense, and in the larger brasses this difficulty would be increased almost to an impossibility; for instance, the specimen which you mention as having received from me is a reduced copy of a brass about 5 ft. × 6 ft., the negative having been obtained in the camera by the collodion process, which process has the advantage over the Talbotype of being more transparent in the lights.

By inserting a correction of the above-mentioned error in your next impression, you will oblige.—I am, yours, &c., JOHN LOUCH.

Dec. 4th, 1860.

A RAP FROM A SPIRIT.

To the Editor.

Sir,—Your incredulity relative to the authenticity of spirit-rapping will surely meet with condign punishment.

Wishing to know if either M. Niépce de St. Victor or Mr. Malone were right in the views that they have expressed about "bottled" sunshine, I invoked the spirit of Dean Swift, and inquired whether he could enlighten me. He rapped out his indignation at the doubt, and referred me to Gulliver's Travels, Part III, Chap. 5, which treats of Gulliver's visit to the Grand Academy at Lagado, the metropolis of Balnibarbi, where I found the following:—

"The first man I saw was of a meagre aspect, with sooty hands and face, his hands and beard long, ragged and singed in several places. His clothes, shirt, and skin were all of the same colour. He had been *eight years* upon a project for extracting sunbeams from cucumbers, which were put into phials hermetically sealed, and let out to warm the air in raw, inclement summers. He told me he did not doubt that in eight years more he should be able to supply the governor's garden with sunshine at a reasonable rate; but he complained that his stock was low," &c.

So you perceive that it is not such a very new idea after all.

I am, yours, &c., RAP-PAREE.

SUPERIOR PERMANENCE OF PROOFS FROM PAPER NEGATIVES.

To the Editor.

Sir,—Having long been of opinion that photographs printed in sun light are more stable than those printed in diffused light, I was much pleased at reading, in your report of a recent meeting of the Blackheath Society, a statement to the same effect. I am inclined to go a little further, and hazard a conjecture, that proofs from calotype and waxed-paper negatives may be more permanent than those from collodion negatives, the former requiring longer exposure to the brightest solar light, in order to produce good prints, which, when taken from the pressure-frame, appear literally "baked" into the paper.—I am, yours, &c.,

A WAXED-PAPER MAN.

RAPID FILTERING OF IRON DEVELOPERS.

To the Editor.

Sir,—In the account of the discussion on Mr. Hervé's paper, read at the last meeting of the South London Photographic Society, and contained in your number of The British Journal of Photography for December 1st, I am wrongly reported to have said that the objection existing to slow filtration of an iron developer was that a "*proto-oxide of iron would be formed by exposure to the atmosphere.*"

The decomposition to which I alluded was the formation of a *sub-persulphate of iron*; and I still think that the simple covering of the funnel with a piece of glass is not sufficient to prevent the absorption of oxygen during the passage of the solution from the funnel to the vessel underneath. I respectfully maintain, therefore, that a developing solution containing a proto-salt of iron should be filtered as rapidly as possible, every possible precaution being adopted to prevent contact of air during the process.—I am, yours, &c. J. MARTIN.

[We had noticed the error made by our reporter, and intended to have drawn attention thereto, had not your note been received.—Ed.]

ANSWERS TO CORRESPONDENTS.

Erratum.—In the article headed "Self-acting Washing Apparatus," at page 359 in our last Number, for "axis of the lever," read "*arms* of the lever;" and for "falls on its feet," read "falls on its *seat*."

Fanny.—Omit the acetic acid, and use gallic acid alone.

A Wax-paper Man.—Thanks for your good wishes.

S. B.—We regret that we are unable to view the productions in any other light than that already expressed.

J. H. Slater.—The silver wire dipper will answer your purpose, unless it is very grossly adulterated with alloy.

Troubled Tyro.—We are quite ready to *help* you, but not to write an entire manual for your benefit only. *Hennah on the Collodion Process* is the book for your instruction.

A. M. B.—1, 2, 3. Inquire of Mr. L[illegible]d, philosophical apparatus maker, 11 and 12, Beak Street, Regent Street, London, W. See reply to "Glasguensis."—4 and 5. A few days.

R. T. D.—Johnson and Mattey, Hatton Garden. You will find the lenses that you mention perform the work you require, provided that your chemicals are properly adjusted, and the light good.

Glasguensis.—The use of Professor Way's apparatus for photographic purposes is quite out of the question at its present cost, except as a scientific experiment. Your proofs would cost more than their weight in gold.

J. B. Y.—Your note reached us only on the day when the last Number was "at press," hence it was impossible to reply to you in that. Your sketch is quite correct, except that you have drawn the *negative* too near the *condenser*. The plano-convex of 9 inches diameter will do best; place the *plano* side towards the *negative*.

W. Daniels.—1 and 2. A bi-lens camera; but you must consult our advertisements for the other information. It is not considered fair for us to name any special maker.—3. Dissolve two grains of isinglass in an ounce of water (by heat), and apply by floating or brush. Consult Mr. Wall's articles: the back numbers are to be had of the publisher.

T. J.—The orthographic lens which you indicate will answer the purpose. The stereo-view lens would be much too slow in action. The longer focus that your lens is (if large in proportion) the better result you will obtain in marginal definition for any given size. We do not know the price of Bertsch's automatic camera, or whether it is in the market.

H. H. B.—Hydrochloric acid and water, equal parts. Dissolve therein to saturation, perchloride of mercury. To use the above take a $\frac{1}{2}$ drachm to an ounce of water; pour it on the positive while still wet, and when the whitening is complete, wash thoroughly. Instead of the preceding, some operators use an aqueous solution of perchloride of mercury, to which is added a few drops of perchloride of iron.

Eleve.—1. At an *operative* chemist's, not at a druggist's.—2 and 3. Would occupy too much space to answer; *Hockin's Manual* is what you want.—4. Canson's paper is sometimes very good, but is uncertain. We prefer Hollingworth's.—5. If the streaks are in the direction of the dip, they most likely arise from too early withdrawal of the plate from the bath; if across the plate, they are from hesitation in plunging it in. The *Manual* will answer all your other queries.

O. L. (Cork).—We have been informed by Mr. Maltwood that his camera, described in our last Number, will be supplied to the public by Mr. C. Jabez Hughes, of Oxford Street, London, to whom we must refer you for particulars of cost, &c. The details of manipulation in making micro-photographs are given in papers read before the Photographic Society, 5th Nov., 1857, which may be found in our 4th Vol., p. 245, *et seq.* Mr. Cox, of Skinner Street, Snow Hill, London, has also recently published a pamphlet on the subject.

Draughtsman.—Please refer again to what we asserted, and you will find you have not quoted correctly. That the lines appear to converge *towards* a "vanishing point," when viewed as the chairman supposed, we did *not* deny. We denied that they would *appear to meet;* and so we do still. Because, if the lines be visible at all, much more will the *space between them* (which is by construction greater than the lines), be also visible. Remember, the *visibility of the lines* was a condition imposed by the chairman, not assumed by us.

B. B. H.—For printing glass transparencies we think you will find the Fothergill process all that you can desire for contact printing. For this purpose you had better employ positive collodion, as too great density is objectionable. By developing with pyrogallic and acetic acids a reddish tone is produced—with pyrogallic and citric acids a blueish tone is the result: both are objectionable; but by mixing these two developers in various proportions, several shades of warm browns to purples can be obtained, which generally do well without further toning. If, however, you have a good picture, but of a bad tone, a solution of $\frac{1}{2}$ grain of chloride of gold to the ounce of water will generally mend it. It is not safe to omit varnishing.

James Livesey.—Place your glass concave side downwards on a level table, and around the edge make a *wall* of wax, or gutta-percha, or any similar material high enough to hold a solution over the top of the curve. Dissolve nitrate of silver in distilled water, probably five or six grains to each ounce would be strong enough. Put some honey into a mortar, and add a drop or two of oil of cloves; triturate, and then add water with a little alcohol and mix up. Filter and mix with the silver solution and pour into your glass receptacle, and let it stand for twenty-four hours, when you ought to find a deposit of silver in close contact with the glass. Try a preliminary experiment with a small quantity on a common watch glass. Another plan is to coat the inside of your concave glass with iodised collodion. Fill it with nitrate of silver solution to sensitise, expose to light, and develop by pouring in a solution of photosulphate of iron acidified with nitric acid; wash and dry. Then polish the *inside* with a tuft of soft cotton.—A white opaque varnish is easily made by grinding up *flake white* with ordinary spirit varnish. Some few years back a capital article of the kind was purchaseable at the artists' colour shops, when the ladies were all making old china out of chintz and blown glass by a messy process, which they called *Potichomanie.* Perhaps if you inquire you may still find a few bottles in stock.

J. Wingrave—Thos. O.—"Con Tutto Core"—and F. F.—received with thanks, and will have due attention as soon as pressing matters permit.

Received.—J. Louch. The sketch to which you allude in your P.S. will appear in our next.
